THE City of Bristol is replete with objects interesting to the antiquary and the enquiring traveller, and we subjoin a brief historical account, together with a passing sketch of its principal relics of bye-gone times. It is assumed—but the data are somewhat obscure—that the founder was Brennus, leader of the Gauls and conqueror of Rome, B. C. 388; and his brother, Belinus, is said to have assisted in bringing the foundations of the city to maturity, but this inference is chiefly because their statues may be seen "quaintly carved" on the south side of the tower of St. John's Church in Broad-street, most probably placed there by the *modest* gentlemen themselves in those *refined* times. In the memoirs of Bristol by Mr. Leyer, we find that a British town was founded on Clifton-hill—a picturesque and beautiful suburb of modern Bristol—but the inhabitants and the name were subsequently transferred to a village close by, but that Clifton, after a lapse of one thousand years, is now receiving back its population. Slightly digressing, we must remark that Clifton, which is situated a mile down, and at a considerable eminence over—the river Avon, has obtained a world-famed celebrity for its vestiges of an extensive Roman camp; its celebrated rock of St. Vincent, furnishing some very beautiful spars, petrifactions, &c., and a fountain spa of tepid medicinal water at 76 degs. Fahrenheit, and whitish colour, which has obtained for the place the title of "Hotwells;" also for its suspension bridge, designed by the late Mr. Telford.

Of Bristol Castle, said to have been built by Bishop Godfrey, and by order of William the Conqueror, about 1069 or 1070, scarcely a remnant is extant, though its site has been definitely ascertained at the eastern side of the town, as occupying an isthmus between the rivers Avon and Frome. William Wyrcestre's description of the castle is as follows:

"*The Quantity of the Dongeon of the Castell of Bristow, after th' Information of ——— Porter of the Castell.*

"The tour called the dongeon ys in thyknes, at fote [the foundation] 25 pedes, and at the ladyng place, under the leede-cuveryng 9 feet et dimid.

"And in length este and west, 60 pedes [feet]; and north and southe, 45 pedes [feet]; with IIII toures standyng upon the fowre corners. And the hyest toure callyd the Mayn, id est, mightiest tower, above all the fowre toures, is fyve fethym hygh [30 feet] abofe, and the wallys be in thiknes there, VI fote. Item, the length of the castelle wythin the wallys est and weste ys 180 virgæ [yards].

"Item, the bredth of the castell from the north to the southe wyth the grate garden, that ys from the water-gate to the mayng rounde of the castill, to the walle northwarde towarde the blakfrerys, 100 virgæ. Item, a bastylle lyeth southward beyond the watyr-gate, and contayneth in length 60 virgæ. Item, the length of the bulwark at the utter gate of St. Philip's church conteyneth 60 yardes large. Item, the yerdes called sparres of the hall-ryal [the king's hall] conteyneth yn length about 45 fete of whole pece. Item, the brede of every sparre, at fote, conteyneth 12 inch and eight inch."—p. 260.

After standing for 600 years, it was decreed to demolition in 1655 by Oliver Cromwell—"that distinguished friend of architects and builders."

In 1247, a stone bridge, with lofty houses on each side of it, and a chapel across it, forming a gateway, was built to connect the city and suburbs; but in 1761 this antiquated structure was taken down and replaced in 1768 by the present more suitable one.

By Chilcott's Bristol Guide we learn that

"Besides the bridge at the bottom of Clare-street, and the stone bridge at the head of the quay, there are no less than thirteen bridges of one arch, with houses erected on them, which cross the Froom.

"When the castle, the abbey of St. Augustine, and the priory of St. James were founded, a distribution of the town into parishes appears to have taken place, under the authority of the bishops of Worcester. As piety became aided by wealth, in the growing prosperity of individuals fraternities and parishes vied with each other in re-constructing their churches upon the same consecrated ground. There were likewise perpetual funds for their embellishment, which were constantly replenished, 'ad fabricam,' by testamentary bequests of the more wealthy inhabitants. Chantries for obituary masses were built, as additions to the several churches, to the number in some of them of seven or eight. Upon these shrines and altars the most delicate architecture and carving were usually bestowed, and remained to be destroyed either by the reformers and puritans, or by modern repairs. Several of these churches were very highly adorned in their interior parts. The richest particles of masonry were applied without regard to expense; and the enlarged windows were decorated with stained-glass of curious and brilliant imagery. Those churches in Bristol which are at this time the more remarkable for their beauty, were certainly built about the fourteenth and fifteenth centuries.

---

[*] See page 193 *ante*, and previous numbers.

In an era when stained glass, representing scriptural stories and portraits, were the coveted ornaments of all churches, those of Bristol were probably replete with that species of embellishment. It is not, however, certain that any manufactory of it was established there, but there was at Coventry, York, and London; and much of the finer sort was imported from France and Flanders. From the facility with which it could then be procured by the merchants, we cannot doubt but that it abounded in all the sacred buildings in this town. Very few fragments, however, now remain, excepting in the Cathedral church. Fanaticism at the Reformation, and during the occupation of the town by the troops of Fairfax and Cromwell, and, more than all, the love of destroying and repairing by the same hands, and the interested motives of the repairers themselves, have banished the 'dim religious light' from almost every window; and the churches are *now* fitted up, like lanterns, with raw white or green glass, as evidenced in the windows of the churches of St. Augustine's, St. Mary Redcliff, St. Stephen's, and the Temple."

Further, that of the remarkable buildings for public accommodation and correction, Wyrcestre, in the 15th century, named the following:

"The Tholsylle, where the mayor and common council meet from day to day, as it may be required, under a cover of a ceiling leaded over, opposite to the west door of Christ Church. Upon the bridge there is a fair and large room, beautifully vaulted, beneath St. Mary's Chapel, for the session of the sheriffs and jurats of the town to consult for the public good."

"The Council House for the mayor, sheriffs, bailiffs, and principal merchants, is situate on the open space above the Tholsylle, opposite the chancel of All Saints' Church."

"The Pillorye, near the oldest gate in the wall, in the middle of Wynche-street (Wine-street), is a round building, handsomely constructed with freestone, both for dimensions and height, with chambers and windows artificially barred with iron: and upon the platform of the roof of this building is erected a *collistrigium* of timber frame work, in order to *collistrigue* or pillory infamous men, especially dishonest bakers."

Rambling through the town numerous quaint or elaborately carved timber framed dwellings, with projecting stones, barge boards, &c., and whose construction would be regarded with curiosity and afford an instructive lesson to our modern carpenters—present themselves. The merchants' houses had cellars extending the entire basement and for the storage of goods, and the business surface thereby obtained under ground nearly equalled that above. On the ground floor were the "shopæ" or stalls, with "aulæ" or halls communicating, and on the first floor were the "parlura, coquina, and camera," the proprietors' chambers, together with sometimes an apartment in the roof termed "solaria."

The churches of St. Mary Redcliff, St. John, St. Werburgh, and St. Stephen, were built by private individuals, W. Canynge, Walter Frampton, Walter Derby, and J. Shipward, respectively all mayors of Bristol, and the former—which we shall presently describe— is one of the most venerable, extensive, and costly architectural structures in the United Kingdom.

The Cathedral is a venerable structure, and was originally a monastery dedicated to St. Augustine in 1148, Sir Robert Fitzharding having begun the foundation in 1140. The gateway has been considered as the only vestige of the *original* structure; and, from its great beauty, has attracted much notice. The chapter-house, however, and part of the cloisters, are evidently Saxon, and most likely coeval. The present cathedral, consisting of a neat choir, fitted up in the gothic order, with part of the nave and the two side aisles, *all of equal height*, produces a most singularly beautiful and grand effect. It is, however, one of the smallest cathedrals in England; but it has a certain singularity in its interior construction, which produces considerable beauty and picturesque effect. In external height, the aisles equal the nave. Instead of arcs boutants, or flying buttresses, a complicated structure of crossing arches occupies the roof, and supports, in their stead, the side walls of the nave. Of this plan we know not of any other instance. The monuments in this cathedral are very numerous and interesting.

Redcliff Church is built on a red sandy rock or cliff—from which it derives its name—with stone dug at Dundry, about four miles and a half from Bristol. It is allowed to be the finest parish church in England; and is, as Chatterton calls it, "The pryde of Bristowe and the Westerne Londe." To this stately edifice there are three principal entrances by a flight of steps of Purbeck stone, viz., a north, west, and south door. The tower, which is richly ornamented by a variety of carved work, is nearly two hundred feet in height, has a noble peal of ten bells, and formerly contained a lofty steeple. On viewing the outside of this church, its appearance is majestic and venerable; and on entering it, its lofty vaulted roof, which is all of stone, and every where carved with devices and ornaments of curious workmanship—its long middle aisle, terminated by the chancel and altar—its noble pillars, which are inimitably wrought into the most delicate mouldings—and indeed, the exquisite beauty and lightness of the whole fabric, excite feelings of admiration and delight, and instinctively, as it were, awe the mind into a devotional feeling.

There are four palpable varieties of Christian architecture in Redcliff church, manifesting as many architects, and as many different times when they were respectively designed and erected. The inner north porch, or vestibule; the tower and spire; the outer north porch; the body of the church, with the lady chapel, and the south porch, we feel assured were built successively; and it is generally admitted, that an older church was removed to give place to the present nave and chancel, with their aisles, and the transept. The oldest of these members, *i.e.*, the vestibule, is of a date between A. D. 1200 and 1230.

The tower contains a diameter of 23 by 24 feet. Its height is 120 feet, and with the spire, as it now remains broken by a storm, is 200 feet high. The diameter, at the top of the fracture, is 16 feet, and it has eight panes or sides. Every stone at the beginning of the spire is two feet thick; but at the top of the fracture only four inches. The diameter of the "garlonde" [the parapet round the summit] where the cross is placed, is 11 feet. Thickness of the walls at the foundation is seven feet, and five at the top of the tower.

The whole length of the church is 63 yards, exclusive of Our Lady's chapel. The breadth is 18 yards; total. 231 feet. The said chapel 13 yards, one foot and a half by 21 feet.

The length of the first gate or north porch is seven yards, and the chapel continued from the gate of entrance, is six yards more.

The height of the arched and fretted vault (voltæ frettæ archuatæ) of the nave and aisles, and likewise the aisles of the transept from north to south, is 80 steps from the ground, from information given me by the plumber, on 7th Sept. 1480, each step containing eight inches at least. The length of the transept 67 paces. The aisles are 26 paces. The chapel of the north porch contains in circumference 44 yards, and is ornamented with the statues of the kings, (cum ymaginibus regum operatis subtiliter in opere de freestone.)

Between each pillar and arch there is a space of 10 feet. The transept has eight arches: every window in the "ovyr-storye' has five glazed divisions, and is 10 feet wide; and those in each aisle have three. There were six bells in the tower, the largest of which weighed 7,024lb. avoirdupois, and the smallest 1,300lb. weight.

In the years 1445-6, about St. Paul's tide, 100 feet of the steeple were thrown down during a violent storm of thunder and lightning, and falling upon the body of the church, it became almost a ruin. To the "everlasting prayse" of that worshipful man William Canynge, who undertook to repair, enlarge, and beautify the edifice, founded by his ancestors, we behold this fine church nearly all complete. The steeple was not rebuilt—a fortunate circumstance, perhaps, since the lightning, but a few years since, dislodged some large stones from the top of the tower.

A beautiful gothic screen to the front of the gallery, corresponding in architectural character to the whole building, was erected in 1841, chiefly by the spirited exertions of Mr. W. Ringer, one of the then churchwardens.

The church was newly pewed and beautified by brief, in 1709. It was again repaired, and the pinnacles on the south side rebuilt in 1796; and very recently important restoration works have been carried on under the direction of Mr. George Godwin, architect.

There is a large bone preserved at the west end of the church, which is said to have been a rib of the *dun cow*, slain by Guy, Earl of Warwick!!

Some very ancient grave stones and monumental brasses are preserved.

The Chatterton memorial, lately erected by subscription, is placed in the enclosed spot at the north-west angle of the churchyard, between the tower and the north porch. It is pentagonal on the plan, raised upon three graduated steps: from the base it is divided vertically into three compartments, the lowest is intended to contain the inscriptions, with buttresses at the angles, which rise up to the head of the next division, the space between them being occupied by a deep niche. In the centre niche is an open scroll, inscribed, "The Poems of Rowlie." The canopies of these niches and the buttress tops are richly carved with flowers and grotesque animals. The third compartment is formed of five small pillars, with ogee-arched heads and carved spandrills, and a central pillar for the support of the statue. These are surmounted by a deep cornice, with heads and flowers at the angles, and a pedestal cap. The figure of Chatterton crowns the monument; he is represented in the dress of Colston's school, where he was educated; from his left hand falls a long scroll, inscribed, "Ella, a tragedie."

The character of the monument assimilates to the design of workmanship of the buttresses of the north porch. The total height is 31 feet, and its cost was about £100.

CORPORATE INTERFERENCE WITH THE RIGHTS OF ARCHITECTS.

THE COUNCIL CHAMBER, CITY HALL.

AT a recent meeting of the Corporation we find the following:—

Mr. Whelan submitted a plan which *he* had prepared for remodelling the council chamber, and suggested that it should be adopted on the principle of competitive examination.

Alderman Reynolds had no objection to the plan being referred to a committee. He was happy to be able to say that he and Alderman Roe had been asked to see a plan by Mr. Neville. It was most fortunate that Mr Neville happened to be in London, for he was able to get the plan of the House of Commons (laughter). That might excite a smile, but the House of Commons had the advantage of the best skill, and they could not do better than adopt the plan of the House of Commons in miniature. They ought to have that council-room so as that it would be a model worthy of imitation, and he would, therefore, be a party to sending the plan to a committee summoned specially for that purpose.

Mr. Martin (Fitzwilliam Ward) said that as his lordship was to be placed in a position similar to the Speaker of the House of Commons, he thought it well to remind the house that there would not be room for a "cage" for the ladies (laughter).

We apprehend that in this matter there is tampering with the rights of others. Mr. Whelan may be a very excellent municipal legislator, as also a very competent builder, for aught we know; but within the corporate walls he should not seek to blend the *two* capacities, and while enjoying the councillor's toga, volunteer likewise the office of "an architect." Mr. Neville holds the appointment of city engineer and local surveyor, and no doubt very efficiently; but there is a *city architect* likewise, on whom any matters connected with building alterations, &c., would appear more consistently to devolve than upon an engineer or surveyor, who, we assume, has quite enough to do in his own legitimate occupation to engage his attention. If the office of city architect to the corporation of Dublin be a mere *honorary* title, and that the engineer is to do *his* duty, better abolish it altogether, and get rid of the "mockery"; but, if it be a *bona fide* appointment, the holder should enjoy the gain as well as the name, and his province not be intruded on. We have no reason to assume that the city engineer *volunteers* his services in any capacity to which he is not strictly and honourably entitled; indeed, on the contrary, judging from both his private and professional character, we believe he would scorn such an act,—so no *personal* inference must be drawn from the foregoing remarks. What if the city engineer in London were called on to give a plan for altering the Guildhall, or other municipal building, and Mr. Bunning, the city architect, be passed by? English blood would boil, and the council demand satisfaction for the innovation. The case is identical here, and we hope to see each man occupy his "right" place. An appropriate motto for adoption amongst corporate officers, would seem to be "Ne sutor ultra crepidam."

EXTENSION OF LOWER DOMINICK-STREET.

AMONGST the many municipal improvements which suggest themselves to our usual review, none appears much more desirable under present progressive circumstances, and when the great transatlantic highway may fairly be designated the *national* topic, than that the approach to the Midland Great Western Railway terminus—one of the great arteries—from the chief thoroughfares of the city should be divested of every incumbrance. To effect this more perfectly than at present—when a circuitous route for vehicles is indispensable, and not a very pleasing mode of access afforded to pedestrians from certain localities by bye-lanes or streets of indifferent character—would be to continue, of equal width, or nearly so, Lower Dominick-street to Henry-street. The western side of the former ranges pretty closely with Cole's-lane, and by producing the eastern on a line now occupied by the sites of the houses in Britain-street—viz., 42, 43, and 44—thence to Henry-street, where Nos. 51, 52, and 53, at present occupy positions, a width of 60 feet of thoroughfare, or thereabouts, exclusive of Cole's-lane, would be obtainable. This would undeniably open up a spacious street for public and private business purposes, and be a decided improvement both to the locality and the city generally. What a desirable site would then present itself for a metropolitan market? by dispensing with Moore-street altogether, and substituting, in the intervening square, a properly-arranged covered area in lieu of the heterogeneous, inconvenient, unhealthy, and uncleanly disposition of shambles and shops for potables now in existence.

MANUFACTURE OF DRINKING FOUNTAINS.

FEW movements of late years have so successfully and simultaneously attained the double purpose of contributing to the requirements of a large section of the community and opening up an emulative field for artistic progress, as that for establishing drinking fountains in cities and towns. In London, Glasgow, Liverpool, Manchester, and various other towns in England and Scotland, some architectural acquisitions of this class have been erected; but, slow as we Dubliners are generally in matters of improvement, those erected by us—however laudable the intention—are, in an artistic view, a positive disgrace to our city. In the hope of effecting some reformation in the taste at present displayed, we devote several pages of this publication to the illustration of what *has been* done elsewhere, and what clearly yet remains for us *to do.* It will be seen that this character of structure is capable of a variety of treatment, each contributing more or less both to embellishment and utility. In addition to the "mural" fountains already described at page 212, we illustrate a design (see page 216) for one in cast iron, also intended to be fixed against a wall, and provided both with a "drinking tap," chains, and cups, and a dog trough below, with an overflow outlet to prevent flooding on the street. The price of this would be about £3. For isolated fountains, see the figure next to that described, which illustrates a design in pillar form to be erected on a footway, and with a dog trough surrounding the base. This design was adopted in public competition by the Commissioners of the Glasgow Corporation Water Works, and has been placed in several wards of the city. A pillar fountain of this fashion, and 3 feet 6 inches in height, is obtainable for £3 5s. The illustration at page 218 displays a design for an isolated fountain, combining also, by a very clever treatment, an ornamental lamp-post, and thereby serving a double purpose. The body is of octagonal form, and the capping of the pedestal receiving the waste water from the tap forms a basin for washing hands, or, if desirable, can be sufficiently enlarged for a horse or cattle trough. The dog trough at bottom is better protected from probable pollution of the water by accident than in the other instances. The arms of the lamp, by a slight modification, might also be used—as in London—as indicators of thoroughfares; or portion of the shaft and pedestal for advertising media injudiciously arranged pannelling or other contrivance. How many desirable sites present themselves in our city for such a construction as this? For example, at the end of Sackville-street, next Carlisle-bridge, the junction of D'Olier and Westmoreland streets, Barrack or Thomas streets, the squares, &c. The designs at pages 219 and 221 are for *jets d'eau* and drinking fountains, likewise applicable for a public *place*—such, unfortunately, as Dublin cannot boast of—like Paris, Brussels, London, Manchester, and other cities, for parks, pleasure gardens, &c. What an improvement if such as these were introduced in the area in front of Trinity College, and the old railing replaced by a new one? The water in design at page 221 is intended to fall over eight different outlets in basins, though not shown herein. The prices are respectively £25 and £30. What a boon, if at our cab-stands and railway stations, our cattle markets and localities adjoining the shipping, fountains for thirsty brutes were placed at intervals? And what a shame that it is not so? Foremost amongst the manufacturers of this class of structure are MESSRS. GEORGE SMITH & Co., of Sun Foundry, GLASGOW, to whom we are indebted for liberty to publish these designs, which we may remark are *duly registered.*

PEAT GAS IN MULLINGAR.

IN the course of an address from the shareholders of the Mullingar Gas Company to Mr. R. L. Johnson, patentee of the process by which the town has been recently lighted with gas obtained from common turf, we find the following paragraph:—

"We now gladly bear testimony to the complete success of the undertaking. We beg to say that the gas obtained from the turf peat far exceeds our expectations, and we joyfully congratulate you on the result of your discovery; and further, we fondly hope that many other towns throughout Ireland, particularly the more inland towns, and those situate in the vicinity of extensive bog districts, will avail themselves of the treasure which Nature has so bountifully put within their reach, by lighting their respective towns with peat gas, and thus give a stimulus to home industry, which is one of the most effectual means to ameliorate the social condition of the people."

Mr. Johnson in his reply remarks—

"Your high testimony to the satisfactory manner in which the gas works have been inaugurated with turf gas, possesses, for the lovers of Irish industrial advancement, considerable importance. My first experiments were made with a few pounds weight of turf only and a gas receiver, the contents of which were a cubic foot. The consumption of turf in your town for gas purposes is at present considerable, and your gas receiver contains nightly *ten thousand* times the quantity of gas to that produced in my first experiments; the gas, too, passes, as required, through more than 25,000 feet of piping."

We believe, from the peculiar applicability of this invention to numerous and extensive districts in Ireland, and opening up, as it must of necessity, an important field for employment of the poor, it deserves to meet with every encouragement.

GAS IN THE PROVINCES.—The Town Commissioners of Tuam have granted £500 towards the expense of introducing gas into that town.

WEXFORD MECHANICS' INSTITUTE.

A NEW Mechanics' Institute has just been finished in Wexford by Mr. Richard Pierce, builder. Little can be said for the architecture of the design, which is a local production, supplied to the Committee gratuitously with a view of obtaining the contract, and, as usual in such cases, proving to be *dear* in the end. The building consists of a hall (in which are to be placed the books of patents, for the in-inspection of the public), library, and reading-room, committee-room, museum, and librarian's apartments. The structure is a prominent feature in the principal street, and its external appearance has been improved by an alteration of the builder's in front. Cost £500.

Monthly Railway Memoranda.

Bagenalstown and Wexford.—By this bill it is proposed to enable the company to make a railway from their main line at Shanahona to Enniscorthy; also a railway from their main line at Clomony to Ballyellin quarry; and an approach road from the quay to New Bridge, and to the authorized terminus of the company, at Wexford. To be completed in five years.

Cork and Kinsale Junction.—The contractors have been put into possession of nearly one-half the length of land required for the railway, commencing at the point of junction with the Cork and Bandon line, and terminating at the summit station beyond Templemichael, a distance of nearly five miles, and the works on this portion of the line are progressing rapidly. The board are of opinion that the railway could be completed by June or July next to within five miles of the town of Kinsale. All the necessary arrangements had been made by an independent company for commencing the building of the proposed marine hotels and baths at Kinsale forthwith.

Cork and Youghal.—This line will be opened in a few days to Killeagh, and in all probability to Youghal, by next May. A station will be erected at Mogeely, close to Castlemartyr, and between Midleton and Killeagh. The works of the Queenstown branch will be commenced immediately.

West Cork.—It is proposed to incorporate a company for making a railway in the county of Cork, to consist of the following sections—viz., a junction with the Cork and Bandon Railway, near Bandon, to Ballineen; line from Ballineen to Dunmanway; from Dunmanway to Dromdaleague; from Dromdaleague to Skibbereen. To be completed within five years. The capital of the company to be £200,000.

Dublin and Belfast Junction.—The additional portions of second line have been opened for traffic, so that the double line is now complete from Drogheda to Newry main line station, and contracts for rails and sleepers for an extension of the second line thence to the junction of the Banbridge Railway at Scarva, a distance of ten miles, have been recently concluded on favourable terms; the work will be commenced as soon as possible, and when completed there will remain only eight miles of the line to be doubled. The directors have contracted for the erection of 12 houses on the company's land adjoining Dundalk station, for the *employés* on the locomotive works.

Dublin and Drogheda.—The objects of the proposed bill are to enable the Dublin and Drogheda Railway Company to make a railway from a junction with the Navan and Kells branch of their railway at Kells to Oldcastle, in the county of Meath. To be completed in five years. The engineer reports that preparations are in progress for the renewal of the Malahide viaduct in the course of the present year.

Dublin and Meath.—The objects of this bill are to authorise the Dublin and Meath Railway Company to abandon the construction of their authorized line between Piercetown and its intended junction with the Midland Great Western of Ireland at Clonsilla, and in lieu thereof to make an extension from the remainder of their authorized line into St. George's parish, at Dublin. To be completed within five years. Between Navan and Kilmessan the earthwork is nearly all completed, and the line fenced in. Two public road bridges have for some time been open to the public. Two others are also in a very forward state, and will be open for public traffic immediately. The bridge over the River Boyne, consisting of four arches of 85 feet span, and two arches of 28 feet span, is nearly finished. A new mill-race has also been formed. The works on the branch to Trim and Athboy have not been increased since last half-yearly report, with the exception of making some level crossings and putting up some field gates. The line between Navan and Kilmessan could be formed, and the rails laid in six weeks or two months, and the whole line from Navan to the Black Bull, where the extension into Dublin is proposed to commence, could with ease be completed and ready for traffic by the middle or end of October next.

Dublin and Wicklow.—It is proposed to change the name of the Dublin and Wicklow Railway Company to "The Dublin, Wicklow, and Wexford Railway Company." To enable the company to make an extension railway from a junction with their authorized line to Gorey at Clonatin Lower to Templeshannon, near Enniscorthy, in the county of Wexford. To be completed within five years. The turn-tables, carriage-dock, and sidings at Harcourt-street terminus, have been completed; the second line of rails has been laid from Dublin to Dundrum; and the branch to the Jetty at Kingstown has been completed and opened for public traffic. Some alterations are being made at Westland-row terminus to facilitate the English traffic and the conveyance of mails.

Dundalk and Enniskillen.—The Cootehill extension is expected to be open for public traffic by August. The working plans of the Clones and Cavan extension are ready, contracts advertised for, and all other necessary steps taken to have the work completed by the time specified. The works on the main line have been taken up from the contractors, except the last four miles, which, by arrangement, are maintained to the 14th instant at their cost. The renewals of permanent way have been necessarily large, but not more than were required to maintain the line economically in good working order. The terminal station at Enniskillen, as already described in the DUBLIN BUILDER, has been completed, and small stations at Monaghan-road and Maguire's-bridge are in progress. The works on the Cootehill branch are progressing favourably. 190,000 cubic yards of earth have been moved, and 5,000 yards of rock; 18,000 lineal yards of fencing have been erected, and 720 yards of culverts and drains have been put in. New bridges have been built, containing 3,900 cubic yards of masonry. The whole of the Clones to Cavan and Belturbet line, with Belturbet branch, has been laid out carefully and lockspitted.

Waterford and Limerick.—It is proposed to enable the Waterford and Limerick Railway Company to make a tramway from their main line to the market-place at Limerick; an extension railway from the terminus at Waterford to the River Suir; and a pier or wharf on the north bank of the River Suir. To be completed within four years. To dispose of the bridge over the River Suir at Fiddown.

Notes of New Works.

METROPOLITAN.

The National Gallery is ready for roofing, and estimates are required according to plans and specifications to be seen at Sir Richard Griffith's office, 6, Ely-place.

St. Anne's Parochial Church is undergoing alterations and repairs, shall we say improvements? This structure—fine and venerable even in its incomplete state and without its lofty superstructural Palladian pediment and staged spire, as intended by the original design—is one of the oldest of our churches, and demands more important restorative works than are now being proceeded with. The exterior is undergoing a painting process by way of preserving a clean face, but no steps are being taken to remedy the eyesore of a blank wall following rake of the roof, and surmounting an entablatured façade, having much architectural pretensions of the old school. Internally the galleries are being reconstructed after the same fashion, in same position, but with a range of timber columns with metal cores and floriated caps to sustain the bressumers; windows also have been introduced to light the aisles, but the necessity for this appears very questionable, in as much as their previous darkness was owing to the extreme lowness of the galleries—9 feet in height—and had they during the progress of reconstruction been elevated some 3 or 4 feet, the light from the present spacious windows would have, to our mind, proved ample, and their proportion have been far more consistent with the general internal elevation of the church. In the west wall a large niche has been formed for the reception of the organ, a new Caen stone pulpit erected, the apsidal floor laid with Minton's encaustic tiles, and various works of lesser character effected throughout. The ceiling is of waggon shape, and capable of receiving characteristic ornamentation. The contractor is Mr. Hall, under the directions of the Ecclesiastical Commissioners architect; the Parish and other resources, being as we are informed, as is unfortunately too frequently the case, insufficient at present to accomplish all that might be desirable; the expenditure being about £2,000. As regards the facade our remarks are peculiarly applicable to St. Thomas' and Werburgh's churches likewise.

PROVINCIAL.

A new convent has been erected at Dungarvan, Co. Waterford.

The foundation stone for the new schools about to be erected at Tuam by the Christian Brothers has been laid.

The Dundalk and Enniskillen Railway Company purpose proceeding immediately with the construction of their line between Clones and Cavan. Tenders will be received till 6th inst.

The Grand Jury of the Co. Mayo, for the improvement of the harbour of Killala, have advertised for tenders for deepening and straightening the channel from the pier-head to deep water; likewise for repairs of the pier of Clare Island and Bay, Co. Mayo. Henry Brewster, Esq., C.E., Castlebar.

The Corporation of Drogheda will receive, up to the 30th inst., proposals for the erection of one or two drawbridges across the River Boyne.

Additions and alterations are to be made at the court-house, Enniskillen; cost not to exceed £2,500.

A new church of a very splendid character is to be erected at Piltown, on the property of the Right Hon. the Earl of Besborough.

Driminiskil Church, near Florence-court, is to be completed, and tenders will be received up to the 1st of March.

Correspondence.

[ADVERTISEMENT.]

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR, – It being thought by many persons that *I* was the plaintiff in the case of O'Reilly v. Brennan (Court of Exchequer). I beg to apprise the readers of your journal that I have no connexion with the party bearing a similar name, and shall feel obliged by your inserting this in your next publication.— I am, sir, &c.,

EDWARD O'REILLY,
25th February, 1860. 100, North Brunswick-street.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR,—It is apparent that from the expense of architectural and engineering works most of the junior members of the profession are debarred from obtaining a suitable library. And, with a view of bringing the more expensive publications to some, by means of a moderate annual subscription, I would suggest that an association be formed on the principle of "Art Unions," for the purchase of architectural and engineering works, with annual distributions of money prizes, each subscriber of 10s. to have one chance of a prize. The holders of prize tickets to select the works. subject to the approval and through the committee. I am sure the majority of the profession would join such an association, and for its success only requires the valuable notice of the building press.—I am, sir, your obedient servant,

C. E.

Londonderry, February, 1860.

THE SHILLING ART UNION OF DUBLIN.

The success which has attended the Art Union lately established by the French government in Paris, at one franc a share, has induced the formation in Liverpool, Manchester, Birmingham, and other large towns of Art Unions, at a shilling subscription, and the results have been most satisfactory. 34,000 subscribers have been obtained in Liverpool, and pictures to the amount of £1,800 distributed as prizes. As such societies are peculiarly adapted for diffusing a more general taste for art, and spreading its refining influences amongst all classes, it has been deemed advisable to establish a similar association in Dublin, and a committee has been recently formed to arrange and carry out the necessary details. The Art Union is to be based upon the money prize system; each prize-holder to have the right to select for himself from the Dublin Exhibitions a picture or work in sculpture to the value of the prize. The shares to be one shilling. The drawing of the prizes to take place on the 1st of June, and the highest prize not to be less than £100. Mr. White observed that it might be supposed by some that this society was established in opposition to the Art Union of Ireland; but such was not the intention or wish of its promoters. The only rivalry ought to be, which should do the most to advance the arts in Ireland.

WAR DEPARTMENT ARRANGEMENTS FOR BUILDERS.

BUILDERS tendering for government contracts in the War Department are by a recent arrangement supplied with the quantities of the works required, and are not subjected to the troublesome and expensive previous process of each having to prepare his own calculations of quantity,—now it is only a matter of pricing an account. Competition is greater under the present system, no doubt, and prices lower; but against this there exist facilities and advantages of much importance, both as regards the taking and working of contracts and the final settlement of building accounts. Eminent surveyors, selected by the government, in England, Scotland, and Ireland have contracts for supplying the quantities at the usual percentages for such works, viz:—

30s.	per cent. under	£10,000	20s.	per cent. under	£75,000
28s.	„	20,000	19s.	„	100,000
26s.	„	30,000	18s.	„	125,000
24s.	„	40,000	17s.	„	150,000
22s.	„	50,000	15s.	„ above	150,000

The per-centage is paid on the amount of the accepted tender; and when no tender is accepted, or when any portion of the work measured is abandoned or postponed, one quarter per cent. less is paid on the part abandoned or postponed. For works not exceeding £5,000 the government surveyor and his assistants alone make the quantities, and the whole per-centage is paid to him. For works over £5,000 a second surveyor, appointed by the contractors, joins the government surveyor, and the two perform the service between them and divide the commission. The surveyors and their clerks are allowed their travelling and hotel expenses, when any are incurred, and three guineas per day to each surveyor for time lost in travelling.

The Government Surveyor for Ireland is Mr. E. P. Gribbon, Architect, of 57, Lower Gardiner-street, Dublin.

RUMOURED ELEVATION TO THE PEERAGE OF PROFESSOR COCKERELL, R.A., ARCHITECT.

ONE of the most gratifying incidents connected with the history of the architectural profession in this century will be the payment of a tribute—honourably earned—to this distinguished and erudite professor of architecture, zealous antiquarian researcher, eminent author, and polished gentleman The venerable professor may be designated the "Father" of *our* bar; and his recent election as President of the Royal Institute of British Architects, after the demise of Earl De Grey. confirms him in his patriarchal position,—one, however. which he modestly *thrice* declined, believing it might be filled with more advantage to the body by a nobleman. Such an act of self-denial has it is said suggested in high quarters the reward of its *nobility*, an act which, when consummated, will be universally appreciated as a gracious distinction by a "gracious" donor, and be recognized as an additional incentive to "art and artists" to those so liberally offered during the reign of Her Majesty. It is usual on the elevation of a successor to the presidency of the Royal Academy that he "be dubbed a knight"; the same rule is observed as regards the bench, and the attorney and solicitor-generalships in England, the latter so frequently but a temporary position; but, with few exceptions, the other learned professions are not even so honoured. The architectural points with much pleasure to an efficient representative in the House of Commons in the person of Mr. Tite, M.P.; and we doubt not that among the "ermined lords" the newly elected peer will maintain a dignified position, and carefully guard the interests of the profession, now so extensively intruded upon.

THE VICEROY ON THE IMPROVEMENT OF DUBLIN.—His Excellency the Earl of Carlisle in the course of his, as usual, happy address at the Lord Mayor's inauguration banquet on the 20th ult. made the following remarks relative to metropolitan progress: "No one can walk the streets and squares of this metropolis without being struck with the great improvement in the appearance of the shop fronts and the buildings which are springing up in so many quarters, and I trust you will persevere in adorning your noble spaces with more statues of her most eminent poets, warriors, and statesmen; and altogether, not to intrude upon you longer, I feel that the Ireland of to-day deserves a large share in those noble lines, which were addressed to an Irishman of a former generation:—

"Bid harbours open—public ways extend,
Bid temples worthier of the God ascend;
Bid the broad arch, the dangerous flood contain,
The mole projected break the roaring main.
Back to his bounds the subject sea command,
And roll obedient rivers through the land;
These honours, peace to happy Britain brings;
These are imperial works, and worthy kings."

His Excellency likewise briefly alluded to the "water supply," without however pronouncing any opinion on the present project, and stated that "he is at present engaged in erecting a drinking fountain."

The Tramways to the Quays, Belfast.—The directors announce that the project of a tramway from the terminus to the quay has been abandoned for the present.

New Church at Clontarf.—We understand that a new church is about to be erected near Dollymount, Clontarf, in order to afford sufficient accommodation for this extensive suburban district. The church at Clontarf holds only 350, while the Protestant parishioners exceed 1000. To meet this want the parochial clergy have been obliged to hold weekly lectures in the parish schoolhouse.—*Irish Ecclesiastical Gazette.*

Proposed Tramways in Dublin.—This project is not likely—and very properly so—to find much favour here. The corporation originally opposed a "private bill" for this purpose, the Rathmines Commissioners set their faces against it *in toto*, and the disfavour of the citizens generally is pretty manifest. The principle may have its advantages in mining, coal, or quarry districts, on country roads, and in suburbs of cities; but it will not be favourably regarded in crowded thoroughfares, especially in the streets of our metropolis.

Good News for Stone Masons.—"We have just seen in operation," says the *Journal de l'Aisne*, "an ingenious machine for cutting stones, invented by a clockmaker of Fessieux, M. Jean Marie. This machine hews, scapples, and carves the hardest stones with remarkable precision. The bed on which the stone to be worked is laid runs on iron rails, backwards and forwards, as may be required. We saw it hollowing out, although it was very hard stone, a job which would occupy a man three or four days, but which was scarcely an hour's work for the machine."

NOTICE.

Post-office Orders and Remittances should be made payable to Mr. Peter Roe, 42, Mabbot-street, Dublin

☞ *NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the* Dublin Builder." *All other Communications should be addressed to the "Proprietor and Editor,"* 17, Lower Gardiner-street.

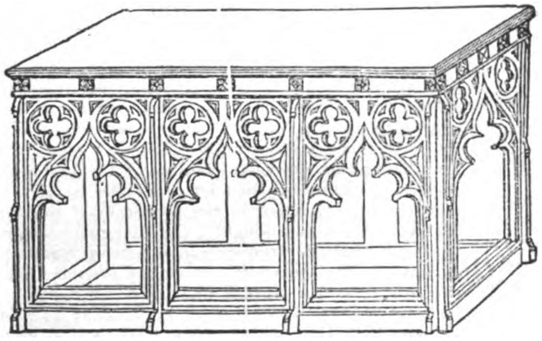
TO BUILDERS, DECORATORS, CONTRACTORS, ETC.

Genuine White Lead, best manufactured Zinc Paint. Pure Raw, Boiled, and Refined Linseed Oils. Fine American Turps Rosin, Pitch, and Stockholm Tar. Ground Paints of all colors, Patent Dryers, Red Lead and Putty. Gold Size, Torch Oil, Coal Tar. Black, Red, Pine, Oak, and Copal Varnishes. Unadulterated Colza, Petroleum, Phenola, Photogen, and all Lamp Oils. Superior Olive, Lard, and Sperm Oils, for engine use. White and colored Cotton Waste. Best Glue, Russian Tallow, Cart Grease. Paints to any color, mixed ready for use, in small and large quantities, to order, well adapted for the country and exportation. Export orders promptly executed, with goods of *best quality*.

GEORGE SPILL, OIL AND COLOR MERCHANT,
65, 66, & 67, ST. GEORGE'S STREET, LONDON DOCKS.

WILLIAM BISSELL,
UNION STREET, WOLVERHAMPTON,

SOLE Proprietor of the Improved MORTISING MACHINE, the newest, most easy, simple, and powerful, yet invented. Also the universally and justly-celebrated Equi action RIM and MORTISE LOCKS.
Patentee of the well-known Flooring Dogs, and 4-Ton Lifting Sacks.
Factor and General Manufacturer of Builders' Ironmongery.



(Executed for Grangegorman Church.)

JOSEPH DIGGES,
ECCLESIASTICAL UPHOLSTERER,
AND
Manufacturer of Church Furniture and Appointments.

COMMUNION TABLES, CHAIRS, LECTERNS, KNEELING STOOLS, BENCHES, ETC.,
In Plain or Carved Woods.
ALTAR CLOTHS, TABLE COVERS, CHANCEL CARPETS, CUSHIONS, AND PULPIT DRAPERIES,
All made to order, with good taste and economy.

Blinds to suit every description of Church Windows. Architects and others can depend on having their Designs carefully carried out.

27, LINCOLN-PLACE, DUBLIN.
(Opposite the Turkish Baths.)

WATSON'S PATENT SELF-ACTING VENTILATOR.

VENTILATION WITHOUT VIOLENT DRAUGHT.

THE SIPHON PATENT VENTILATOR is to be had only of CHARLES WATSON, F.R.S.A., &c., the Patentee, at his Works, KING'S CROSS, HALIFAX, YORKSHIRE, and of

JAMES W. GATHERAL, 93, VIRGINIA-STREET, GLASGOW.

SIX THOUSAND of these Ventilators have been successfully applied to Churches, Schools, Factories, Dwelling-houses, Stables, Stores, Workshops, Warehouses, & Farm Buildings.

NOTICE.

Subscribers who have preserved their copies for 1859, are informed that they can have a Wrapper and Index by remitting Four Stamps to the Publisher, or the Vol. complete for 3s. 6d., or 4s. 6d. per post.

Advertisers in London will please take notice, that the authorised local Collector of Accounts *is* Mr. William H. Sterling, 24, *Charrington-street, St. Pancras.*

SCIENCE & ART DEPARTMENT,
MUSEUM OF IRISH INDUSTRY,
STEPHEN'S GREEN, EAST.

Government School of Science, applied to Mining and the Arts.

A Systematic Course of *Thirty Lectures* on "*Chemistry*, and its application to the Arts," by William K. Sullivan, Ph. D., M R.I.A., will be commenced in the Theatre of the Museum of Irish Industry, on Tuesday, February 14, at Four o'Clock p.m., and be continued at the same place and hour on every day of the week, except Saturday, until the course be completed.

For the above course of *Thirty Lectures*, a *Fee* of 3s. 6d will be charged.

Copies of the Programme of Educational Arrangements for the Session of 1859-60, may be obtained on on application at the Museum of Irish Industry, Stephen's-green East.—By Order,

GEORGE PENNY, Clerk to the Museum.
Museum of Irish Industry,
January 30, 1860.

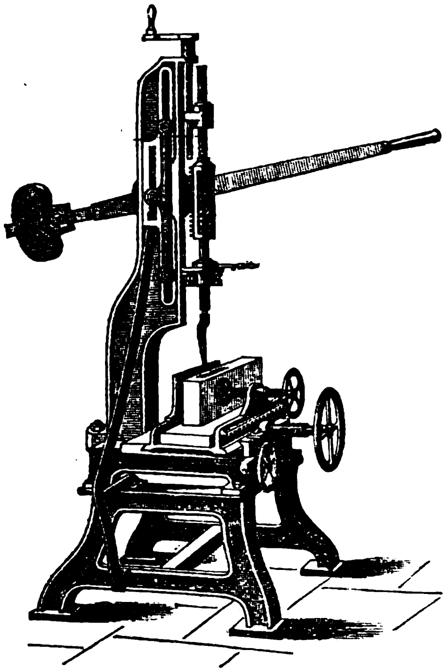
THE STATIONERS' COMPANY'S SHEET ALMANAC for 1860, price 2s. on a large royal sheet, equally adapted for the counting-house and the library, is embellished with a beautiful view of the proposed ATLANTIC HARBOUR at GALWAY BAY, from a drawing by Phillips, of which plate proof impressions may be had at 3s. each, as well as of the plates of preceding years.

Published by the Stationers' Company, at their Hall, Ludgate-street; and may be had of all Booksellers and Stationers.

WM. M'CLEARY WIGHTMAN,
PRINTSELLER ARTISTS' COLORMAN,
22, *NASSAU-STREET.*

Has always on hand a large and varied Stock of Drawing Materials, Paper of different sizes, Colors Brushes, Pencils, &c., which professional gentlemen and others will find adapted to their requirements, & moderate in price.

Artists' Warehouse and Photographic Gallery,
22, NASSAU-STREET.



JOHN CLARK'S

MORTISING MACHINE

(GREEN AND JACKSON'S PATENT).

MAY be seen at work with Messrs. Cockburn, Crowe, Meade, Moyers, Kelly, Geraty, Kennedy, T. H. Carroll, J. H. Carroll, Roberts, Bolton, G. Farrell, R. Farrell, Douglas, Hughes, Alford, Rooney, Builders, DUBLIN; Messrs. Rogerson, Dawson, & Russell, Railway Carriage Manufactory, Atlas Works, Dublin; Great Southern and Western Railway Co.'s Works, Inchicore; at BELFAST, with Messrs. Fulton, Carlisle, Lowry, M'Creary, Kent, M'Cracken; at CORK, with Messrs. Hill, Evans, Joyce; at LONDONDERRY, with Messrs Boyd, Brothers. Testimonials from all parts of the United Kingdom.

JOHN CLARK, JUN., Manufacturer of Self-acting Circular and Upright Saw Benches, for

SAWING, TENONING, GROOVING,
RABETTING, BORING WOOD,

Punching, Drilling, and Countersinking Slates.

OFFICE, No. 12, CALL-LANE,
LEEDS.

IMPORTANT—THE ONLY MANUFACTORY OF OIL-CLOTH IN IRELAND!!!

61 & 62, GREAT STRAND-STREET, DUBLIN,

Entrance, 69, JERVIS-STREET. Established 1791.

JOHN D. FRANKLIN, PROPRIETOR.

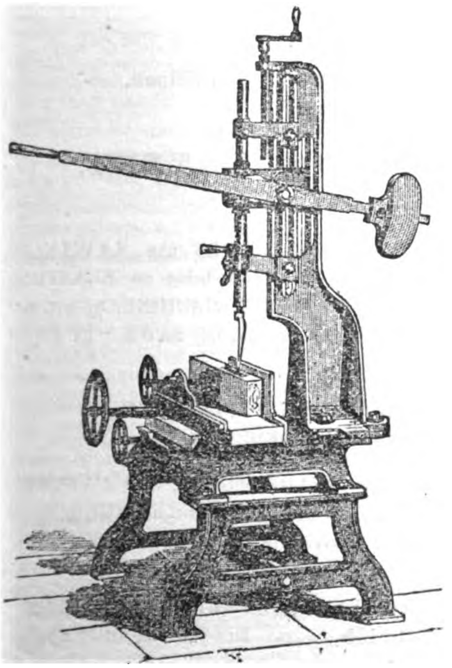
J. D. F. invites the Public to see the Floor-cloth making, which cannot be seen in this country unless at his Factory.

HOUSE PAINTING, DECORATING, &c., carried on as usual in the same superior style, with that economy and despatch for which FRANKLIN'S Establishment has been celebrated for the last Sixty Years J. D. F. begs to inform the Nobility and Gentry that he has been so fortunate as to secure the entire services of two of the first GRAINERS and Ornamental PAINTERS, LETTERERS, &c., in Ireland, and can with confidence undertake the most superior class of work, in addition to the plainest description.

N.B.—A carefully-selected Stock of Room Papers, Decorations, &c., suitable for all description of rooms, at prices not known before. Workmen sent to all parts of the country.

GALLON AND BEAN, LEEDS,

Cut & Wrought Nail Manufacturers, & Hardware Merchants,



RESPECTFULLY request all BUILDERS, CONTRACTORS, CARPENTERS, &c., requiring Mortising Machines, previous to purchasing, to examine and test *their patent combined Crank and Lever Machine*, which will Mortise (Tenon and Bore, if required) both Hard and Soft Wood, and is also adapted for Drilling and Punching Iron.

The superiority of this Machine over *all* others consists *in the substitution of a solid wrought-iron plate Crank or Eccentric, by which greater power is obtained, in place of cast-metal Rack and Pinion Wheel, the Teeth or Cogs in which are so liable to strip or break out*—in the direct and perpendicular action of the Lever and Crank on the Cutting Tool, and consequent diminution of friction--in being *stronger* and *less complicated* in its construction, and more *powerful* in its motion—in the *facility* of its *adaptation* to the various depths of material —and in its *non-liability to break* or get out of working order.

This Machine has now been adopted in preference to *all others* by some of the principal Builders in London, Glasgow, Edinburgh, Dublin, and Belfast, who will bear testimony to its being the most powerful and efficient yet made

For further particulars apply to the Patentees and Makers, GALLON, BEAN, and LUMB, LEEDS.

Extract from the Report of the Royal Dublin Society's Spring Show, 1859:—

"Gallon, Bean, and Lumb, Leeds, exhibited a very useful and complete Mortising Machine, which was highly commended."

N.B.—The Patentees respectfully intimate that this Patent extends to, and comprises Machines for Mortising by Steam and other motive power, as well as by hand: and makers and vendors of, or parties buying or using Mortising Machines, *are cautioned against any infringement*, as the patent right will be strictly maintained.

CONTRACT FOR WORKS.

THE Directors of the DUBLIN and WICKLOW RAILWAY COMPANY are ready to receive Tenders for the Construction of the First division of their Extension Railway from WICKLOW to GOREY, under the Company's act of 1859, according to Plans and Specification of their Engineer, W. R. LeFanu. This division extends from Wicklow to Tigroney West, 14 miles or thereabouts; the contract to include all works, except Stations; the Company finding Iron and Timber for the permanent way.

The Plans and Specification may be seen, and any further information obtained, on application to the Company's engineer, 59, Fitzwilliam-square, North, Dublin.

Tenders, on forms to be had at Mr. LeFanu's Office, to be addressed to the Secretary, 48, Westland-row, Dublin, and marked "Tender," will be received up to Thursday, 29th March, 1860, inclusive, to which date the time for reception of Tenders has been extended. A. MOORE, Secretary.

16th February, 1860.

Auctions, Sales, &c.

AUCTION OF WOOD GOODS.

JOHN MARTIN AND SON
WILL OFFER BY AUCTION,
ON THURSDAY, 1st *MARCH*, 1860,
AT THEIR STORES, NORTH WALL,

The following Goods:—

The entire cargo of Spruce Deals, per Ganges, from St. John's containing

16,500 Pieces of Deals, and
2,800 „ of 1st quality Spruce, per Hector, from Quebec.
2,400 „ 2d do do do do.
60 „ large sized St. John's Pine (now landing)
500 Tons Crown Memel.
300 „ of Red Pine.
500 „ large sized Quebec Pine.
60 „ Quebec Oak.
124 Pieces of Birch.
60 „ Ash.

And if arrived in time, the cargo of Spruce Deals, per Empire Queen, from St. John's. Sale to commence at half-past Twelve o'clock.

JAFFRAY BARCROFT, Broker and Measurer.
North-wall, Dublin, 4th Feb. 1860.

FOR SALE, at the WATERFORD SHIP YARD, Ferrybank, a very superior highly finished NEW STEAM ENGINE,

Estimated at about 40 Horse Combined Power, which highly improved construction is admitted to be the most economical in the consumption of Fuel. Condensing Cylinder, 21 inches diameter, with 5 feet stroke. High Pressure Cylinder, 18½ inches diameter, with 2½ feet stroke.

This Engine has been built with the best materials and workmanship, regardless of expense, and is particularly well adapted for a Flour (or other) Mill. The very great falling off of late years in the supply of water-power renders it almost indispensable that auxiliary steam power should be attached to Flour Mills to ensure constant working of the establishment during the period of scarcity of water.

Further particulars can be had by application at the Ship Yard.

CHURCH FURNITURE, &c., ALTAR and COMMUNION CLOTHS, ECCLESIASTICAL CARPETS, ROBES, and every article for sacred use, at moderate prices.

Messrs. HARRISON and Co., *Church Furnishers and Robe Makers to the Peers, Bishops, Judges, &c.*, 54, CHANCERY-LANE, LONDON.

DRAUGHTS of COLD AIR round DOORS and WINDOWS prevented by GREENWOOD'S PATENT INDIA RUBBER STOPS, and Self-acting Slides, for the bottoms of Doors, which have proved to supersede all previous invention for the purpose of Making the Joints of Doors, Windows, Show Cases, &c., AIR TIGHT.

Agents for the Patentee—
FERGUSON AND CO.,
Patentees & Manufacturers of Vulcanized India Rubber, Gutta Percha Waterproof & Airproof Fabrics,
108, GRAFTON-ST., DUBLIN.

ROGERS'S PATENT PEAT CHARCOAL, for Sanitary Uses generally: for Disinfection of the Dead, Purification of Sick Chambers, Filtration of Water, Purification of Ships, Stables, Cattle Sheds; for Packing Provisions, Eggs, Butter, &c.; and for Agricultural Purposes. Manufactured by THE HEALTH OF TOWNS IMPROVEMENT COMPANY.

Works and Depots:—Derrymullen, Robertstown, Co. Kildare; Newcomen-bridge, Dublin; 5, Donegal-square, North, Belfast. General Agent—JOSIAH G. THOMPSON.

Thomas Brawn Manufacturer of

ECCLESIASTICAL AND DOMESTIC MEDIÆVAL

METAL WORK,

IN SILVER, BRASS, AND WROUGHT IRON;

Sacred Vessels, **Memorial Brasses, Metal Screens, Altar Rails and Gates, Hinges, Handles, &c.**

METAL READING DESKS, LECTERNS,

Pulpit Lights, **Coronae, Chandeliers, and Standards for Gas and Candles,**

SPIRE AND GABLE CROSSES,

And every description of GAS FITTINGS—Candlesticks, Lamps, Branches, and Branch Candlesticks, &c.

T. B. begs to inform the Clergy, Nobility, and Architects in general, that he has been practically engaged for upwards of 14 Years in the Execution and Manufacture of Mediæval Metal Work, from Drawings of the most eminent Architects.

107, BARR-STREET, GREAT HAMPTON-STREET, BIRMINGHAM.

Magic Horse Taming Nose Pinchers (Geyelin's Patent),

Warranted to subdue the most vicious horse at the instant. Kicking, rearing, plunging, and running away rendered impossible. Sold only by W. H. KENNEDY, Agent, 462, Oxford-street, London, W.C. Price £1 1s. each.

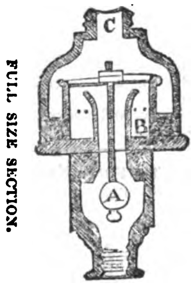
The Universal Gas Burners' Regulator (Geyelin's Patent),

The only one in the world by which the flame from Argand, Fish-tail, and all other burners remains invariable under all variations of pressure, and the cost of each light is less than One Farthing per hour.

Can be fixed horizontal, close to, or distant from the burner; is ornamental—simple in construction, consisting of a double chamber, the inner perforated, covered with a diaphragm giving action to a spherical valve.

Price 3s. each. One sent on receipt of 3s. 6d. in postage stamps.

W. H. KENNEDY, Agent, 462, OXFORD-STREET, LONDON, W.C.



REGULATOR.

Patent Endless Brick, Tile, and Socket Pipe Machine,

The most perfect, compact, and portable ever invented.

Sold by W. H. KENNEDY, Agent, 462, OXFORD-STREET, LONDON, W.C.

The Hygienic Spring Laths Bedstead (Geyelin's Patent),

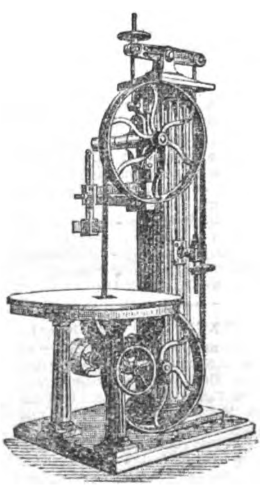
Combining the advantages of Metallic Bedsteads with the comfort of a Spring Mattrass, at less than half the cost. Certified by medical men as the best and most comfortable bedstead ever invented; invaluable for hot climates; cannot possibly harbour vermin. Sold by W. H. KENNEDY, Agent, 462 Oxford-st. London, W.C.

POWIS, JAMES, AND CO.,

Engineers, Patentees, and Manufacturers of all kinds of Machinery for working in Wood.

VICTORIA WORKS, BLACKFRIARS, LONDON.

ENDLESS BAND SAWING MACHINES, NEW PATENT.



NO MORE BREAKAGE OF SAWS.

POWIS, JAMES, AND CO., beg to call the attention of all who use SAWING MACHINERY to their NEW PATENT, dated August, 24, 1858, being an ELASTIC COMPOUND ADJUSTING LEVER MOTION ENDLESS BAND SAWING MACHINE, by which the STRAIN upon the SAW USED is so REGULATED that BREAKAGE OF SAWS "IS ENTIRELY DONE AWAY WITH."

ONE OF THESE MACHINES, UPON A LARGE SCALE, IN FULL WORK,
AT HER MAJESTY'S DOCKYARD, DEPTFORD.

A STOCK OF MACHINERY FOR WOOD ALWAYS kept READY, including their PATENT MACHINE for MORTISING, TENON-CUTTING, and BORING, of which upwards of a THOUSAND have been sold in ENGLAND ALONE, and is the ONLY MACHINE which is SELF FEEDING, and doing the THREE KINDS of WORK by ONE MACHINE.

One of these MACHINES to be seen at Work at Mr. MAURICE BROOKS', Wholesale Builders' Ironmongery Stores, SACKVILLE-PLACE, DUBLIN, Agent for Sale for the whole of Ireland.

The Dublin Builder.

VOL. II.—No. 16.

THE ULSTER HALL (BELFAST) COMPANY'S RECENT COMPETITION.

WE have over and over again in this journal expressed our opinion that there is no word in the English language referring to architectural matters more perverted than "Competition," that as conducted in these countries it is a mere myth, an *ignis fatuus* at which all *may* grasp, but none but the charmed few *can* clutch. Each succeeding month strengthens our opinion, and hosts of communications—quite too numerous for publication—reach us from all quarters disclosing some new "mystery," stating some fresh "cause of complaint" against committees for breach of faith, &c., and from some of these forwarded to us recently, relative to a matter at home, we, in another portion of this current number, insert a collection. It seems, however, that our northern friends occasionally distinguish themselves in such a manner as to provoke censure likewise, and though we but recently felt pleasure both in announcing a proposed "competition" for the new Ulster Hall in Belfast, and the decision in favour of a talented and rising member of the profession resident in the district, yet our attention is directed in no very flattering manner to the subsequent doings of the committee. This worthy body met on this day week when, as we are informed, various supplemental plans for a hall were taken into consideration—viz., oblong, circular, horseshoe, &c. Mr. Corry, who said he was *not* a professional man, submitted a plan of an octagonal hall, which was referred, with others to the committee. It was also agreed to make an increase of £10,000 to the capital of the company. We have already urged on this company the propriety of erecting a hall in Belfast which shall meet the requirements not only of the present but of the future, looking forward to the *certain* extensive increase of the town in numbers, wealth, and musical taste. With regard to the proper shape of the hall, to obtain all the requisite acoustic properties, we presume the committee should be guided by the experience of their architect—a gentleman whose professional antecedents proclaim his competency—and by the examples of such plan already built, either for imitation or avoidance. One paragraph of the instructions to architects in reference to the competition is as follows:—

> "As the hall is especially intended for musical purposes, its acoustic properties are of the highest importance, and it is therefore desirable that there should neither be great projections nor deep recesses, but that for decoration colour should be to a great extent relied on."

We are ignorant of the motives which led the committee to adjudge a prize to any of the competing architects; but, surely, one essential element, where a plan was required for a hall intended especially for musical purposes with acoustic properties necessarily of the highest, was their having the design of a hall placed before them possessing those acoustic properties; and, if so, why is it that the shape and proportions of a musical hall, with "acoustic properties," appears to *be yet a matter of search* to the committee, as well as the shareholders? Are we to presume that the £50 and £25 given, or rather offered, as prizes, have been as yet unproductive? From one of the paragraphs already quoted, which says,

> "No prize to be paid until the directors are satisfied that they can effect a contract for the execution of the work at the price estimated by the architect of the design selected,"

we think it not improbable that this clause will save the money-prizes from being paid away. A previous clause limits the total expenditure to £7,000, and we have heard that the lowest tenders were more than double that sum.

Such a proceeding by a committee would seem first, "after careful consideration, no doubt," to proclaim the right of a certain professional man to priority over his fellows, and then, by tampering with his suggestions, to ignore their own capacity of judgment and question his competency, A reference to a properly qualified architect, of all the designs submitted in competition, with a view of abiding by his decision, would have been, to say the least, the most judicious course for a committee to pursue who seem to be mentally straitened, rather than adopt their own ideas, and, through timidity of purpose, subsequently seeking other advice outside the pale of the profession, cast a slight on their own choice. Reviewing this and other proceedings, we must exclaim, that "the path of competition—like true love—never runs smooth."

NOTES ON THE ROUND TOWER CONTROVERSY.[*]

THE names by which the Round Towers of Ireland are locally known has not received that attention and investigation which the subject deserves; not that I would expect to arrive at very decisive results, as affecting the question at issue in this still undecided controversy. I have always endeavoured, however, when possible, in examining these structures, to ascertain the names by which they are known to the Irish-speaking people of the neighbourhood. In the south and west of Ireland, where the ancient language is still generally spoken among the peasantry, this is not difficult to ascertain, especially if the inquirer knows how to go about, as with strangers a little diplomacy is sometimes requisite to gain the confidence of the people. The first answer I generally receive to my question of "What do you call that building?" is, "Wisha then, sure isn't it the steeple of Cloyne;" or, "Sure, your honour, they call it the big steeple of Ratto;" but when I followed up the inquiry by asking them what they called it in Irish, I soon found out it had its peculiar and distinctive name in that language.

As far as my inquiries have gone, then, I find that our Towers are known by *three* distinct Irish appellations—namely, *Clugaugh*; *Clugaus*, or *Clochais;* and *Giolcach*, or *Quilcach*. I have written the names as they are pronounced.

Dr. Petrie considers that the first of these appellations is the *Clochteach* or *Cloichteach*, of the Irish annals, and that it means a round tower belfry; that wherever it is met with it should be so translated; and that all notices where the word occurs refer to our Round Towers, and that, consequently, they fix the age and use of these structures. This learned writer has devoted a considerable space in his work "On the Ancient Architecture of Ireland" to this branch of his subject. He has treated it with great ingenuity, and has given it such a manifest importance that the reader cannot fail to recognize the fact that it is at once the foundation and cap-stone of the structure he has laboured to rear. Most readers on the subject are aware that the Round Tower controversy has been narrowed by two theories, the Christian and pre-Christian. Dr. Petrie has ably and ingeniously advocated the first theory in his work, which is an invaluable contribution to our knowledge of the early architecture of Ireland, but in my opinion a failure as regards the theory he supports. Many seem to think that the high standing the author has deservedly attained in the archæological world is quite a sufficient warrant for the correctness of the statements and opinions put forward: but this I hold as not sound discretion. If we are to be carried away by the *prestige* of names, by far the greatest amount of Irish antiquarian learning and research has been on the other side. The Christian theory found advocates in Lynch, Ledwich, and Molyneux, who advocated their Danish origin (the Danes being Pagans), as also Harris, Milner, Smith, Sir R. C. Hoare, Bell, Wilkinson, and finally Petrie. Of these Milner and Hoare had no knowledge of Irish antiquities. Bell and Wilkinson's treatises are purely descriptive.

On the side of Pagan antiquity are, Vallancey, editor of the "Collectanea de Rebus Hibernicis"; Dr. Lanigan, author of the "Ecclesiastical History of Ireland"; Dr O'Conor, the learned librarian of Stowe, and editor of the "Hibernicarum Scriptores Veteres"; Sir William Betham, author of the "Etruria Celtica"; "the Gael and Cimbri," &c.; Beaufort, Dalton, O'Brien, Moore, and Windele, all deeply versed in the literature, language, and monumental antiquities of the country. To these I could add the names of many who have made the Irish language and antiquities the study of their lives, but who have not come before the public as authors.

The earnest inquirer, however, will not be carried away by the mere pretensions of individual learning, however well founded; but will patiently investigate all sides of the subject, examine the buildings themselves in all their details and analogies, compare the peculiarities of their construction, and their architectural features with those of similar erections in other countries. He must study the language, religion, and customs of the people amongst whom they are found, and the traditions connected with them, the known history of the people, their origin and migrations. Such a mode of investigation is requisite, in order to form sound opinions upon the subject before us, and is obviously the only mode, in the absence of all *historical evidence* as to their origin and uses; and I fearlessly assert, that up to the present time, we have no such evidence whatsoever as to the erection of a single *round tower* in Ireland.

---

[*] By Richard Rolt Brash. From the "Ulster Journal of Archæology."

I proceed now to advert to the several local names applied to these mysterious buildings.

1. *Clugaugh.*—This term, as a local designation for a round tower, is very rarely used. The only instance I have been able to ascertain of its application is to the tower of Fartagh, county Kilkenny, which is called *Clugach-na-Feartagh.* Mr. John Windele, of Cork, who has made a personal examination of all our southern Round Towers, informs me it is the only instance he has met with of its use. This word may be derived from some of the following sources:—

Clogad, a helmet. [O'Brien's Dict.] The ancient Irish helmet was conical, and bore no inapt resemblance to the conical covering of the towers.

Clogad, *Clogaide*, a helmet, a cone, a pyramid. [Dictionary of the Scottish-Gaelic language.]

Clogad, a helmet. [O'Reilly's Irish Dictionary.]

Clogad, a cone, a pcramid. [ibid.]

It will require no stretch of imagination, or straining of the etymologies to make application of the above. Again we have—

Clogachd, a belfry. [O'Reilly's Dictionary.]

Clogachd, a belfry. [Gaelic Dictionary.]

It is curious that the more ancient dictionary of O'Brien has not that word; and O'Reilly has taken it from Shaw's Gaelic Dictionary.

2. *Clugaus*, *Clochais.*—The term *Clugaus*, *Clochas* or *Clochfas* is locally applied to a great many of our Round Towers, as—Dysert O'Dea, county Clare; Kilmaoduagh, county Galway; Clonmacnois, King's County.

At the latter place, where there are two towers in existence, they are respectively called *Clochaus Mor* and *Clochaus Beg.* O'Brien's Dictionary gives us *Clogas*, *i.e.* *Clog-cas*, a belfry or steeple; O'Reilly, *Clogas*, *Clogchas*, a belfry.

Mr. Windele has suggested to me the derivation of this name from *Cloch*, a stone, and *fas* growth; "the growth of stones," in allusion to the superstitious traditions so prevalent concerning Round Towers, of their being built in one night: thence termed in the Irish language familiarly *Fas-non-oidhche*, "the growth of one night." This tradition respecting business of great antiquity, or whose origin is involved in obscurity, is prevalent all through the East, and particularly in China.

Another derivation suggests itself from *Cloch*, a stone; *fas*, hollow, vacant [see O'Reilly, also M'Leod and Dewar's Gaelic Dictionary]; "the hollow stone," a term peculiarly expressive of the nature of the building.

But another suggests itself to me of more force and probability than any of the preceding, and one the earnest consideration of which I would recommend to those more competent to analyze these etymologies than I am—namely, from *Cloch-ais*, the stone of death: *Aise*, death. [O'Reilly's Dictionary.] *Aise*, death, applied to a dead person; a shroud. O'Brien's Irish Dictionary.] It may be strange to some that a tower should be called a "stone," but this is a figurative mode of expression very usual among the Irish. Thus, we have near Macroom, county Cork, a mediæval castle called *Clach-Dhaibhi*, or "David's stone," from the builder's name; another, in the same county, is called *Cloch-Philip*, at page 2174 of the "Annals of the Four Masters" (O'Donovan's translation) we have also the Knight of Glynn's castle, on the Shannon, called *Cloch*-Gleanna; and again we have the oratory of the recluse called *Cloch-ancoire*, "the stone of the Anchorite." Amongst the Highlanders, to the present day, it is customary to intimate going to church by the expression, going to the *Clochan.*

But some may ask why should a Round Tower be called *Cloch-aise*, "the stone," or "pillar of death"? My answer would be, because the pillar towers of Ireland are *monumental* and *sepulchral.* I cannot now go into all the facts and arguments which suggest themselves in support of this theory, but would briefly state my reasons for holding this opinion. It has been the custom in the remotest ages, and amongst the rudest tribes, to set up some object to mark the resting-place of the distinguished dead, or to commemorate some remarkable event: thus, the pillar-stone became the prevailing monument of uncivilized nations, and was sometimes erected of a height that almost rivalled the masonry-built towers of more polished nations. All the megalithic monuments ascribed to the Celts are still found among the Khasia mountaineers, in Northern India; amongst which are pillar-stones 30 feet in height, standing by *Cromlechs*, and marking the graves of their deceased friends. [See Hooker's "Himalaya Journal."] At Carnac, in Brittany, exist pillar-stones 40 feet in height. [See Deane's "Worship of the Serpent."] In our own country pillar-stones from 15 to 20 feet in height are not uncommon. The monumental pillar-towers of the Chinese go back to a date of near 1,000 years before our era. The Buddhist Minar, and the Jain towers of India are of a similar class. The Romans likewise adopted the hollow pillar, both for sepulchral and monumental purposes. On a tumulus at Cocumella, in Etruria, is a sepulchral Round Tower. Remains of conical towers surmount the tomb of Aruns, at Albano. The *hollow column* of Trajan was erected by Apollodorus, for a tomb, and as a memorial of his victories. The column of Antonius Pius was erected by Marcus Aurelius in memory of that emperor. There are numbers of circular tower sepulchres at Palmyra; and in Armenia the ancient form of sepulchre was a low circular tower, with a dome-shaped covering. We, too, in our day, have followed the prevailing fashion of antiquity: our cities and towns present numerous examples of pillar towers, which, though not sepulchral, are monumental and commemorative. And it is a curious and suggestive fact, that national instinct so far overcame prejudice and theory, that a pillar-tower after the veritable ancient Celtic type has been erected to perpetuate the memory of Daniel O'Connell, in the cemetery at Glasnevin, near Dublin.

That the ancient Irish, in the progress of civilization, should be led to relinquish the lofty, unshapen, and ponderous pillar-stone for the more symmetrical and aspiring hollow column, is but natural; and that they erected these columns, at least many of them, for sepulchral uses is certain, if stubborn facts are to be relied on.

The South Munster Society of Antiquaries were the first who turned their attention to the sepulchral character of our towers. The idea, I believe, originated with Mr. John Windele, of Cork: in the year 1841 they explored the towers of Cloyne, Ardmore, Kinneigh, Cashel, and Ardpatrick. In Ardmore and Cloyne they found human remains, placed in the basement of the towers, under circumstances indicating great care and forethought. Cashel and Ardpatrick were found to have been previously ransacked, as was proved by indubitable evidences.

Some gentlemen of Ulster also took up this interesting subject, and made explorations within the basements of most of the towers in that province: the result of their labours has been published in the *Ulster Journal of Archæology*; from which we find that human remains, deposited under similar circumstances, and with evident care, were found in the Round Towers of Clones, Maghera, Armoy, Drumbo, Drumlane, and Inniskeen. The exploration of Antrim tower was imperfect; at Ram's Island, the usual concrete floor, generally found protecting the remains, was found broken through, corroborating a previous statement made by Mr. Windele, of Cork, that human remains had been at one time found there. At Nendrum no discovery was made; at Devenish there was also no result; at Tory Island merely a portion of a sepulchral urn was found. Sir William Betham states that Dr. John Leslie, Bishop of Raphoe, removed a Round Tower which formerly existed there, and discovered the bones of a man under it. Human remains were also found at Roscrea tower. At Timahoe such relics were also found, and a sepulchral urn.

Dr. Small, in his account of the Round Tower at Abernethy, Scotland, states that the ancient tradition of the place was, that the Tower was erected as a mausoleum for the Pictish kings: to verify, or rather to test the tradition, the Tower was excavated, and several skeletons were found therein. I remember well that, on visiting Abernethy myself, the aged sexton who assisted me in measuring it, stated, in answer to my enquiries respecting the traditions, that the old people informed him it was built by the *Peghts* as a burial place for their kings; in confirmation of which he pointed to the remains of the palace of the kings of the *Peghts*—a mighty ruined *Dun* on a prominent spur of the Ochill hills, and about half a mile from the Tower.

The scope of the present paper will not permit me to follow up these investigations. I have barely touched upon the reasons that have induced me to give my attention to the sepulchral and monumental character of these unique structures, and I submit that they are of a nature deserving of serious consideration. Should this theory be the correct one, the derivation of the term *Cloch-ais*, *Cloch-as*, or *Clogas*, would no longer be doubtful as the "Stone (tower) of Death."

3. *Giolcach.*—Among the towers locally called *Giolcach*, or as it is pronounced, *Quilcach*, and sometimes *Kilcach*, we have—Ardmore, county Waterford; Kinneigh, county Cork; Cloyne, county Cork; Ratto, county Kerry; Ardpatrick, county Limerick.

With reference to the Tower at Ratto, Dr Petrie says [page 397] it is now popularly known by the name *Giolcach*, by which *is understood a Bell-house*, and which is *obviously a local corruption of Cloighteach, or Cloichteach.* Now I beg to state that

I lived two months in the neighbourhood of Ratto, and that there is not in Ireland a locality where the Irish language is better spoken and understood. The local people do not understand the word *Giolcach* to mean a Bell-house; they would be astonished at the Doctor's convenient assumption if they heard of it; and it is not so found in any Irish dictionary; neither is it a local corruption of *Cloigteach*, as the people there know the meaning of the term perfectly well, and have very truthfully applied it. By reference to O'Reilly, we find *Giolcach*, "a reed, cane, broom; a place where reeds or canes grow." Now, any one who knows the locality of Ratto will remember that it stands about a furlong from the river Brick; and that the river, with the extensive marshes which bound it, and the banks of a canal running from the river up to the tower, are prolific of those enormous *reeds* with tufted tops, called in Irish *Giolcach*. What, then, can be more natural, than that a highly imaginative and poetical people like the Irish, should call their lofty, slender, graceful towers from those elegant and tapering reeds, which, with their tufted conical tops, offer so striking a similitude. How numerous are the instances of such appropriations in our topographic nomenclature. Besides its application to some of our towers, we find this word used in many places as a topographical designation. In the county of Waterford we have a parish called *Guilcach;* in the county of Cavan is the celebrated hill of *Cuilcagh*, of which so many legends are current, and which was the Mount of Inauguration of the Maguires; there is also another locality near Bailieborough called *Quilcagh*. These instances show that the term is a well-known and properly applied designation, and not a corruption of *Cloigteach*, as Dr. Petrie would lead us to suppose.

(To be continued.)

LAW NOTES—BUILDING QUESTIONS.

COURT OF COMMON PLEAS.

Continued from page 210.

Kempston v. *Butler*.—Mr. Timothy Murphy,[*] builder, of over 30 years' experience—Saw the manner in which the houses 82 and 84 were braced; considered the struts too light; knew the custom always in Dublin for contractors making alterations to protect houses adjoining; on cross-examination, stated he never was in the house or examined it.

John Sterling Butler,[*] architect.—Considered the pieces used for struts insufficient, and the absence of a brace in the street a great omission; proved the accuracy of the model of the house after the fall (having examined the premises in company with Messrs. Louch and Donnelly), showing the bressumer and uprights in front, also the bressumer, metal pillar, and story-post adjoining No. 81, which were as firm as the day they were set. Cross-examined by Mr. Fitzgibbon—if the front of the house and bressumer had been braced, and a sufficient number of proper pieces used for horizontal struts, the house could have been maintained; if there was an offset on the old foundation, and the new wall built on same, it would have the effect of raising the flagging in the kitchens of 82.

The following witnesses were produced on behalf of the defendant:—

Mr. John Butler, the defendant, testified to being an architect and builder of considerable experience—stated that the front wall of 83 overhung very much, it might have fallen in a moment or last for one year; the front wall required rebuilding; the angle chimney-stack was built against 84, and quite unconnected therewith from the foundation to outside of roof. The shop, the upper staircase, and garret divisional wall between 82 and 83 were plastered; the drawing room and attic were wainscotted; first saw plaintiff in company with Hipwell the day or day after commencing work, on the 17th November, 1858; plaintiff, Hipwell, and defendant went up to the top rooms of 83, and spoke together as to the propriety—and advised Hipwell, who consented—of taking down the top of his high chimneys; defendant had it done within an hour. When the roof and walls, chimney, &c., were down to top story floor set first range of stays; cracks appeared below gutter in flank of 82, about half an inch wide, an old crack (sketch produced, made in March following). The next story removed, three more cracks were discovered; 50 cracks—probably 100 nearer the mark; on attic floor another range of stays set; next story (first floor), removed another range. Plaintiff at this stage brought in defendant to examine 82, and pointed out separation between floor and wall in garret and attic stories. Defendant remarked, if nothing worse than that occured plaintiff had little to fear; heard no further complaint until after 83 was removed; weather continued stormy and wet from this time up to the fall, knew nothing about 82 house, flank wall in dilapidation, bricks loose; at 35 feet from rere of 88, 8 feet of division wall were underpinned 2 feet deep; commenced new building in the rere 40 feet from rere wall; cleared entire surface 2 feet deeper than old kitchen of 83; old foundation of 82 flank deeper by 7 inches than new foundation; 82 house so bad that the public officer should have condemned it; a party wall is half and half on each land; in 1767 the house 83 was leased (lease produced)—26 feet front, 26 rere, and 130 from front to rere. In 1834, 82 was refronted; no notice required on adjoining parties to take down their own house. Defendant produced contract (dated 16th October, 1858,)—to take down 83, stack the bricks, stay and shore up adjoining house, for £120—with Mr. Ferguson, the owner; commenced this contract on 17th November, and completed it on 11th December, '58. On 23rd November contracted with Falkner to build a house on the site of 83 for £1148, and commenced to clear for foundations on 12th December, and to build on 30th of same month following. Plaintiff brought defendant on Monday week before 82 fell, to the top room, and the flank was cracked one inch at the rere; old cracks showed very much; examined the house generally, and the old cracks in shop also showed very much; remarked to plaintiff, he wondered it was not worse, owing to its own weakness, and said, "My God, my God, how does this house stand?" first saw the chimneys in shop cut away on this day. The Monday before house fell, examined it three times; asked plaintiff again, as he had done ten days previous to fall, to send for his builder to take charge of 82; plaintiff said he wrote for Dunne; pointed out to plaintiff how rere bressumer was resting on flank wall without an upright; told plaintiff he would not guarantee the safety of the house one hour; plaintiff asked defendant to protect it; remained to see rere bressumer shored, as he (defendant) did many civil things for him; never got permission to lay beams or other pieces against plaintiff's wall; never contracted with plaintiff; not aware of a *custom* of shoring adjoining houses; could not shore up without entering, but could brace externally; if a house was shored business should be suspended; hard to tell how 82 could be kept up; shoring a house not an expensive business; if shored thinks it would have stood; took more than ordinary care.

Cross-examined by Dr. Heron.—Did not know were there 50 bricks in the 33 feet depth of 83; could not tell where 50 cracks would be in 33 feet—all cracked; considered front of 82 safer and better without front stays or lateral braces similar to those set to 84, as the front and flank of 82 were not bonded. Employed one foreman at 30s. per week, and two labourers at 10s. per week each, to take down; would not put many men on the work from cautionary motives; had the bricks lifted from wall to hods and carried down, so that no weight might be on floors; contracted with an excavator to clear premises; never took a house down entirely before, nor used lateral braces to fronts or reres; cleared the under part of William's & Gibbon's house, in College-green, and put it on its legs, used no braces. In answer to juror, 83 was 45 feet high, 82, 48 feet, and chimney-stacks 17 feet high, top of roof about 56 feet; not a shade of danger at this time; directed chimneys of 82 to be taken down.

James Toole, foreman, stated there were 7 struts in top range, and vertical pieces 10 to 12 feet long and 9 in. by 3 in.; cross cut all the struts 26 feet long, except 3 or 4. Basement of 82 overhung 1½ inches in 9 feet; did not touch wall at that point; built wall on old foundation; could not discern any failure in plaintiff's story post. Trimmers of stairs of 83, 9 in. by 3 in., were let 4½ inches into flank wall of 82: roof of 83 was supported by a piece 4 in. by 5in., leaning on front, centre, and rere walls, and bearing against flank of 82; gutters, sheeted, leaded, and protected by weather slating nailed against 82 flank. Is sure there was an ancient angle stack in 82; the poles or struts never buckled. Cross-examination—set three struts to rere 5 days before house fell; struts were barely tight enough between walls to bear their own weight; first trial of his skill in works of this nature; struts vibrated by storm and omnibusses passing; might be agitated by those and the coal drays.

Benjamin Norwood, a retired builder—Saw the premises braced, which, in his opinion, was well done, and defendant said so; was not aware of the alleged custom; but, whenever he executed works of this kind, he shored, braced, and strutted without accident.

Samuel Leech, builder, refused to make an alteration in 1854, for O'Reilly, in consequence of the rere of 82 being so bad—being previously employed on the premises in jobbing.

Michael O'Brien, Bacon, Finney, Lalor, Murphy, Doyle, were examined severally as to their departments in connection with the premises, and substantially deposed to the previous evidence of the defendant and his witnesses

Sir Thomas Deane, on direct examination, deposed that at request of defendant he examined the premises after the fall of house No. 82, in company with Mr. Jacob Owen (late architect to the Board of Public Works); found that the foundation of No. 83 was about 7 inches above that of 82; believed that it was marvellous how the fallen fabric stood *at all;* would not sleep a night in the house. Gave it as his opinion that if props were put in front they would have pushed the front wall in; that it was an impossibility for 82 to stand during the taking down of 83, without internal shoring, and even doubtful with that precaution; that it might have kept up the floors, but not the chimney-stacks, whose great weight was the main cause of the fall, owing to their topheaviness, and combined with the storms prevailing in January, 1859, the antiquity of the house, and the ruinous character of the alterations carried on in

---

[*] Omitted from plaintiff's evidence.

1856, by Mr. James Donnelly, under the direction of Mr. Caldbeck, an architect; was not aware of any *custom* in Dublin rendering it incumbent on the contracting builder to prop up adjoining premises on his own responsibility; could not account for the front wall not bonding into divisional wall between 82 and 83; believed the precautions taken by defendant in shoring up were sufficient, and that circular struts were better than squared pieces of timber; knew defendant to be a most competent and respectable man; executed many important works under his (Sir T. Deane's) directions—amongst the rest, the Queen's College, Cork, at a cost of some £30,000 or £40,000; had the highest confidence in his integrity.

The cross-examination by Mr. Armstrong, Q.C., elicited, in addition to various other matters, that if the *style* of the new Kildare-street Club-house could not be pronounced by him, that he should promise it to be *stylish;* that he had *not* read in one of Smollet's works of a man who, to convey an idea of the quality of his house, always carried a brick in his pocket, and, presenting it to enquirers, said, "Judge for yourself;" that as regards the fallen house, and the proprietors of those adjoining, he (Sir T. D.) would say, "A plague on *both* your houses" (laughter); could not say whether the storms in question occurred *before* or *after* the fall of the house; was in Cork at that period, and read of the storms in the newspapers; had never particularly noticed the house 82, though he had passed through the street, thought that if more than ordinary precaution had been taken. the house might not have tumbled so soon.

Mr Jacob Owen, architect—Was for many years architect to the Board of Public Works; was present with Sir. T. Deane at the inspection of the ruinous premises, and corroborated his statement, but admitted that the house 82 could have stood without 83, if effectually shored. braced, strutted, &c.

Mr. George Wilkinson, late architect to the Poor Law Commissioners, in answer to counsel, stated that the house 82 could not stand of itself; poles used were quite sufficient in quality; preferred the circular of the same area to squared pieces of timber; one pole ought to support the house; no necessity for front or lateral bracing. On cross-examination, stated that in sinking foundations parties were bound to protect adjoining premises from injurious consequences; and the same principle applied, he supposed, to the superstructure.

Mr. E. H. Carson, architect—Was experienced in the taking down and rebuilding of houses; believed the bracing and other precautions adopted by defendant were sufficient; knew the premises, 82; noticed them at one time previous to their fall to be in an insecure state, and hurried out of them; examined them after the fall, and found the material of which they were composed to be rubbish; was not aware of any custom involving a builder in responsibility for safety of premises adjoining those he was under contract in rebuilding; believed that it was the duty of the architect to put the proviso in the specification, and whether or not therein, the contractor charged for it in his extras.

The Chief Justice (Monahan), at a late hour, reviewed the evidence on both sides most comprehensively, and at great length, leaving to the jury to weigh the conflicting statements, and the main points, as to whether or not both the negligence or incompetency of the builder and his responsibility by *custom* had been satisfactorily proved,—if so, to what extent damages should be calculated; and if not in their opinion upon the evidence that they should find for defendant.

Sergeant Fitzgibbon, on behalf of defendant, took some exceptions to the learned judge's charge, after which the jury retired for an hour and a half, and returned into court announcing their disagreement, being equally divided—*six* for a verdict, and *six* against. Mr. Alexander Parker, a juror, suggested that the jury might be permitted to resolve themselves into a court of arbitration, with a view to arranging the question; and the judge, in complimentary terms, assented, provided it met the approbation of counsel. Sergeant Fitzgibbon, however, declined, stating he would advise his client to abide the law of the case; and ultimately the jury were discharged without a verdict.

The New Catholic Church of Crossmolina.—This building is stated by the *Tyrawly Herald*, to stand on a beautiful elevated site on the banks of the river Deel, commanding a view of the town and surrounding districts. The church comprises nave, transept, and chancel, with tower and broached spire. Length from east to west, 115 feet; from north to south, 90 feet; tower 18 feet square, with four bell stage windows, to be finished with a handsome broached spire and spire lights—entire height 180 feet. The apex of the roof to be 45 feet high; timbers to be stained and varnished, and prepared for the introduction of tracery at some future period. The windows at each end of the transept and chancel are triple lighted, 10 feet wide and 20 high to apex of centre light. The style of building is the simple or lancet-arch Gothic. The progress of the building is likely to be interrupted for want of funds.

OBITUARY.

THE LATE MR. JOSEPH WELLAND, ARCHITECT.

Within the last four months it became our painful duty to announce the demise of two members of the architectural profession in this city, and now with a sincere regret—in which we feel confident we are unexceptionally joined not only by the class patrons of this periodical with whom by avocation the deceased was identified, but by a very numerous circle of friends, acquired both in an official and private capacity—we have to add a third to our obituary.

Mr. Welland was born on the 8th of May, 1798, at Middleton, Co. Cork, and served his apprenticeship as an architect to the late Mr. Bowden, of Blessington-street, in this city. He enjoyed an extensive share of business, and amongst his numerous works we may name Monaghan Gaol and Court-house. The deceased was one of the architects of the Board of First Fruits for about 7 years, and on the Ecclesiastical Commissioners being constituted in 1833, he was one of the professionals appointed by that body for each of the four provinces. In 1843 the Commissioners determined to centralize the architects' department, and Mr. Welland became sole architect, a post which he maintained with much ability—resulting in a complete reformation as to architectural character of ecclesiastical structures for Established Church purposes throughout the country—and retained till his death, which took place on the 6th ult., in his 61st year. Considerably more than 100 churches have been erected or are now in progress after his designs, besides numerous enlargements, restorations, alterations, &c. Some of the principal are Magherafelt and Ballymena, Co. Derry; Ballymoden, Bandon; and St. Nicholas', Cork; St. John's, Limerick, &c., &c. In judging of the deceased architect's works while acting for the above boards, it must be borne in mind that he, like many others in the profession, had to contend against the difficulty imposed by limited funds at disposal, yet his designs are marked by a truthfulness and suitability of character, an effectiveness of detail and imposing proportions. Mr. Welland was interred in St. George's burial-ground, where also rests Francis Johnston. His successor will be appointed on the 7th instant, and we learn that there are numerous candidates for the office, which is worth about £700 per annum.

We have likewise to announce the demise of Mr. Hugh Carmichael, architect,—pupil of the late Wm. Deane Butler,—a gentleman of high professional attainments, and much respected.

KERFS AND COGITATIONS.

BY A CRAFTSMAN.

TRACING 1.

Trades in general have their historic memoiries and the history of any particular trade is a portion of the history of the civilization of man, prompted by necessity and enlivened by invention. But among the crafts now occupying a prominent position in the van of an all-practicable age, there are few or none which won more laurels or have worn them worthily so long as the kindred crafts of Carpenter and Mason. Though the almost everlasting handiwork of the latter stands intact after the lapse of centuries, still the constructive genius of the other peeps out from the bed of each moulded joint, cylindrical curve, and each winding surface.

Eighteen centuries of Christian civilization and progression have stamped their fiat on their achievements—"the burned *debris* of Herculaneum and Pompeii," and the nondescript remains of Nineveh. From the earliest times, though the nature of those crafts rendered them inseparable, yet jealousy was not unknown—fierce rivalry betimes and for long periods existed. In the early Christian churches of our own and other countries, we have proofs in their stone roofs of the one striving to dispense with the service of the other. Those jealous phases were more or less frequent, till gradually uniting and working in unison they left us some grand specimens of their united handiwork in the groined arch, mighty dome, the old baronial hall and staircase, and in the glorious old open roofs of the cathedrals of the middle ages. The saw cut with unsatiable kerf through the oaks of the primeval forest, and the adze plied, and not in vain, to furnish the necessary scaffolding required in the absence of machinery. Machined planes were requisite, and the application of the "powers," more or less rustic in their adaptation, had to be tried and borne with, and after all, oh ye world of inventive seers! what have *they* not achieved? and by achieving, what need *they* be ashamed of? The temples of their gods are yet standing, though the spirit of their creation be the myth of a mystical age, and which, like the round towers of this green old land of ours, are still pointing their cone-crowned summits towards heaven, defying time and posterity, though they have long forgotten the names of the heroes that built them.

C. C. H——y.

Mr. Foley, R.A., has in hand a statue of one of the Brothers in Comus; this is understood to be intended for his diploma work upon his election as Royal Academician.

ORGAN BUILDING IN DUBLIN.

THIS branch of art manufacture being one of the few remaining in which our countrymen are to any important extent engaged, and maintain a position of excellence at home, the following brief sketch of its history, and the details of manipulatory operations connected with the production of that noble instrument, "the organ," must prove interesting:—

During the latter part of the last, and commencement of the present century, there resided in Dublin a justly-celebrated organ builder and harpsichord maker, named Ferdinand Weber, whose instruments were distinguished for excellence in materials, finish, and tone. The organs in St. Werburgh's and St. Thomas's Churches are the only specimens of his manufacture, as we are informed, now remaining in the city. To him succeeded Woffington (the builder of the organ lately burnt in St. Andrew's Church), Lawless, Hull, Leaman, and others, who, however—it must be admitted with regret—did not follow the laudable example of their predecessor, but permitted the character of Irish organs to become much deteriorated. They have been succeeded by the Telfords of our own time, who by their talents, industry, and integrity have attained, in the manufacture of organs, a position of which they may justly be proud, and to which they have imparted a character for national celebrity. As an evidence of the appreciation in which the productions of these manufacturers—who, it must be conceded, without prejudice to others in their line, take precedence in their art—is held elsewhere, we may name that they have built the organs at the Colleges of St. Peter's, Radley, Oxford; St. Aidan's, Birkenhead; and Turvin Hall, Chester: at the parish churches of Weeton, Yorkshire; Padstow, Cornwall; Shepperd's Burton, Frome, Somerset; Douglas; Penzance, Cornwall; St. Ives, Cornwall: those for the Earl of Harewood, Countess Dowager Dunraven, Clearwell, Gloucestershire; Countess of Mayo, Lord John Thynne, &c.; and for New Zealand Wellington Church, with many others. To enumerate in detail their various works in this country, would be to step beyond the bounds of our province as regards preference to individuals, but in justice we present the information approximately in the following brief summary, viz.:—*Nine* cathedrals, including Limerick, Kildare, Christ Church (which is a magnificent instrument), Dundalk, &c.; *six* collegiate halls or churches, embracing Trinity College, Dublin, Maynooth, All Hallowes, &c.; the Chapel Royal, St. Matthew, and Dublin Castle, the Freemasons', Antient Concerts', and University Choral Halls, and Catholic University, in this city; *twenty-two* monasteries, convents, and asylums; and nearly *one hundred* parish and other churches throughout Ireland. Among those now in progress for our city we may include the instruments intended for St. Catherine's Roman Catholic Church, the Catholic University, the Royal Hibernian Military School, and St. Saviour's Dominican Church. The former we had an opportunity of inspecting on the occasion of a recent visit to the extensive manufactory of the Messrs. Telford, and it will be in two cases, occupying each side of the west window, the performer sitting between, and have three benches of keys, pedals, and pedal pipes. The latter will, we understand, be unequalled in Ireland, and will be a fine pedal instrument of 6 stops, with open diapason of 32 feet. The case will extend 37 feet in height by 26 feet in width (designed in style of Gothic, suited to the surrounding edifice, by the architect, Mr. M'Carthy), the front pipes illuminated, to contain three benches of keys, and the cost about £1,200. Mr. Telford was engaged making the working drawings for this instrument, and we cannot conceive an occupation requiring more universal information and skill than a clever organ builder. He must have practical knowledge as an architect, engineer, carpenter, joiner, worker in metals; be versed in music, acoustics, pneumatics, and mechanics.

We were much gratified with the bustle and business tone pervading the building. On the ground floor some men were engaged casting the metal in sheets to make the metal pipes. This metal is a compound of tin and lead, and is melted in a cauldron holding about a ton and a-half. When properly mixed and ready, it is poured into a box, which is moved along a bench, leaving behind it a sheet of liquid metal, of the requisite thickness, on a lining of ticken. The pipes are cut out of these sheets, turned on mandrils, and soldered up. Others were engaged on a large bellows; some at the case and training; others at the sound-boards and action; every portion of the instrument being made on the premises, with the exception of the keys. Drawings are first made of every portion of the instrument, and then each part is allotted to that particular branch. Numerous hands are busily employed on an organ for His Grace the Duke of Leinster, at Carton, and the greatest care is taken with every particle to produce the most perfect workmanship and finish, and when erected no doubt will contribute an additional specimen of scientific ingenuity and superior workmanship. Messrs. Telford are also engaged on large organs for Shane's Castle, and for St. Mary's Church, Youghal.

It gave us very much pleasure to see so much doing amongst us in this noble art; but if Irishmen would only behave with more patriotism and common sense, there would be *many* such, and *more* extensive manufactories in every branch.

Messrs. Bevington & Sons, of London, have completed the new organ for Carlow Catholic Cathedral, and it is said to be a powerful and handsome instrument. It was much wanting in that fine spacious building, which has been receiving internal decorations. The same firm also erected some years ago the small organ in the private chapel of the College, adjoining the Cathedral.

The organ of the Catholic Church of Newcastle, which was built by Mr. White of Dublin, has been finished.

The Home of the Mechanic.—What a contrast does the home of the sober, industrious mechanic present to that of the idler and the dissolute? In the one there reigns peace, comfort, and independence; in the other, misery, hunger, and dirt. The one is a little palace, in which the contentment king's court holds absolute sway; the other a hovel, where vice breeds and spawns depravity on the highways of life. One glance into the interior of the former dwelling is worth a whole day's inspection of the splendid one of a noble; for the former is associated with the happiness of thousands, the latter with that of a single family. The mansion of the noble may be decorated with the gems of art and genius; it may present a more than Oriental luxury of appearance; but the contrast between it and the cottage of the sober artizan is immeasurably in favour of the latter, as far as those higher estimates of human happiness, which are based on something superior to mere superficial grandeur, may be allowed to sway our judgment. In the one we see rugged labour, the soul and sinew of the nation, reposing like a giant gathering strength for renewed exertion; in the other we perceive effeminacy "lolling on a lewd day'coach," deploring the slowness of that time which silently and slowly brings its votary nearer to that end which, in his old age, he dreads, and endeavours by all manner of shifts and ingenuities to avoid. In the one there is a strait-laced, artificial discipline, which freezes the heart and contracts the mind; in the other an innocent freedom, which tolerates the laugh and the jest on all occasions, and yet allows the graver moments of existence to exert their salutary influence.

MEANS OF PREVENTING THE DECAY OF STONE.

Touching this subject, and the qualities of certain stones used in London for building purposes—amongst others, the Cornwall, Aberdeen, and Peterhead granites, the Craigleath, Dundee, Arbroath, Yorkshire, and Tunbridge Wells, sandstones, the Anston and Bolsover *magnesian*, and the Portland, Purbeck, Caen, Ketton, Barnack, Bath, Ranville, and Aubigny *carbonate* limestones, &c., &c.—an excellent practical paper was read recently by Mr. George Burnell, C.E., before the Society of Arts. The author notices at some length individually the products of France, England, Scotland; but it seems to be a matter of regret that a paper so ably handled did not extend to the review of those yielded by quarries in Ireland, where the prematurely perishable article—whether granite, lime, or sand stones, all of which are found in considerable quantities—though proportionately less than in the countries named, nevertheless to some extent *does* exist, and a notice of which would have rendered his paper more generally instructive to *our* readers. With exception of the Caen, Portland, and Bath, Yorkshire—for flagging purposes—and a couple of instances of Aberdeen (polished), the stones named above are comparatively unknown here; but, as the means of preventing decay applies equally to *all*, we subjoin his remarks on the best to be adopted.

"The problem of protecting the surface of a soft building stone, after every precaution has been taken, be it observed, to prevent the internal absorption of moisture, seems to me to have been the most successfully solved by Ransome's last patent process. In this process, a fine precipitate, clothing the whole of the pores of the surface of the stone, is produced by firstly cleaning the stone carefully from dust, or other extraneous matters; then the stone is made to absorb as large a quantity as possible of the silicate of soda or potassa, and when this solution has dried into the stone, a second wash is applied, consisting of the chloride of calcium or of baryta. In practice, Mr. Ransome uses the most frequently the silicate of soda and the chloride of calcium; and the effect of the respective applications is, that a double decomposition takes place in the washes, giving rise to the precipitation of a finely crystallised silicate of lime or of baryta, in the pores of the stone, and an efflorescence of extremely soluble salts of the chlorides of soda or of potassa. The former remain in the pores, the latter are speedily washed away by rain. As the rate of contraction and expansion of the silicate of lime is, as nearly as may be, the same as that of the stones it is intended to protect, there is no danger of the precipitate being detached by this cause. It may be added, that Kuhlmann's process is only applicable to the preservation of the carbonate of lime, whilst Ransome's process is equally applicable to that class of materials, or to the sandstones, or even to bricks, or plaster, or cement. It was precisely to this process also that I referred when speaking of the use of chalk as a building material, and I am convinced that, by its application, that abundant and economical substance might be very advantageously applied to our daily wants.

"Perhaps it is going a little beyond our immediate subject, but I cannot refrain from saying that the principle of the double decomposition applied by Ransome to stones, might be applied to the precipitation of a soluble glass upon woods or textile substances, and even to the protection of timber from the attacks of the boring worms.

"There are, however, many economical and constructive reasons for resorting occasionally to the use of soft, easily worked, and, as such, almost always perishable stones. In such cases, those stones must be isolated from ground, or other damps, as effectually as possible, and their exposed surfaces covered at once with an efficient protecting coat, before the process of saltpetreing can commence, and I believe that Ransome's process is the best which has been yet presented to the public for this purpose. Whatever process may be adopted for protecting the surfaces of soft stone, it is, moreover, necessary to pay attention to the constructive law of laying them upon their true bed, and also to protect the more exposed portions of the work by covering them with harder, more resisting, and impermeable materials. Even the latter materials themselves are at times exposed to decay between wind and water, and, therefore, every possible precaution should be observed to limit the range of the absorptive powers of the stones—the first and foremost precaution for basement works being to establish an effective drainage all round the building, at such a distance from it as to prevent the capillary action of the stones themselves from obtaining any supply of moisture from the ground, In the upper part of a building it is equally essential to prevent the rain from lodging upon any portions of the stone work, especially when absorptive stones are used above projections likely to arrest falling water."

Professor Ansted, F.R.S., said, as he had taken considerable interest in the subject of building materials, and the decay and preservation of them, he would offer a few remarks. Referring to Ransome's process, he stated that Mr. Ransome had re-invented Kuhlmann's manufacture of soluble glass. Mr. Ransome tried the same experiments and found them fail, and then it suggested itself to him whether, after all, he could not produce an effectual process, which should be independent of the dryness of the atmosphere; and, by combining the first wash of the soluble glass with a subsequent wash of chloride of calcium, he seemed to have succeeded—theoretically he had been, no doubt, successful. The double decomposition took place immediately, and the result would, of course, be the formation of a chloride of sodium and silicate of lime. What was the silicate of lime? They had only to look at the specimens of mortar which they found in old buildings to see the effect of this silicate of lime deposit. The cause of that peculiar power of the mortar to attach different pieces of stone together was, that the grains of sand which were made use of in mortar became coated with a silicate of lime, and the surface also to which the mortar was applied was coated in the same way; and this silicate of lime adhered so strongly to substances foreign to it, which it attached together, that practically the most perfect junction was effected; and when the mortar was very old, the substance of the stones would separate more easily than the mortar. If they could deposit this thin film of silicate of lime, they would do all that was required. In large quantities silicate of lime was not so available as in smaller quantities. There was something in this thin film attaching itself to a foreign body; and it was the particles attaching so strongly to each other which produced the remarkable effect which was found in old mortar. But still no doubt time had something to do with it. The deposit of the thin film of silicate of lime, he imagined, was hardly in a crystallized state, but no doubt this deposit was the whole secret of the success. There could be no doubt but that the silicate of lime was deposited, for all who looked at that part of the Houses of Parliament which had been washed by Ransome's process, after having been exposed for four winters, would see how the case stood. It appeared that there was too much of the silicate put in, which had given an unsightly appearance to the stone. That, however, had been corrected since. The surface there was very distinctly coated with a substance which was so hard that he could not scratch it with a knife; and though there was considerable efflorescence upon the surface acted upon in this way, yet this could be washed off. The efflorescence came off easily from the whole surface; therefore, as far as the test of these four years was concerned, the results must be regarded as satisfactory. The other instances of the application of Ransome's process with which he was acquainted were not so old as that to which he had just alluded, and consequently were not of so much value. But he believed there had been no efflorescence in the case of the chapel at Bloomsbury; and of the other cases he could not say more than that they had the appearance of being in a satisfactory state.

Mr. Robert Hunt, F.R.S., was desirous of correcting what he considered an error, into which the author of the paper, his friend Professor Ansted, and the last speaker had all fallen with respect to the decay of granite. It had been stated, as the opinion of those gentlemen, that the disintegration of the granite was due to the decomposition of felspar. He was prepared to maintain that it was not due to that course. Mr. C. H. Smith had stated that the China clay was produced by the decomposition of the felspar with the granite, and that this was going on at the present time. He (Mr. Hunt) was prepared to prove that such was not the case. He was prepared to prove that the China clay, so far as human observation could go, never was true granite; and also, that atmospheric decomposition acting upon felspar, had never gone to the depth of 300 feet, at which depth they found finer China clay than they did nearer the surface. He could take them over miles of country strewed with felspar. The quartz was gone, but the felspar remained. His attention had been called, during the last two or three years, to Ransome's process. It appeared to him more satisfactory than any other he had met with. There they had a silicate of potash applied to the stone, the surface of which had been rendered as clean as possible. The result was, absorption. They then applied to the surface ordinary muriate of lime, which penetrated within the stone by two different actions, the one being the force of capillary attraction, the other of chemical affinity. Chloride of potassium and silicate of lime were formed; the one being soluble was removed by rain, and the other remained to fill the pores. The great success of this operation, which after all could only be decided after a lapse of years, depended upon the fact that by filling up the pores with this silicate of lime, they prevented the cosmose action going on within the pores of the stone.

Mr. Robert Warrington, F.R.S., said that he had examined specimens of the efflorescent salts upon the surface of the stone in the Houses of Parliament, and, on scraping it with a knife, great quantities of the stone came away in a powdered state. He had also taken the efflorescence from the surface of stones treated by Ransome's process, and he found that where the grain of the stone had become indurated by this means, the efflorescence took place without disintegration of the stone itself. The process seemed to resolve itself into this:—The porous stone absorbed the wash of silicate of potash which was placed upon it. When this was dried upon the stone, the solution of chloride of calcium was applied. Wherever this solution of the silicate of soda had gone, it had coated every exposed particle of the limestone. Directly the chloride of calcium came upon the coated particles it converted the silicate of soda into a silicate of lime. This was at first a thick gelatinous coat, but by drying it became indurated, and the older it was the more perfect must be the induration.

The Chairman said he was sure they would consider that the advantage which Mr. Burnell had conferred upon them by reading his paper had been increased by the excellent discussion it had evoked. Mr. Ransome's process had witnesses in its favour of no common ability and position, and he most sincerely trusted that time would confirm the good opinion which had been expressed of it. He asked them now to give their best thanks to Mr. Burnell for the paper he had read.

The vote of thanks was then passed.

The paper was illustrated by a collection of building stones commercially known in this country.

AN ENGLISH MODEL FARMSTEADING.

The following are a few particulars of a model farmstead, now in progress of erection at Longleat, Wilts, for the Marquis of Bath, and designed by Mr. Wilkinson, who is (as we understand) the brother of a respected member of the profession in Ireland. The design is thus described by the *Illustrated London News*:—

"The Marquis of Bath's buildings comprise a complete building establishment (which every estate of magnitude should possess), in addition to, and in connection with, the farm buildings.

"The timber-yard and workshops are situated on the north side of the barn buildings and cart-sheds, the latter forming a range of buildings standing in a line east and west, and facing south. The workshops or building establishment comprise, on the upper floor, joiners'-shop for ten benches, provided with machinery for sawing, morticing, tenoning, &c.; a shed adjoining the shop for storing sawn timber; and a drying-room for boards and joinery, over the boiler-house, heated by steam. On the ground floor is a carpenters' shop, a blacksmiths' shop, and sawing-shed, fitted with a long rack-bench, for converting round timber; a bench for sawing deals and planks; and one for cutting up the slabs and blocks, which fall as they are cut into a store-room below, ready to be supplied to the boiler fire, the boiler being on the same level and near thereto. The engine and boiler-house adjoins the sawing-shed, and will contain a 16-horse power engine and boiler. There are also a clerk's drawing and pay office, glaziers' and painters' shop, and ironmongory stores, belonging to the building premises, and contained in the long range of buildings running east and west, the other portion of which is appropriated to the farming department, and contains granaries, store-rooms, straw-barns, thrashing-floor, mill-rooms, corn-dressing room, chaff and caving stores, men's mess-room, and cart-sheds. A covered way connects these buildings with those standing in front of them, and which are under five connected roofs running parallel to each other, containing capacious roothouse, stabling for a large number of horses, nags' stable, and stalls for cows and feeding beasts, calves'-pens, spare houses, pigs' boxes, and foodhouse, and two large covered yards. These yards are excavated four feet below the other floors, and arranged to receive by the least possible amount of labour, and without the use of barrows, the whole of the refuse from the several places without loss and without underground drainage. These covered yards are constructed with due regard to ventilation, and form comfortable places for store cattle. The manure is thoroughly mixed, and becomes in an excellent state for removal. By this arrangement the old system of forming the manure into heaps and turning it, thus exposing it to rain and wind, and allowing its fertilising properties to escape, is dispensed with. Hence there is a saving of carting and labour, as well as of the valuable properties of the manure. On the east side of these buildings are some open yards and shedding, fowl-yard, and fowl-houses, slaughter-house, and implement-shed. A residence on the west side is provided for the bailiff. The windows overlook the roadway between the buildings, where a considerable portion of the work is concentrated. A dairy is attached to the house, whence Longleat House will be supplied with cream and milk. The upper dwelling-house is intended for the clerk of works, from which he will command a view of the yards and shops. The water supply is from a natural spring on a hill opposite the site, and is conveyed by pipes to a tank placed over the covered way, and thence carried by pipes to the various yards and buildings.

It has been found that on some lines of railway having frequent sharp curves, the flanges of the leading wheels of ordinary six-wheeled engines required to be turned anew every six weeks.

COMPETITION.

NEW HOUSES OF PARLIAMENT, SYDNEY.

Two premiums are offered—viz., £600 for the *best*, and £800 for the *second best* design. The style discretionary; time limited to 1st January, 1861; and plans to be addressed to the Secretary of Public Works, Sydney, to the care of Messrs. Merry and Co., 86, Cannon-street, London, E.C. Messrs. Hodges and Smith, of Dublin, will supply general conditions and a contour plan to Irish competitors; also a photographic view of the locality—an excellent idea—may be seen at their establishment.

THE REFORMATORY AT UPTON.

The Reformatory for juvenile criminals of the Roman Catholic persuasion, now near completion, is situated on a farm of land lately taken for that purpose, near the Upton Station of the Cork and Bandon Railway. The buildings are within five minutes' walk of the station, from whence they can be seen occupying the brow of a gentle eminence, which commands a good view of the country around, and nearly in the centre of the farm. The buildings at present erected are but a part of a complete plan, intended ultimately to be carried out as the exigencies of the institution demand. The main edifice is two hundred and thirty feet in length, and is two stories in height. It comprises on the ground floor, a cloister the whole length, and nine feet in width; a chapel, intended to be used also as a school-room for the present, sixty feet long and eighteen feet wide; a refectory, forty feet by eighteen; a kitchen, three workshops, store-rooms, porter's-room, visitors' parlour, lavatory, bath-house, scullery; and on the upper floor, a dormitory one hundred and thirty feet long, an infirmary, nurses' room, with bed-rooms for the officers and managers of the establishment. The building is erected in the domestic style of Gothic prevalent in the fifteenth century. The walling is of squared rubble with limestone plinth and quoins, and all the window and door dressings and the chimney shafts are of the Cork Clay Company's brick. The cloisters, workshops, &c., are paved with the black and red tiles of the same company. The building was designed by Mr. Richard R. Brash, of this city, who also superintended the execution of the works. The builder is Mr. Richard Evans, also of this city. The cost when completed will be under £3,000. Great economy must have been observed in the carrying out of so large and substantial a building for so moderate an outlay. It is to be ready for occupation in May, and is to be under the management of the Brotherhood of the Order of Charity.—*Cork Constitution.*

AMERICAN NOTES.

A building for a new Catholic Literary Institution is in progress of erection at the corner of Longworth and Vine streets, adjoining the Mechanics' Institute, Cincinnati.

The new Baptist Church at Northville, Michigan, has been dedicated, as also the new Methodist Church at Newaygo, the new Universalist Church at Dowagiac, and the new Congregational Church at Port Huron. The churches alone of the two Episcopal bodies, the Methodists, North and South, number about 14,000. This aggregate gives an average of more than 150 churches built each year since the erection of the first (Old John-street, N.Y.) in 1768—three each week. During the last two years the increase of churches in the Methodist Episcopal Church (North) alone was 970, giving nine and one-third per week, or more than one and a half for each working day of the two years. During the same period 866 parsonages were built—about one for every two days.

The city authorities of Detroit offer premiums of 500 dollars for the best, 300 for the next, and 200 for the third best set of plans for a building to contain City and County Offices, Council Chamber, and Recorder's and Circuit Court Rooms, to be lodged before the first Monday in April. The building to be three stories above basement, to present four stone-dressed fronts, and to cost 200,000 dollars.

The roof of a large school-house at New York was recently lifted off by storm, while 440 childen were under it, and yet all providentially escaped unhurt. The building cost 30,000 dollars; it will cost 3,000 to repair the damage done.

Seven contractors and their sureties have been summoned by the county surveyor of the South Riding of Tipperary, for the next petty sessions of this town, for neglecting to repair the roads. [We hope the example will have a salutary effect on others nearer home.]

The Building News is presenting its subscribers, in parts, contained in each weekly number, with a handsome work, containing a memoir and portrait of Sir Wm. Chambers, and a treatise on "the elements of beauty in Grecian architecture," by Joseph Gwilt.

The ancient Egyptians employed stone tramways similar to that in the Commercial Road, London.

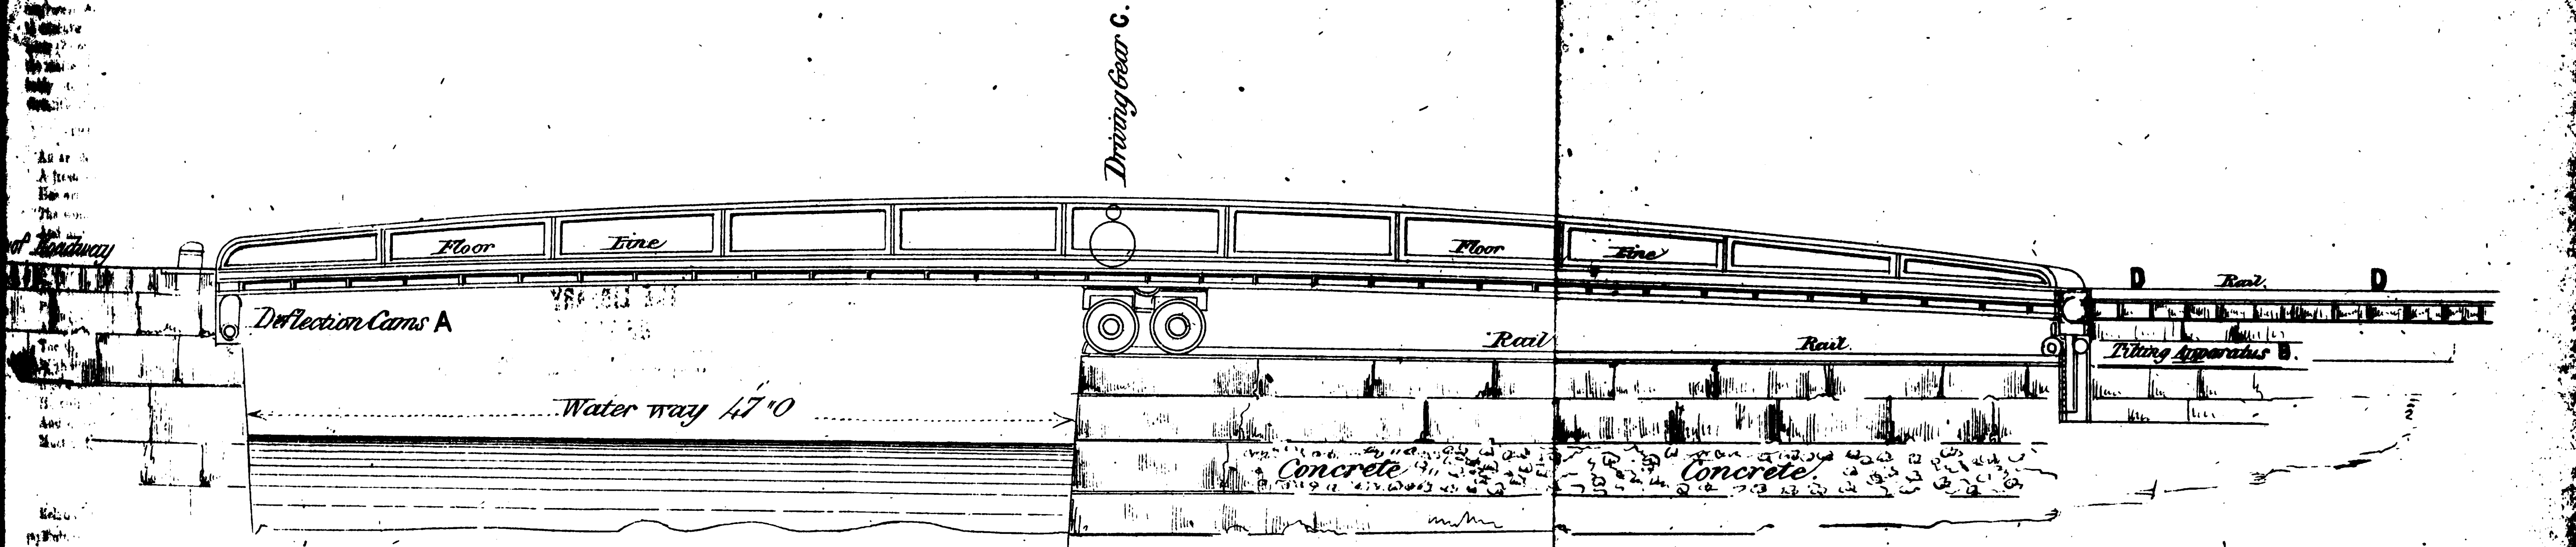
THE DUBLIN BUILDER, APRIL 1860.

NEW BRIDGE ERECTED
GEORGE'S DOCK,
NORTH WALL,
DUBLIN,

G. Christie & Co. Dublin.

KENNEY'S PATENT
NCE ROLLING BRIDGE,
Scale 70 Ft. – one inch.

TURNER & GIBSON,
HAMMERSMITH IRON-WORKS DUBLIN
PROPRIETORS & MANUFACTURERS.



Longitudinal Section

THE FOLLOWING ARE SOME OF THE ADVANTAGES OF THE INVENTION.

Simplicity in its construction & action being longitudinal beams of Iron or Wood, with flooring joists & flooring, balanced & travelling on rollers & raised, opened & shut by suitable Mechanism. Having only one & a continuous motion from the time of starting till either opened or shut.

Having no Back Tray or Shifting Piece as in other Opening Bridges, requiring no intricate or expensive Stone Work, indispensable in Swivel Bridges

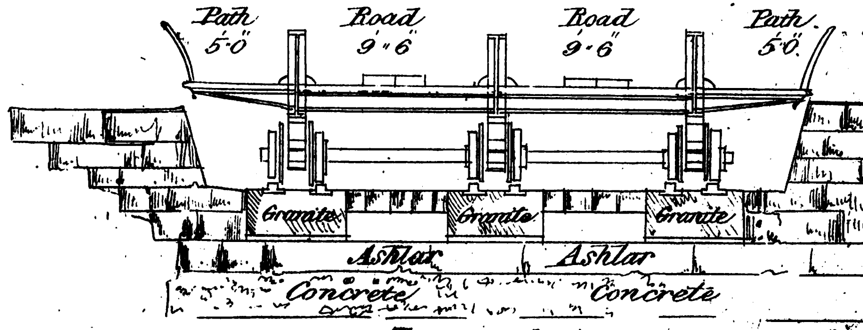
Peculiar applicability for Double Roads & Pathways & for Crossing Shipways into Docks or Canals.

MODE OF OPENING THE BRIDGE.

Deflection Cams at A
by the Apparatus at B
power to driving gear at C

Bridge at B rises becoming
drawn back over ground line D.D.

tion closes & secures the Bridge.



Transverse Section

The floor line of this Bridge can be constructed Level to suit Railways &c.

OF THE
UNIVERSITY OF ILLINOIS

RATHGAR PRESBYTERIAN CHURCH COMPETITION.

Sir,—A little church was recently erected at Sandymount for the Presbyterians, £800 being the originally intended amount of expenditure, and this *heavy* undertaking suggested the idea, that Ireland did not contain an architect sufficiently eminent to engage therein. A worthy gentleman in this town, a member of the British Association for the Advancement of Science, and one of the Caledonian fraternity, was appealed to for advice at this critical juncture. This Mr. D——, being a great importer of seedlings suited to the "Irish soil", remembered that in Stirling a church was built by Mr. Hay, and *hay* was thereon imported,—hence the little *hay*stack at Tritonville. This formed a precedent as regarded the proposed church at Rathgar. *Hay* is now too high for another haystack. So a Mr. Heiton (Hay-ton,—query, a *ton* of *hay*) is the nearest approach, the fancy being still entertained that "no Irish should apply," and no Irish architect is qualified to build a Scotch church in Dublin. Architecture has been called "petrified music," and some of the committee engaged in erecting Rathgar Church keep up the musical idea in trio fashion, playing with *Drum*—, *Fife*, and *Bell*; but no organ will be allowed to speak inside the church, except an *organ of the press* (a Scot also)—but with a *Bell* in the tower, and a *Drum*— and a *Fife* behind the pulpit, no other accompaniment will be necessary. Agreeably with these notions Mr. Heiton, or at least his plan, was brought over and approved of by the *Scot* and his *confreres*, and preparations are now being made to procure a builder to execute the work for the money available. An enthusiastic admirer (?) of the whole arrangement has been trying to commemorate the matter in rhyme, of which the following is a copy (though probably its poetical pretensions under other circumstances would disentitle it to a place in your excellent journal):—

THE CHURCH OF THE DRUM—, FIFE, AND BELL.

An ar-chi-tect from Perth—
A fresh subject for mirth—
Has arrived with his plan,
The wonderful man!!
And in ten weeks or so
He likely will go
And lay the first stone,
And then away *home*.
For he's going to build
A high steeple, and gild
The top of it too,
Without more ado;
And a high niche for *Bell*
He will also make well;
And a bracket for *Scot*
Must not be forgot.
For to *Bell* be the praise,
To the end of his days,
That he did go to Perth,
The place of his birth,
And thence brought the man
With the wonderful plan.
And *Scot* with his pen
Will tell us all when
"He is passing," "and seized
With wonder" "and pleased"
With the bracket so high,
And the niche near the sky,
All worked out "by hand"
By the sons of this land,
For *Scot*, *Fife*, and *Bell*,
Who have earned them well.

Spectator.

Relative to the same matter another correspondent, after various preliminary remarks which we deem unnecessary to publish, asks:—

1st.—Were the committee, or any of them, interested in the adopted plan, and familiar with it before they called a competition?

2nd.—After they first saw it, was it altered and revised to embody peculiar views of their *own*,—and to exist as their own plan, *versus* that of strangers?

3rd.—Did they extend the previously limited time for the purpose of receiving the adopted plan as amended?

4th.—Does their minute book record that they enlarged the amount of money for the *same* plan, giving it an undue advantage, and putting all others to a disadvantage?

5th.—Referring to the terms of the advertisement—that no plan will be paid for unless the one adopted—do they think that the terms of the advertisement are only binding as a whole, or that they can break their part and enforce the remainder?

6th.—And if they will not pay for rejected plans, will they refuse to pay for *wasted* time and *misspent* money?

The plan adopted is, as I am informed, not a new *design*, but a copy of a prior erection in Perth, as Sandymount Scotch Church is of one at Dumblain, "Cold kail hot again," I think, they call it. Mr. Editor, these are strange times we live in—the glory of our city is departing, our sun is set on the ocean wave, and out coat of arms is torn.—Yours, till otherwise advised,

Fitzstephen Blain.

The Cottagers' Society, established by Lord Fitzwilliam, at his seat, Coolattin, county Wicklow, has been very successful; if other proprietors would try this, what a change would come over the face of the country!

It is proposed to erect in the streets of Coventry—the ancient watch-making, ribbon weaving city—a statue of Lady Godiva, of high renown.

CHRISTIAN ART IN IRELAND.

A revival movement in Christian art has of late years been cheeringly and palpably observable in Ireland, and the veil of apathy which for generations had encircled her people has been gradually lifted, and resources developed, which, if matured in the same ratio till the end of the present century, will achieve great things, and mark it as an important era in her architectural advancement. To be sensible of the state of degradation into which ecclesiastical art especially had sunk, needs no penetration into the profundity of historical records, for even the adults of our own day must bear in their mind's eye the ill-proportioned, ill-arranged, rude, blocky, gazebo buildings—happily now few and far between—that studded the country from point to point, where suitably arranged structures have risen in lieu, with tower and spire "whose silent finger points to heaven," and whose *toute ensemble* bespeak their double purpose—of glory to the Creator and honour to the devotion of the creature. To the Mediævalists and Gothicists, before whom the Classicists are and have been paling, are we mainly indebted for this metamorphosis—a remark, we must observe, advanced without prejudice to the disciples of the latter school, under whose directions even now classic churches of chaste design are rising in our metropolis—and in our usual periodical chronicle we are afforded pleasure in adding to the category. Elsewhere in this journal may be found some noted intelligence of new works in this class, and we learn that two metropolitan churches of the old school and "questionable shape" will speedily be mingled with the dust, and noble Gothic structures, with cloud-capped pinnacles and of orthodox proportions, be erected instead.

A VISIT TO THE EXHIBITION OF THE ARCHITECTURAL PHOTOGRAPHIC ASSOCIATION, LONDON, 1860.

Upon a general inspection of this third annual exhibition, recently open, we were certainly pleased with the collection, comprising, as it undoubtedly did, some of the finest works of architectural art, represented in well developed impressions, if we may use that term. It would not be any advantage to our readers to recite the names of all the buildings pourtrayed, as the catalogue is the best exponent; but we will give a general idea,—first of the arrangement, and then of the class of subjects.

The room, about 60 feet by 80 feet, excellently lit from the ceiling, is entered in the centre of one end; all around are hung the photographs, neither too high to be lost, nor too low to be inconvenient for inspection. In the middle are six screens, filled on both sides, and a table covered with portfolios of the display of previous years, from which selections may also be made. Immediately to the left on entering, is placed France not so much out of compliment to our ally, as that in consequence of the large number exhibited—about ninety altogether—and of their great size. The field was open, or rather the walls were clear, for the space they might occupy, and the smaller collections would work into the corners. France, then, takes up half the end and nearly the whole of the left-hand side. Some eight photographs, also on this side, are supposed to represent the Netherlands, Germany, and Switzerland. The further end of the room commences with eleven of Constantinople—but this celebrated city had ample justice done to it on previous occasions; Jerusalem and the neighbourhood are shown in twenty-four. The Roman States, in thirty, commenced the right-hand side; North Italy, including Verona, Venice, Padua, Milan, Murano, and some single photographs to a few cities, take one hundred and ten, the greater part being devoted, of course, to Venice; and Spain, with twenty-six, filled up the other half of the entrance end, and completed the circuit of the room. The screens contained about two hundred and twenty subjects from England and Wales. Extraordinary as it may appear, there is *not one from Scotland or Ireland*. What can be the reason for these two countries having been either neglected by the photographers or disregarded by the Committee of the Association? We believe the former is the truth of the matter. Let our talented native photographers see to it against next year. Our native photographers seem to disregard the advantages offered by their art for architectural purposes, and though our city is plentifully supplied—rather too much so—with photographic portrait artists, we are not aware of *one* who seeks to devote himself to the former pursuits, though to our minds special application thereto would open up a profitable field. Having devoted two good hours to carefully noting the excellencies of these five hundred works of nature, the time came for making a selection. Here we were completely put out—not from the richness of the material, but from the want of really useful subjects for reference and study in every-day art. General views of the Louvre, central porches of the great French cathedrals, west fronts of ditto, doorways filled with figure sculpture, the mosques, views of dilapidated stone walls, or rocky hills at Jerusalem, bridges in ruins, ancient ruins of Rome, Venetian churches and palaces, with the usual selection of views of cathedrals and castles in England and Wales, do not afford a useful fund of matter for improvement, however much they tend to make a good show. The ancient halls were limited to some dozen or so, but amongst them were some charming interiors from Haddon; the entrance to Hengrave Hall we wished to select, but found the impression anything but clear for use. There were no available specimens of English domestic Gothic, and but little more than the well known Palais de Justice at Rouen in foreign Gothic. The purely classic examples of Grecian art were also discarded this year, at which we were surprised; they were so exceedingly admired on the previous occasions, as to have justified their being again exhibited, for of course a subscriber cannot select all he would prefer in one year. Byzantine subjects were also scarce. We would urge the Committee for next year to take steps to secure the representation of some well designed part of a structure, to be accompanied with its details to a larger size. For instance, if Mr. Bedford, who appears to have sent impressions from negatives taken expressly for the Association, had given some of the carved work surrounding the beautiful west entrance of York cathedral, in addition to the general view of it (446), the portions would have been more useful to architects than the north-east view (445), or many others upon which he spent much time—such as the well known subjects at Canterbury, the pretty pictures representing Raglan, Tintern, and elsewhere. Sets, as we have indicated, of such parts would be most valuable to the artist. Except the hospital at Milan (153), and the church at Murano (209), there was little else exhibiting the useful manufacture of terra cotta; whilst for ornamental sculpture, the head of a doorway or two (but which it would not be advisable to reproduce), the bottom of the bronze standard at Venice (257), and a door at Barcelona (267), were truly all the subjects one could find. This species of subject should be, we think, strongly urged upon Mr. Bedford and others by the Committee, or else the Association will merge into a mere show for photographers. We all know the difficulty the present Committee has had to recover lost ground; but something more will be expected from the members of it next year.

Amongst the most noticeable productions are, the (475) monumental brass from Lubeck, dated 1350, one of the largest and finest of its class, taken from a rubbing; the clock at Strasbourg cathedral (65), with a St. George and the dragon, a beautiful picture as regards tone; the almost renaissance sculptured figures in the portal of the cathedral at Berne (71); the side entrance of the west front of Lichfield cathedral, lately restored (305, &c.); with the interior of Haddon Hall (294, 296, 279, 299), before mentioned. The view of St. George's Hall, Liverpool, comprising as it does merely the portico, with the long side in very rapid perspective, is not done justice to, especially as the portico is represented over the boundary wall, the equality of the color causing the wall to appear on the same plane as the steps; thus a very bad and unarchitectural looking arrangement is produced.

It would be useless to describe all these works in detail, especially as the gallery closes before this will appear in type. The above must suffice to afford some idea of the variety of subjects, and we conclude anticipating even a greater architectural treat being provided for the subscribers next year; although in this exhibition the allotted number of fifty for the guinea subscription soon mounts up in the selection, and great is the temptation to exceed that sum.

As all the photographs exhibited belong to the Association, could not the Committee arrange to send the collection, or a *part of it*, to Dublin and other principal towns for exhibition, especially whereever they might be guaranteed against any loss by so doing? The photographers could, no doubt, still supply the works even of past years at the amounts placed upon them. As this might be done during the autumn months, it would not interfere with the spring exhibition in London, and one exhibition in the country in the year would not break in upon the interest felt for the main object. Great benefit might be anticipated from the display to the public of so much good and true art of all styles and countries.

THE AMERICAN INSTITUTE OF ARCHITECTS.

ALLUDING to this Society, established for the *assumed* advancement of the architectural profession throughout the United States of America, the *Architects' and Mechanics' Journal* thus graphically describes its present anomalous position, and one to which for obvious reasons we would direct the *special* attention of professionals here:—

"It was with no little pride that, very recently, we found ourselves permitted the honor of regularly reporting the proceedings of the American Institute of Architects. We gratefully acknowledge the high compliment; but, at the same time, the very pertinent question sometimes occurs to us, *What is there to report?* Except that really fine discussion upon iron between Mr. Van Brunt and Mr. Eidlitz, we have never been able to get anything more than that, at intervals, the same half-dozen members met, said "good evening" to each other, and then adjourned. A might probably tell how that perspective is getting on; B might relate how some shuyster managed to *cheat him out of a job;* while C descants upon the *disgraceful manner* in which his design was thrown aside in some competition. A desultory conversation might then ensue upon the awful state of things in general; upon which D—a jolly good fellow, with an eye-glass—steps in, and *proposes* egg-noggs all round, in true Congressional style. All this may be intensely entertaining, but, for the life of us, we cannot comprehend how it 'has for its object the advancement of architecture in this country.'

"Where are the lectures and discussions upon subjects likely to interest and instruct not only the profession, but the world? Where is the fiery denunciation against the whole race of pettifoggers who have ground, and are still grinding the noble profession into a depth of pollution, from which no Institute will soon be able to redeem it? Where are the rules and regulations—*stamped by the high authority of such names as we see in the Institute*—and given to the public as the code by which the whole profession should be regulated everywhere throughout the United States? Where is the discussion upon competition, not only among architects, but among builders? We are constantly meeting something good and instructive which has been said by somebody or other, either before the Royal Institute of British Architects, or the Architectural Association in London. Why have we not the same to record of *our* Institute? If *nothing* is ever said or done, of what use is the Institute? If *anything* is ever said or done, why has it not been published?

"The very name of the AMERICAN INSTITUTE OF ARCHITECTS invests such a body, in public estimation, with an amount of authority which demands a corresponding amount of action. We write this in good part, deeply interested in the success and progress of the Institute, because deeply interested in the welfare of the architectural profession. All we ask again is, to let us have *something to report.*"

PESTIFEROUS EFFLUVIA FROM THE LIFFEY.

THE indefatigable Mr. Whelan, T.C., suggests for the suppression of this nuisance, a plan comparatively cheap and ready of execution, which is to construct dwarf sluice gates eastward of Carlisle-bridge, and at such a distance therefrom as would not imperil its safety—the safety of the bridge—the dwarf sluice gates to be of timber construction, the piers to be coffer form, 15 feet by 7 ft. 6 in., on a base composed of whole baulk piles, tongued and grooved, and driven into the bed of the river the required depth, to be secured by transverse bolts of one and a half inch square iron, passing through the horizontal braces, the water cuts to be trussed from the bed of the river; those coffers to be filled with bricks laid in regular courses, bedded in fresh dry cement and clean sand; the sills to be the figure of an obtuse angle opposed to the current of the stream, and also formed of whole baulk piles in like manner as the coffer piles, but only to project three feet six inches above the bed of the river for the gates to shut against. This project would cost £2,000, and might be executed in two months. This temporary expedient should be removed when the great tidal gates were completed. The sluice gate might be left open whenever there was a freshet in the river, which always gives from six to eight hours' notice. This expenditure would not be required but in consequence of the whole strength of the Liffey, with all its tributaries, converging at King's-bridge, not being sufficient to cover the bed of the river in its passage through the city in the summer season, even within the narrow limits of the quay walls. Therefore they should for the present purpose avail themselves of the influx of the tide, which gives fresh deposits of tidal water twice in 24 hours, and to retain so much water as will not impede the drainage from the sewers, which would give a depth of 4½ feet on the side walls and 7½ feet and upwards in the centre of the river.

Correspondence.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR,—The suggestion made by "C.E.," in the last number, as to the mode of obtaining architectural works is certainly feasible, but it would be more complex in carrying out than appears at first sight. I believe there is a small private society established in London for a similar purpose. The members meet at each other's houses once a fortnight for selection of works and general conversation; a small annual subscription enables a first purchase to be made, and the books are sent round to each member for perusal; after that duty is performed, it is put up to the highest bidder, or the member who proposed the work for purchase, is allowed to buy it at a certain deduction from cost price. Thus, all the members have had the work in their library sufficiently long to test its merits, which is always desirable to do before buying expensive publications. Dublin might support one; perhaps Cork another; Belfast another. Of course carriage of parcels to adjacent towns would add greatly to the expenditure.—Yours, F. H.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR—A controversy having appeared some weeks since in your columns on the propriety of vending woods by Queen's calliper measure, I send you a circular, under date 24th instant, to show that by *calliper*, instead of *string*, a buyer is brought to pay 22½ per cent. beyond what he receives of the cargo of Greenheart, the actual deficiency varying from 6 to 44½ per cent., through want of squaring, saw-butting, and properly inspecting at the port of shipment.

During the past week, in Liverpool, seven cargoes of wood, shipped from the *like region* with the Greenheart in question, saw-butted and more or less properly surveyed, were sold to 140 customers, whereon a *tare* to each was yielded by the respective importers of one foot for every three feet,—that is to say, the measurement (being that customary in this port) by which these cargoes were sold was 33 per cent. lesss than Queen's calliper.

The above facts show that in one instance the buyer pays for 22½ per cent. *beyond* what he obtains, and the seven cargoes yield a *tare* in favour of the buyer of 33 per cent., respectively reckoned by the Queen's calliper measure.

EDWARD CHALONER.

Liverpool, 28th March, 1860.

Extract from enclosed circular of 24th March inst.:—

"Of Greenheart: it will be remembered that the consumers of this article in this port, in a declaration under date of 26th January last, asserted the integrity of the customary quay measure of the port—and very wisely and properly so—because they who pay long enough for what they do not obtain are very likely in the long run to cease paying for that which they do obtain. These remarks are forced on the writer, the senior measurer of the port, through the fact of the last sale which has transpired, being in respect of a cargo of Greenheart, so badly prepared that the loss of string on Queen's calliper measure ranged from 6 to 41½, averaging 22½ per cent. This information is due to those practical men who made the declaration referred to. When Her Majesty's government buy wood they demand allowances for defects, and very justly so."

Notes of New Works.

The Ballast Corporation are about erecting beacons on the Alderman Rocks, Crookhaven, Co. Cork, and on Wheaten Rock, Sligo Bay—the former to be composed of a *cast*-iron casing, filled with masonry; the latter to be a *wrought*-iron pillar.

Alterations are being made on the premises of Messrs. Lovely, after plans by Mr. Sloane; Mr. Daniel Lawton, contractor.

The Dublin Protestant Reformatory School Committee are about enlarging the house, No. 3, Rehoboth-place, under the direction of Mr. Joseph Maguire, architect.

The Board of Governors of the Masonic Female Orphan School offered a premium of £5 for the best plan for enlarging their present buildings, and to be sent in against 17th ult.

The county court-house at Longford has for some months past been undergoing repairs and alterations.

A new National Bank and offices is to be built at Lismore, Co. Waterford. Tenders are being received according to plans by Mr. Caldbeck, architect.

A house is in progress in Victoria-avenue, Sandymount, for Francis Salmon, Esq.; J. S. Sloane, C.E., architect; Mr. Joseph Pennefather, contractor.

The plaintiff in a memorable action against a respected member of the profession in Dublin is again embarking on "*the troubled sea*" of building operations, in the erection of five houses at Belgrave-sq.

A villa is to be erected at Harristown, near Castlerea, for Mr. James Young, J.P.; Mr. Caldbeck is the architect.

The large farm-offices and hydraulic works at Friarstown are in progress, under Mr. Sloane's directions; Mr. Pennefather, contractor.

In the town of Dalkey many building improvements are being affected, amongst the rest a terrace opposite the railway station, together with a handsome dwelling-house and shop adjacent thereto; Messrs. Barker, builders.

The foundation stone of the Cork Protestant Hall has been laid by the Earl of Bandon; Mr. R. R. Brash, architect.

Tenders are required by the War Department for altering the redoubts on Carrig and Scattery Islands, in the Limerick district; time limited to the 5th instant.

Tenders are required for a new dwelling-house at Fohena, Ahascragh, according to plans by Mr. William Maxwell, agricultural engineer, Ballinasloe.

Mr. A. Egan, builder, of Tuam, has been declared contractor for the roofing and completing of Ballinasloe new church.

Messrs. Crowe, Brothers, have obtained the contract for the erection of new works at the Midland Great Western Railway terminus, Broadstone, comprising the demolition of the present offices, and the construction of new at the opposite side, where the departure carriage-drive or piazza exists, it being found more suitable to reverse the arrangements of arrival and departure; Mr. George Wilkinson, architect.

The monumental oratory, for some months in course of erection at Glasnevin Cemetery, is now complete, and presents—by its rotund form and stone domical roof, terminated by a beautiful glass cross, with polished metal bar therein, and rising from a flush dome light of same material—a feature of considerable novelty. This is the first application—that we are aware of—of glass for such a purpose. The structure is of granite, chiselled and rusticated; designed by Mr. J. J. Lyons, architect; Mr. William Crowe, contractor. Mr. William Turner supplied the handsome metal doors and other iron work; Messrs. Sibthorp and Son, the glass dome and cross, which were specially manufactured in England. A quantity of Rogers's peat charcoal has been introduced into the vault beneath, and ventilating tubes pass through the arch into the oratory wall, and thence to circular apertures in the external frieze, preserving the atmosphere of the vault perfectly free from gaseous exhalations. Total, £150.

ECCLESIASTICAL WORKS—ROMAN CATHOLIC.

THE internal decorations and furnishing of St. Saviour's new Church in Dominick-street are being proceeded with,—the former comprising the colouring, gilding, &c., of the ceiling, the carvings of the nave, aisles, and apse, and the stained glass windows of apse; the latter including the high and side altars, reredos, screens, benches, gas standards, internal porches, organ gallery, and organ itself. The carvings of the nave and apse are quite finished—those of the aisles are in progress—and consist of two series of figures forming corbels—and representing the chief saints of the order of St. Dominick—with foliage capitals of the shafts supporting principals of roof, and foliage string courses between. The high altar will be composed of various marbles, alabaster, and Caen stone, and have an arcaded frontal, with seven figures of angels bearing scrolls. The reredos consist of six groups of subjects symbolical of the Blessed Sacrament and the holy Sacrifice, taken from St. Thomas Aquinas' hymn, the "Lauda Sion," and are surrounded by marble shafts, sculptured and lofty canopies, terminating in figures of adoring angels. The tabernacle is also surrounded by groups of angels, the canopy being of very open work, and the total height 35 feet. The screens separating the chancel from the side chapels are composed of polished marble shafts and elaborate tracery of Caen stone. The floors of the chancel and side chapels will be of encaustic tiles, and the floors of the nave and aisles of black and red tiles, from Minton's manufactory, the spaces under the benches being boarded. The organ gallery, at west end of nave, will be supported on shafts of Irish marbles, with carved foliage capitals and moulded bases. The front of the gallery will be arcaded with alabaster shafts, foliage capitals, and carved string courses and cornices. The stained glass windows in the apse will contain (in the centre) the Transfiguration of our Lord, the Presentation in the Temple, and the Coronation in Heaven of the Blessed Virgin, with other subjects. The last work of the illustrious Hogan, the gift of a generous benefactor, is to be reverentially preserved in St. Saviour's. At one time there was a project of making it part of the high altar; but, after mature consideration, it was resolved that the subject (the *Pieta*, or Dead Christ), and the artistic merits of the work, as well as the memory of the great artist who has been taken from us, deserved a distinct chapel. The *Pieta* will form the principal feature in the altar of the Chapel of the Passion of our Lord; and it is hoped that for ages to come many a devout worshipper will remember both the artist and his generous and unassuming benefactor. Would to heaven that poor Hogan had found many such! The carving is all by Mr. Henry Lane; the painted decorations by Mr. Thomas Earley; the stained-glass by Messrs. O'Connor & Son; the metal works by Messrs. Hardman & Co. The organ is the manufacture of Messrs. Telford, and will be a powerful and beautiful instrument.[*] The contractor for the floor, benches, organ, gallery, and internal porches is Mr. Richard Pierce. The architect is Mr. M'Carthy, R.H.A.

A new church, 120 feet in length, by 55 feet in width, is to be built at Clonea, Co. Waterford, after Mr. M'Carthy's designs. Style, decorated.

A convent is to be built at Kilrush, on a site extending two acres, and presented gratuitously by Colonel Vandeleur; same architect.

---

[*] See page 233.

The new Church of St. Mary, Granard, is about being commenced, the site is on the Moat of Granard. Style, transitional between early pointed and decorated; plan cruciform, with nave and aisles, transepts, chancel, side chapels, sacristy, porch, baptistery, and tower, surmounted by a broached spire—with twelve spire lights—170 feet to top of cross. The length of the building will be 120 feet, 86 feet across transepts, and 54 feet across nave and aisles. Mr. John Bourke is the architect.

The exterior of the Church of St. Mary, Athlone, has been completed. The spire is 190 feet to top of cross. Same architect.

A large convent, schools, laundry, &c., is about being built for the Sisters of Mercy, Newry, also after designs by Mr. Bourke.

The interior of St. Mel's Cathedral, Longford, has been for some time completed. The roof, floor, and ceiling, &c., have cost £8,000. The great portico and campanile are about being commenced. The portico will be Ionic, hexasytle, 90 feet in length, the columns 4 feet in diameter; a campanile will also be added. Mr. Bourke is the architect.

A small church, 80 feet by 22, is about being built at Lenamore, and will have chancel, nave, Virgin chapel, sacristy, porch, and belfry. Style, early pointed; estimated cost of exterior, £650. There are other buildings in contemplation. Mr. Bourke, architect.

Very large additions have been built to the Dominican Convents at Cabra and Kingstown, particulars of which shall appear.

The House of the Immaculate Conception at Inchicore will soon be ready for roofing; it is a portion of the contemplated quadrangle, to be built from designs by Mr. Bourke.

CULTIVATION OF MEDIÆVAL ART.

THE progressive improvement of "our time" and "our country" is daily developing itself in the many new and important undertakings which it becomes simultaneously our pleasure and our duty to chronicle in course; and in no branch is it more apparent than in "mediæval" art, whose adaptation to ecclesiastical edifices imparts thereto a surpassing beauty, delicacy, and richness. An additional gratifying proof is afforded in the fact that some of the most eminent art manufacturers in the sister country have extended their sphere to this metropolis, doubtless descrying with characteristic acumen a favourable position for operations in the centre of a widening circle. Many of our patrons may not be aware that there is in a certain branch establishment of a Birmingham house in this city a staff of artists constantly employed on matters of mediæval art, and who for many years worked under that great master, the late Welby Pugin; also that the same eminent firm have in training, specially for Christian art, a number of "Irish boys," presided over by an "Irishman," and with the best models to work from. On a recent visit to the stone and wood carving works department of Messrs. Hardman and Co. (48, Grafton-street) at 1, Upper Camden-street, we became acquainted with these facts, and as the produce of these artists' hands we were pleased in noticing two very beautiful altars, one in Caen stone, for Ennis Parish Church, exquisitely designed and finished, and the other in wood, for Lisdowney Church, equally creditable though less elaborate and expensive. Such of our readers as desire to view these will doubtless meet a courteous reception from the manager, Mr. Thomas Earley.

USEFUL HINTS FOR HOUSE AND LAND PROPRIETORS.

PARTY WALLS.—The property of the party wall, built at joint expense, vests in the property of the land upon which it stands. A party wall built at the joint expense of two persons, one half of the thickness of which stands on the land of each of the owners, they are not considered as tenants in common of the wall, or land on which it stands. Under the statute the owner of an improved rent is liable to pay the expenses of a party wall, and not the owners of the ground rent. Unless there be an express stipulation to the contrary in the lease, a lessee is bound to do the repairs of party walls. When a lessee for 21 years covenanted "to repair and pay all taxes and impositions," and assigned his term for a small consideration, it was adjudged that he was *not* liable to pay the expense of a party wall, either by his covenant or by virtue of the 14 Geo. II., c. 48, but that it must be borne by the original landlord.

REPAIRS.—In the absence of an agreement, there is no law to enforce a landlord to repair. A tenant is not liable for dilapidations arising by his reasonable and customary use of the premises, and by the efflux of time. A lessee covenanting to leave the premises in tenantable repair, cannot in bar thereof plead that the premises were not in such a state of tenantable repair when his tenancy commenced, hence the necessity of a previous survey. Where the lessor covenants to repair, and does not, the lessee may do it to a reasonable extent, and reimburse himself out of the rent. The covenant to repair and deliver up demised premises at the end of a term extends to erections subsequent to the execution of the lease. Where a house is blown down by tempest, the law excuses the lessee unless there is a covenant in the lease to repair and uphold. A lessee's agreement should be qualified with the words "accident by fire, tempest, or the Queen's enemies only excepted." Repairs, alterations, &c., made by tenant become part of the freehold, and cannot be disturbed.

FIXTURES.—The movables are, steam or fire engines, barrels, vats, coppers, salt pans, pipes, limekilns, baker's ovens, trees and shrubs planted (for a *sale* by a nurseryman), but by a gentleman tenant are *not*, without special permission; a pump set up by tenant, fixtures temporarily attached to the freehold by screws, and which may be removed without injury to the freehold—for example, counters, desks, partitions, gas pipes, grates, ranges, stoves, and the like.

The *non-removables* are, stills, greenhouses, forcing pits, windows (? sashes), doors; solidly fixed to the building, arbours, summer houses, verandahs with supports in the soil. The act of 14 and 15 Vict., c. 25, s. 3, protects the tenant and provides for the removal of farm building, engines, machinery, &c., &c., erected by him, so as the removal do not injure the landlord's ground or buildings.

Monthly Railway Memoranda.

Omagh, Portadown, and Dungannon Line.—By this bill it was sought to make a line from the former to the latter place, with leasing powers over the Derry and Enniskillen. Several witnesses were examined for the promoters, including Messrs. Broughden, Charley, Allen, and G. W. Hemans, C.E.; and amongst those for the opponents were Sir H. Bruce, M.P., Mr. Minnet, Hon. Colonel Cole, M.P.; Hon. Augustus Jocelyn, M. Murland, the Earl of Erne, and Mr. Hawkshaw, C.E., who deposed "that he was building the bridge across the Foyle for the Londonderry Commissioners; it was at present a very good expansion, and would ultimately be a very commodious one; it was intended to form a communication between the two lines of railway; its cost would about be £60,000, and with the approaches £70,000. The bridge was so designed that hereafter the railways at either side could run their railways on to it. The proposed line from Omagh to Londonderry would certainly affect the interests of the bridge injuriously; a T line in general was an expensive and inconvenient one to work." The preamble was declared to be proved.

The House of Lords have granted to the Dublin and Drogheda Company, a line from Kells to Oldcastle, without allowing the Dublin and Meath Company the running powers which were sought by that Company, who are promoting a line direct to Dublin.

A contract has been entered into for the construction of a line of rail from Newtonards to Donaghadee, against January, 1861.

The House of Lords have thrown out the bill for authorising the sale of the Waterford and Kilkenny line to Messrs. Nixon and Co., which was promoted by the English portion of the board of directors, and opposed by the Waterford and Limerick Company.

Reviews.

Memorials of Workers. By George Godwin, F.R.S. London: Robert Hardwicke, 192, Piccadilly.

WITHIN a limited compass the author of this work (the substance of a lecture delivered recently at the Architectural Museum, London) has presented numerous cheering incentives to perseverance by those who daily toil with heavy heart and under a cloudy sky, little apparent prospect of brightness "looming in the distance." He cites as examples of what "perseverance under the most adverse circumstances *may* accomplish"—Bernard Pallissy, the potter, who burned the trellis-work of his garden, and the tables and boards of his house, to melt the composition, in endeavouring to produce enamels, yet, after 15 years, achieved his purpose, which brought him fame and fortune; Quintin Matsys, the locksmith, who wrought the beautiful iron work over the wall near Antwerp Cathedral, also painted the celebrated "Two Misers" at Windsor Castle; Sir Richard Arkwright, "the subterranean barber," the inventor of the cotton machine; Sam Crompton, who played the violin at Bolton theatre for 1s. 6d. per night, to enable him to procure tools to make his spinning-mule, and to whom government subsequently assigned £5,000 as a national reward; Jacquard (the loom inventor); the brothers Gobelins (tapestry of universal fame); Brindley; James Watt; George Stephenson—with whose history the world is familiar; James Tassie, the Glasgow modeller and medallist; Josiah Wedgworth, the potter; Flaxman, the greatest English sculptor; Hogarth; Clint and Turner, artists; Sir John Soane, architect—Dance's errand boy—who rose to fame, left a large fortune and a remarkable collection of books, prints, pictures and antiquities for the benefit of the public; John Britton, Architect, author of the "Cathedral" and "Architectural Antiquities", who as a lad bottled wine eleven hours a day for six years in a dark, cobwebby cellar in London, and then, stealing out at night to visit the book stalls, read a bit on the sly; the late Thomas Cubitt, in 1808 a carpenter without 6d., in 1855 died, leaving some *two millions* of money behind him; George Mickle Kemp, the working mason, the designer of the Scott monument at Edinburgh; Chantrey, the great portrait sculptor, who carried out milk in Sheffield; Mr. John Thomas, Sir Joseph Paxton, M.P.; and a dozen other men, who have taken their place in society and are worthily aiding its progress. The working classes and the public generally owe much to Mr. Godwin for this instructive little work.

An Essay on the Oriental Bath. By Edward Haughton, M.D. Dublin: William M'Gee.

This pamphlet, from the pen of a gentleman whose name is already known to our readers as the contributor of valuable papers on kinkred subjects, details the *modus operandi* in vogue in Oriental countries, and the sanitary effects of the bath on the human frame. The author does not like others advance opinions hap hazard, but speaks from experience founded on personal observation in "the City of the Sultan" and elsewhere. Though the magnificent establishments at Lincoln-place and Bray may by their architectural show surprise the optical faculty of the "Western" and by the completeness of their appointments minister more perfectly to the luxury of the baths; yet in principle they are identical with the old Irish sweating houses, and present nothing of novelty whatever. Their re-introduction, however, has been followed by an enthusiasm almost amounting to a *furore*. We quote the following from the pamphlet:—

> "In the bath we have a pleasure which is not a vice,—a luxury which does not tend to shorten life; which may become universally obtainable; and which, as soon as there is sufficient demand for the article, to give encouragement to capital, must inevitably become cheap. It is the best purifyer of the blood; for even poisons can be thus eliminated in large quanties. . . . It is the best of all cosmetics, for the Mussulman scarcely knows of the existence of these loathsome skin diseases which never reaches the chronic incurable stage which it does with us; and gout itself is known only as a disease of the Franks."

Miscellaneous.

Opening of New Buildings.—The extensive block, some two years in course of erection, adjoining the Four Courts, and intended, as previously noticed, for the Landed Estates Court purposes, has been completed, and will be opened for the transaction of business on the 12th instant. Externally they present little interest architecturally, but bear a suitable and substantial aspect, and harmonize well with the other portions of the quadrangle. Internally the arrangements of the courts and offices, halls, corridors, &c., are suitable and commodious, and the whole erected on a fire-proof principle, and with due regard to ventilation and heating, about which the judges of the courts have recently given officials so many rubs. A consummation devoutly to be wished for has been effected by these structures in the consequent removal of the "nodding" piles about Pill-lane, and which now have been auctioned off as old materials. The plans were furnished by and the buildings erected under the superintendence of the Board of Public Works' architect and clerks; Mr. Meade, builder. The new commercial mart (also already described in the Dublin Builder) is completed, and, though its exterior is perhaps less pretentious than others in the city, it is bold, effective, and suitable to its purpose; the internal arrangements are likewise good, and we congratulate the architect, Mr. Rawson Carroll, on the successful realization of his design, the first of any importance as yet erected by him in the city. Mr. Meade was the builder of this likewise, and, as usual, executed his contract creditably.

Portpatrick Harbour.—Mr. Abernethy, C.E., states that the works proposed for the rendering of this harbour suitable for improved transmission to Scotland, *via.*, Dumfries, can be completed in a period of twelve months after commencement, any excess on the total cost of £20,000. It is proposed that Mr. Abernethy should be engineer in chief at £600 per annuam.

Dangerous Edifice.—The Lord Mayor received a letter from Messrs. Cane and Sons, calling attention to the dangerous state of the house No. 66 Dawson-street. He sent the letter to the engineer, who looked into the matter; and he has since received another letter from Messrs. Cane, to the effect that the house was in a most dangerous position. The house is to be taken down, and there are many others that demand a similar course to be adopted, out of regard for individual and public safety.

Dwellings for Labouring Classes.—Sir William Somerville has introduced a bill to extend the act to facilitate the improvement of landed property in Ireland, and the acts amending the same, to the erection of dwellings for the labouring classes in Ireland.

Machinery.—We are requested to mention that the shafting and *first* motion wheels of the engine at Messrs. Martin & Son's Saw Mills were—as well as the engine noticed in our February number—constructed by Mr. Victor Coates, of Lagan Foundry, Belfast. Two steam-engines of 50 and 25 horse power respectively, besides boilers, &c., have been erected lately by the same manufacturer at the Greenmount Spinning Company.

The Leeds Town Hall.—Recently the scaffolding has been entirely removed from the completed tower of the Leeds Town Hall, and that edifice now presents itself to the eye in all its noble proportions and exquisite details. The hall itself forms a very elegant parallelogram, with a noble vestibule of Corinthian columns, and a correspondingly rich colonnade on the eastern side, which is generally seen together with the front. This construction of the hall was necessary to the perfect arrangement of the interior. The columned tower is original in its design; its height is 225 feet, and it soars above all the other towers and spires in the town, so as to be visible in almost every part of our large borough (which extends 7 miles by 5, with much of hill and valley), and to catch the eye of the traveller approaching Leeds, as the one great feature of the town. If the exterior of the Town Hall deserves so much praise, the interior (that is, the Victoria Hall) is equally elegant, rich, and noble. We are not aware that there is anywhere a hall of finer proportions, or more tastefully and richly adorned. Altogether this is certainly the queen of town halls, and it deserved the historical honour of being inaugurated by the Queen of England.—*Leeds Mercury.*

Progress of St. Louis.—The statistics of buildings erected in St. Louis, for ten months previous to November 1, show an aggregate expenditure of 7,173,000 dols. This amount does not include the appropriation for the Court-house, of 125,000 dols., nor the amount expended this year on the Lindell House, of 150,000 dols. The number of buildings erected is 2,450, of which 2,346 cost less than 20,000 dols. each; twenty-nine cost 30,000 dols.; five 40,000 dols.; five 50,000 dols.; three 60,000 dols.; one, 90,000 dols.; and one 100,000 dols. The assessed value of real estate is over 10,000,000 dols. higher than last year. There have been built this year 24 miles of street railroad, at an estimated cost of 192,000 dols. They employ 95 cars, 300 men, and 784 horses.

New Theatre at Milwaukee.—The new theatre in Young's Building, will be done in about two weeks. It is a gem of a place, will seat comfortably 800 or 900 persons, and will compare favorably with any theatre in the West, for convenience or beauty.

TENDERS

For building Male and Female Schools in connection with Ballymacarrett Presbyterian Church, Belfast, W. T. Matier, C.E., Architect, quantities not given:—

Thos. Magee	£568	0	0	
Samuel Crawford	485	0	0	
John M'Creery	441	0	0	
James M'Cracken	440	0	0	Accepted.
Joseph Croft	435	0	0	
Samuel M'Morran	345	0	0	

H. J., Newry (A greater depth *would* be desirable, to guard against a possible contingency; but we do not anticipate fracture if executed as provided. In *any* case a relieving arch would be very desirable.)

GEORGE SPILL, OIL AND COLOR MERCHANT,

65, 66, & 67, ST. GEORGE'S STREET, LONDON DOCKS.

BUILDING SITES FOR DETACHED HOUSES—BRAY RAILWAY.

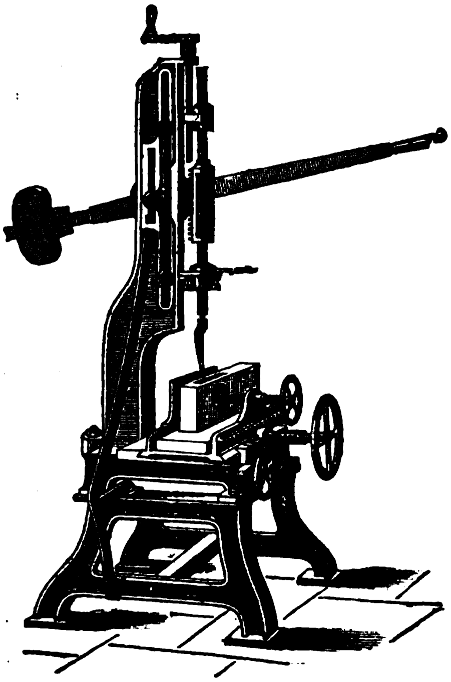
THE Lands of GALLOPING GREEN, FOXROCK, and KERRYMOUNT, are being laid out for Detached Houses, and will be Let in Lots, from One Acre to Ten Acres each, on moderate terms. They are very elevated, and command magnificent sea and mountain scenery; are within Two Miles of Kingstown, and within Three Minutes' walk of the Stillorgan Station at one end, and of Carrickmines at the other, besides which, in order fully to develop these beautiful sites, the Railway Company have arranged to establish a Station on their Line at the centre of Foxrock, from the 1st of September next. Omnibusses will ply between same and Kingstown, for bathing, shopping, &c., as soon as the first 12 houses shall be fit for occupation.

Several Lots are already Let, and some of the Houses nearly finished. Lease 900 years.

N.B.—Superior Bricks, Stone, Sand, and Lime on the Lands, and will be given to the Tenants on very moderate terms.

Lithographed Maps, showing the New Roads, &c., and all further information, may be had from the Steward, at Foxrock; Mr. W. W. Bentley, Foxrock Lodge; or at Messrs. Bentley's Offices,

110, GRAFTON-STREET, DUBLIN.



JOHN CLARK'S
MORTISING MACHINE
(GREEN AND JACKSON'S PATENT).

MAY be seen at work with Messrs. Cockburn, Crowe, Meade, Moyers, Kelly, Geraty, Kennedy, T. H. Carroll, J. H. Carroll, Roberts, Bolton, G. Farrell, R. Farrell, Douglas, Hughes, Alford, Rooney, M. Lynch and John Hogan, Builders, DUBLIN; Messrs. Rogerson, Dawson, and Russell, Railway Carriage Manufactory, Atlas Works, Dublin; Great Southern and Western Railway Co.'s Works, Inchicore; at BELFAST, with Messrs. Fulton, Carlisle, Lowry, M'Creary, Kent, M'Cracken, the Belfast Ship Building Co., and John Ross; at CORK, with Messrs. Hill, Evans, Joyce; at LONDONDERRY, with Messrs. Boyd, Brothers. Testimonials from all parts of the United Kingdom.

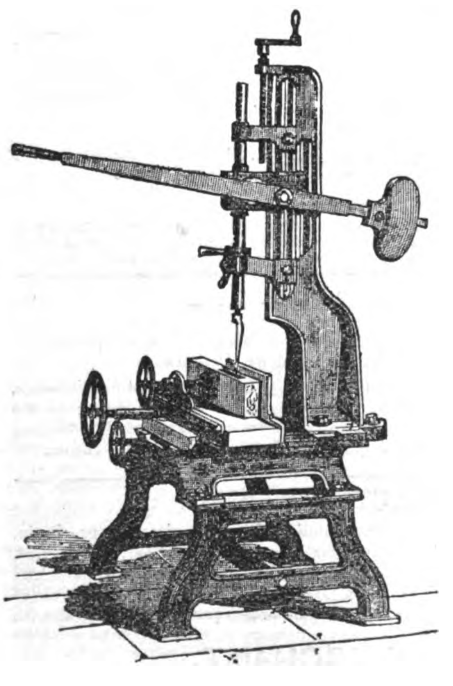
JOHN CLARK, JUN., Manufacturer of Self-acting Circular and Upright Saw Benches, for

SAWING, TENONING, GROOVING,
RABETTING, BORING WOOD,

And Machines for Punching, Drilling, and Countersinking Slates.

OFFICE, No. 12, CALL-LANE,
LEEDS.

GALLON AND BEAN, LEEDS,
Cut & Wrought Nail Manufacturers, & Hardware Merchants,



RESPECTFULLY request all BUILDERS, CONTRACTORS, CARPENTERS, &c., requiring Mortising Machines, previous to purchasing, to examine and test *their patent combined Crank and Lever Machine*, which will Mortise (Tenon and Bore, if required) both Hard and Soft Wood, and is also adapted for Drilling and Punching Iron.

The superiority of this Machine over *all* others consists *in the substitution of a solid wrought-iron plate Crank or Eccentric, by which greater power is obtained, in place of cast-metal Rack and Pinion Wheel, the Teeth or Cogs in which are so liable to strip or break out*—in the direct and perpendicular action of the Lever and Crank on the Cutting Tool, and consequent diminution of friction—in being *stronger* and *less complicated* in its construction, and more *powerful* in its motion—in the *facility* of its *adaptation* to the various depths of material—and in its *non-liability to break* or get out of working order.

This Machine has now been adopted in preference to *all others* by some of the principal Builders in London, Glasgow, Edinburgh, Dublin, and Belfast, who will bear testimony to its being the most powerful and efficient yet made

For further particulars apply to the Patentees and Makers, GALLON, BEAN, and LUMB, LEEDS.

Extract from the Report of the Royal Dublin Society's Spring Show, 1859:—

"Gallon, Bean, and Lumb, Leeds, exhibited a very useful and complete Mortising Machine, which was highly commended."

N.B.—The Patentees respectfully intimate that this Patent extends to, and comprises Machines for Mortising by Steam and other motive power, as well as by hand: and makers and vendors of, or parties buying or using Mortising Machines, *are cautioned against any infringement*, as the patent right will be strictly maintained.

MESSRS. TELFORD & TELFORD,
ORGAN BUILDERS.

Several new and second-hand FINGER & BARREL ORGANS, suitable for Church or Chamber, will be sold on very reasonable terms, to make room.

109, STEPHEN'S GREEN, DUBLIN.

BOOTH'S OLD ESTABLISHED

HYDE, SMITH, and LEWIS, Civil Engineers, Architects, Surveyors, etc., in a short Course of Instruction on moderate terms, including FIELD WORK and the use of the INSTRUMENTS. For Prospectuses, apply at the Offices, 24, Guilford-st., Russell-square.

N.B.—An Architectural, Engineering, and Mechanical Class for Architects, Builders, Engineers' sons, etc., on moderate terms, including instruction in Drawing, Coloring, Taking out Quantities, etc.

PURE AND BRILLIANT GAS LIGHT.
GAS IN COUNTRY MANSIONS.

IMPROVED PATENT HYDRO-CARBON GAS APPARATUS.

JOSHUA EDMUNDSON and Co. having the exclusive right to Manufacture and Sell this Gas Apparatus, call attention of the Public to this most valuable invention. It is peculiarly adapted for Lighting Gentlemen's Mansions, Colleges, Mills, Manufactories, Railway Stations, other Country Establishments, and Public Gas Works for Towns.

The Apparatus will produce more Gas from a ton of Coal than any other, and can be so arranged in the erection that the Cooking of an establishment, of whatever size, can be effected without expense, no fuel being required beyond that used in making the Gas.

Particulars as to price, size, scientific merit, etc., and the most satisfactory reference to parties for whom it has been erected in this country, will be given by

JOSHUA EDMUNDSON AND CO.,
34, 35, 36, CAPEL-STREET.

Estimates for all parts of the Kingdom given, free of expense.

Country Towns lighted at a very small cost.

Agents for Milner's Fireproof Safes.

Building Materials.

SAWING, PLANING, & MOULDING MILLS,

GREAT BRUNSWICK-STREET, DUBLIN,

MICHAEL MEADE,

HAVING completed the extensive Buildings and Machinery for Sawing, Planing, Moulding, Tenoning, Grooving, &c., Timbers at his new works, begs to inform his friends and the public that, in conjunction with his business as Builder, he has opened a new department for the sale of all descriptions of Materials used in Building. Timber, Deals, Laths, Prepared Flooring, Skirtings and Mouldings of all Sizes and Patterns always on hand. Doors, Sashes, Sash Frames, Shutters, Architraves, &c., made to order on the shortest notice and most reasonable terms. Being the *only* Manufactory of the kind in Dublin, it offers an advantage to persons Building which has not hitherto presented itself in this country.

From M. M.'s long practical experience in the working of all descriptions of Timber, persons requiring their Timber sawn or planed will find a great advantage in sending it to the above Mills.

THOMAS HENRY CARROLL,

70, SIR JOHN ROGERSON'S-QUAY,
(formerly occupied by Mr. James Fagan).

SCOTCH FREESTONE OF BEST QUALITY.

LEADBETTER, GOVAN, AND CO.,
HUNTERSHILL AND COLTMUIR QUARRIES,
BISHOPSBRIDGE, NEAR GLASGOW.
OFFICE IN GLASGOW—13, GORDON-ST.

STONES furnished, to any extent, in Blocks, Scantlings, or sawn up to any thickness, on the shortest notice, from the above extensive and well-known Quarries

This Stone is now largely used in Ireland for the ashlar fronts of Public Buildings, Noblemen's Mansions, cut stone dressings, interior columns and arches of churches, dressings of schools and villas, and is well adapted for every purpose to which cut stone is applied.

The facilities for shipping are unsurpassed, being connected by private railway with the Forth and Clyde Canal (within a few miles of the Clyde), where vessels of upwards of a hundred tons can be loaded in a few hours.

L., G., and Co., will be happy to furnish Architects, Builders, and others with list of prices at the Quarries, free on board, and freight to any port in the kingdom.

All orders promptly and carefully shipped.

OFFICE OF THE "CROWHILL, MILTON, AND KENMUIR QUARRY COMPANY (Limited)."

51, RENFIELD-STREET, GLASGOW.

HAVING entered upon a Lease of those extensive and well-known Quarries—Crowhill, Milton, and Kenmuir, near Bishopbriggs—long wrought by Mr. Wm. Neilson, parties desirous of supplying themselves with a first-class Rock, will be served promptly with any quantity, however large.

From our facilities for despatching materials by private Railway to Forth and Clyde Canal, Builders in Ireland will find this a cheap and ready mode of supplying themselves.

Any orders with which we may be favoured, shall receive our best attention.

WILLIAM GRAY, Secretary.

NOTE—We refer for sample of our stone to the new National Practising Schools, at Lower Gardiner-street, Dublin, and new Exchange, Dundalk.

BATH STONE OF BEST QUALITY.

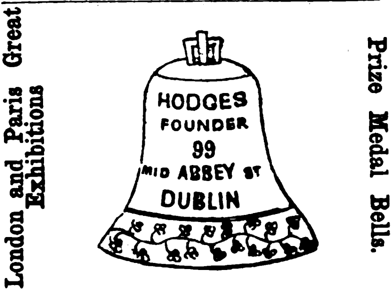
PICTOR AND SON, QUARRY PROPRIETORS and STONE MERCHANTS, BATH. List of Prices of Box Ground, and Corsham Down Stone (loaded in railway trucks at Box or Corsham Station), also cost of transit to all parts of the kingdom forwarded on application to Bath Freestone Works, Box, near Chippenham, Wilts. Dressings both plain and ornamental) prepared ready for fixing.) Vases, Tombs, Chimney-pieces, &c.



PATENT ASPHALTE ROOFING FELT.

ELLIS AND CO.,

MALONE MILLS, BELFAST,

Manufacturers of

PATENT ASPHALTE ROOFING, SHEETING, INODOROUS, AND BOILER FELTS.

Sole Agents in Dublin,

Messrs. CAROLIN AND EGAN, 20, EDEN-QUAY.

ASPHALTIC ROOFING FELT, a light, clean, economical, and durable roofing, price 1d. per square foot. Samples and instructions may be had gratis in answer to letters from any part addressed to MAURICE BROOKS, IRONMONGERY, GLASS, & ROOM PAPER WAREHOUSE, SACKVILLE-PLACE.

Building Ground, &c.

BUILDING GROUND at RATHGAR—between Kenilworth-square and Harold's-cross-road, near Roundtown—to be Let, at from 2s. to 3s. per Foot, Landed Estates Court Title, and 900 years' Lease. Apply to

BENTLEY AND SON,
110, GRAFTON-STREET, DUBLIN.

N.B.—A Quarry on the land, and bricks at half-price.

A FEW HALF-ACRE PLOTS at DUNDRUM for Detached Houses, within three minutes' walk of the Railway Station, to be Let cheap. Bricks and Stone on very moderate terms to parties building.

BENTLEY AND SON,
110, GRAFTON-STREET, DUBLIN.

BELMYRA, DUNDRUM, CO. DUBLIN.

TO CAPITALISTS, BUILDERS, & OTHERS.

MOST DESIRABLE BUILDING GROUND TO BE LET.—This Estate, containing 150 Acres, situated within half a mile of the Dundrum Railway Station, has been laid out in Lots for Building. The position is admitted to be the most beautiful in the environs of Dublin, and is particularly well circumstanced in every respect, commanding views of Killiney Hill, overlooking Mount Merrion, City and Bay of Dublin, &c.

A railway station in the centre of the estate is in contemplation, bringing it within ten minutes' drive per rail of Harcourt-street.

A map of the lands, showing them laid out in building lots, can be seen, and every information obtained, at the offices of Edward Henry Carson, C.E., Architect, &c., 25, Harcourt-street.

TO BUILDERS.—TO BE LET, in RATHGAR, on the Roundtown-road, about 500 Feet of BUILDING GROUND, 260 feet from front to rere, at 4s. per foot. Also, in Rathgar-avenue and Beauchamp-avenue, 2,000 feet, at 3s. per foot. Lease 999 years. The situation is unquestionably the best in the suburbs of Dublin. Apply to Dr. BEAUCHAMP, 115, BAGGOT-STREET; or to F. ARMSTRONG, Builder, BAGGOT-STREET.

NEWBRIDGE—BUILDING GROUND. Several Lots of BUILDING GROUND to be LET in the rising and rapidly improving town of NEWBRIDGE, in the County of Kildare, including a most eligible site reserved for an Hotel, which is very much required in the neighbourhood, and which would be sure to have immense business, there being nothing of the kind capable of meeting the requirements of the large Cavalry Garrison at Newbridge, the Camp on the Curragh, and the crowds who come in summer for the reviews and races on that grand plain.

Newbridge is a most central position for the meets of the Kildare Hounds (being itself one of them), and is close to the Station on the Great Southern and Western Railway, and one mile from the Curragh.

For further Particulars apply to Ponsonby Moore, Esq., Moorefield House, Newbridge.

IN CHANCERY.

Ffolliote
v.
Ffolliote.

TO be Let, on very reasonable terms, all that and those the Houses and Offices known as AIR LODGE, RATHMINES, containing every accommodation for a respectable family. Also the House No. 6, MARINO-CRESCENT, CLONTARF STRAND, having Parlours, Drawing-rooms, four best Bedrooms, Servants' Room, Water Closet, Kitchen, Pantry, &c.; Garden front and rere. These Houses are beautifully situated, commanding good views, with the advantage of the omnibus passing every half hour to and from Dublin. For terms apply to the Receiver, Edward Henry Carson, Esq., 25 Harcourt-street; or his Solicitor, Peter Lambert, Esq., 35, Lower Ormond-quay.

IBBOTSON'S IMPROVED OAK STAIN, for imparting to New Deal the appearance of Oak, and to New Oak the appearance of Antiquity.

It is about half the expense of paint, and is easily applied with a brush. Being an Oil Stain, it has the important advantage over all other stains of being impervious to wet. It produces a bright gloss, but if a high polish is required, the proper varnish can be applied. It requires no size or previous preparation of the wood.

The Stain (with the proper varnish, if required), of three shades—Light, Middle, and Dark—is sold in Bottles at 6d., 1s., and 2s. each, or by the Gallon, at 10s.

SOLE AGENTS—BOILEAU AND BOYD,
(Late John George Boileau and Co., Mary's-abbey)
92, BRIDE-STREET, DUBLIN.

NEW GAS REGULATOR AND PURIFIER.

MESSRS. DEFRIES & SONS, of London, having taken out a Patent for the above new Gas Burner, we beg to announce that we have just made arrangements with them for the special sale of it.

This artistic and complete Burner is the most economical ever introduced, and is the admiration of all scientific men, on account of the various qualities it possesses.

First—It purifies the Gas by filtration, and allows no more Gas to pass through the Burner than is absolutely required to give a full, clear, and brilliant light.

Second—It effectually checks all undue pressure, and does away with the unpleasant flickering and noise caused by the same.

Third—The interior is anti-corrosive, and is impossible to get out of order, and when once set right it will last for years.

Fourth—This Burner answers with any common nib, and is unerring in its operation.

Fifth—It can be fitted by the most inexperienced hand.

Sixth—Though last, not least—it effects a saving of 25 per cent.

Price 1s. 3d. each.

GREGG AND SON (Sole Agents),
LAMP MAKERS AND GAS FITTERS,
18, UPPER SACKVILLE-STREET, DUBLIN.

Important Improvements in Warming and Ventilating Churches, Chapels, Schools, Infirmaries, Wards of Hospitals, &c.

PIERCE'S UNRIVALLED

PYRO-PNEUMATIC FRESH-AIR WARMING AND VENTILATING STOVE-GRATE;

ALSO HIS CELEBRATED FRESH-AIR WARMING AND VENTILATING FIRE-LUMP GRATES.

Being the only Fresh-air Grates that are formed entirely of Fire-lump, without any heating surface of iron, having the open cheerful fire, producing Healthful Warmth, with self-acting and unceasing Ventilation, requiring no attention whatever when in use.

ILLUSTRATED CATALOGUE, with TESTIMONIALS, PRICES, and DIMENSIONS, will be furnished on application to the Inventor and Manufacturer,

WILLIAM PIERCE,
No. 5, JERMYN-STREET, REGENT-STREET, LONDON.

HIBERNIAN MILLS, KILMAINHAM.

Putty,
Whiteing,
John's Cement,
Mastic,
Coal Dust.

SAMUEL DAVIS, MANUFACTURER,
AND AT
37 AND 138, ABBEY-STREET.

IMPERISHABLE TESSELATED PAVEMENTS.—H. SIBTHORPE AND SON, Agents to Maw and Co., are prepared to supply Designs for Floors of Churches, Conservatories, Entrance Halls, and Passages, with proper Workmen to lay them in any part of Ireland.

Various specimens may be seen at their Warerooms,
11 AND 12, CORK-HILL, DUBLIN.

FOR SALE, at the WATERFORD SHIP YARD, Ferrybank, a very superior highly finished

NEW STEAM ENGINE,

Estimated at about 40 Horse Combined Power, which highly improved construction is admitted to be the most economical in the consumption of Fuel. Condensing Cylinder, 21 inches diameter, with 5 feet stroke. High Pressure Cylinder, 13½ inches diameter, with 2½ feet stroke.

This Engine has been built with the best materials and workmanship, regardless of expense, and is particularly well adapted for a Flour (or other) Mill. The very great falling off of late years in the supply of water-power renders it almost indispensable that auxiliary steam power should be attached to Flour Mills to ensure constant working of the establishment during the period of scarcity of water.

Further particulars can be had by application at the Ship Yard.

ROBERT MACLAREN & CO.,
EGLINTON FOUNDRY, GLASGOW,

Manufacturers of all sizes of CAST-IRON MAIN PIPES, for Gas or Water, by an IMPROVED PATENT.
GENERAL IRON FOUNDERS, GAS ENGINEERS, and WROUGHT-IRON TUBE MAKERS.

on TUESDAY, the 3rd of APRIL,
at Twelve o'clock,

20,000	feet of	Honduras Mahogany, in Log and Plank.
5,000	„	St. Domingo Table Wood.
5,000	„	Havanna and Pencil Cedar.
5,000	„	St. Domingo Veneers.
30,000	„	Oak, Ash, and Birch.

Pine in Log and Plank. Several Lots of Deals. The above contain a large proportion of Seasoned Wood, well worth the attention of the Trade. Terms Cash £25 and under; exceeding, approved Bills at four months. For further particulars apply to

J. BARCROFT, Broker and Measurer,
42, Great Brunswick-street.

Auctions, Sales, &c.

AUCTION OF WOOD GOODS.

JOHN MARTIN AND SON
WILL OFFER BY AUCTION,
ON THURSDAY, 19th APRIL, 1860,
AT THEIR STORES, NORTH WALL,

A large assortment of Timber, &c., from their present large Stock, consisting of

Spruce Deals,
Pine do.
Red do.
Crown Memel,
2nd quality do.
Red Pine,
White Pine, and
Sundswall Timber;
Also

A Cargo of SPRUCE DEALS, &c., per "Empire Queen," now on the way from St. John's, N.B.

JAFFRAY BARCROFT, Broker and Measurer.
North-wall, Dublin, 24th March, 1860.

ON Wednesday next, the 4th April, at Eleven o'Clock precisely, on the Quay, east side of the Huskisson Dock, Liverpool,

284 Logs Honduras MAHOGANY,
now landing ex Isaac Webb.

4 Logs Honduras MAHOGANY,
ex Constitution. Apply to A. Glassford, Esq., merchant.

In the Wood Sales Sheds, Brunswick and Toxteth Docks,

50 Curls Honduras MAHOGANY,
now landing ex Mary Worrall, from Belize. Apply to A. Glassford, Esq., merchant.

247 Logs Mexican BAYWOOD,
being the cargo now landing ex Mary Miller, from Minatitlan.

On account of the importers.

153 Logs Cuba MAHOGANY,
77 Logs Havanah CEDAR,
1500 LANCEWOOD SPARS,
6 Tons COCUSWOOD,
now landing ex Helena, from Manzanilla. Apply to Messrs. B. Hall and Co., and to Henry Williams, Esq., merchants.

96 Planks Italian WALNUTWOOD,
ex Sicilian, from Ancona. Apply to Messrs. Kohn, Speyer, and Co., merchants.

146 Planks Italian WALNUTWOOD,
ex Venetian, from Ancona.

On account of the importers.

To which will be added various Parcels of Bird-eyed MAPLE, Pencil CEDAR, &c.

EDWARD CHALONER, Wood Broker & Measurer,
6, East Side Queen's Dock, Liverpool.

MAHOGANY AND OTHER WOODS.

J. BARCROFT, Broker and Measurer, 42A, GREAT BRUNSWICK-STREET, begs leave to inform the Trade that the well assorted and seasoned stock of the late Joseph Booth, of 35, Golden-lane, will be SOLD by AUCTION, on TUESDAY, the 3rd of April, at 12 o'clock.

J. BARCROFT, Broker and Measurer, 42A, GREAT BRUNSWICK-STREET, begs leave to inform the Trade that he will have a very extensive SALE of TIMBER and DEALS, for Messrs. John Martin and Son, North-wall, on THURSDAY, the 19th of April, at 12 o'clock.

J. BARCROFT, Broker and Measurer, 42A, GREAT BRUNSWICK-STREET, begs leave to inform the Trade that he is now measuring a prime Cargo of MEMEL TIMBER, ex Oello, for account of Mr. JOSEPH KELLY, SIR JOHN ROGERSON'S QUAY.

J. BARCROFT, Broker and Measurer, 42A, GREAT BRUNSWICK-STREET, begs leave to inform the Trade, and others wanting to purchase at any of the above sales, and who cannot attend, that he will do so at a small commission.

J. BARCROFT, Broker and Measurer, 42A, GREAT BRUNSWICK-STREET, begs leave to inform the Trade that any Timber that has been measured by him he will inspect for the purchaser, and certify as to its correctness, free of any expense; and in case it has not been measured, at a charge of 8d. per ton. This, in many instances, would be a saving of 10s. per ton.

J. BARCROFT, Broker and Measurer, 42A, GREAT BRUNSWICK-STREET, begs leave to inform the Owners of Woods that he Measures and Values every description of Native Timber, and has at present a very extensive Wood for Sale.

The Dublin Builder.

Vol. II.—No. 17.

APPOINTMENTS AND *DIS*-APPOINTMENTS.

"BLESSED are they that expect nothing, for they shall not be disappointed," is so proverbially applicable to our individual self, as regards the two engrossing and still doubtful questions before the professional world—viz., the vacancies in the architectship of the Ecclesiastical Commission, and of the intended new Church of St. Andrew, respectively—that we are enabled the more dispassionately to review both in all their bearings. Scarcely were the cold remains of the late amiable and respected architect to the Board—Mr. Joseph Welland—laid in their last home, when gossip, with its many tongues, clattered about his successor. Rumours, as rife with improbabilities, and inconsistencies of supposition as the reverse, were circulated industriously; and letters, some of which, *at request*, we now publish—though without identifying ourselves with the authors' statements—were addressed to the morning journals on the subject. Architecturally viewing the nature of the appointment, it certainly ranks as number two in position of influence upon our national artistic advancement, and, in one regard, may possibly with some justice contest the palm with the official of a more extensive establishment associated with governmental constructions. If there be one class of edifices which more than another denotes a people's backwardness or progress, as the case may be, in civilization, it is the "Ecclesiastical;" *par example*, the temples of Egypt, Greece, and other countries, the glorious Christian piles of the European continent, and England's venerable cathedrals, with vaulted aisles and silent pointing spires, speak, "more than words could tell," *a history*, and more than ponderous tomes of antique records could divulge. Hence, in a national spirit, if not in a numerical, the capabilities of the successor to this post must be regarded, by the Commissioners especially, and will be by the discriminating section of the public. Whatever the result may be, clamour infallibly will arise, not amongst the professional competitors, whose abilities might entitle them to the office—for gentlemen would contemn the course—but with those garrulous, useless, busy-bodies, who meddle, and talk, and write for the sake of notoriety, without one particle of sincere feeling of interest in the issue. The Commissioners, however, confident of their own good faith, in selecting "according to the best of their judgment," will "lay the flattering unction to their soul" that they have fulfilled their task judiciously, and shrink not from expression of opinion. Difficulties beset their path—claims from old associates, prior to the extinction of the Board of First Fruits, and backed by influential archiepiscopal interest, and weighty voices of distinguished Privy Councillors are—as we learn—being earnestly pressed; again, important active services, rendered to the Commissioners in the department during a lengthened period, are suggested for consideration; testimonials, numerous and voluminous, accompany a host of other claims, from each province and across the Channel; and lastly, the able and faithful services of "the father" are sought to be recompensed in the person of "the son," his toiling partner and representative, intimately acquainted with the routine and duties of the office, and competent, as we are informed, to fulfil them with hereditary ability. How the Commissioners *will* decide, it is not for us to judge; but we confess to a presentiment that an old and respected member of the profession of the former class may establish his rights to a preference, while the latter—"the hereditary claim"—will, by arrangement, not be overlooked. Surely some of the candidates for this office could not possibly have been guided by sincerity in expectation of the result, either to submit their names or their qualifications to the Board? if so, we rather sympathise with their imbecility than otherwise. Had space permitted we should have enlarged on this subject, but are compelled to complete this portion of our article by publishing the correspondence in question.

The following has appeared in the morning and other local journals on this topic:—

An "Architect" writing to the *Irish Times* says—

> "Several architects of high standing and character are already in the field, and from the numbers and respectability of those looking for the office, it is evident that the great difficulty will be to select the *best* man out of so many. The profession in general (not only in Dublin, but also in Belfast and Cork) seems to be on the *qui vive*, being naturally anxious that a post of such honour, and one which exercises so great an influence on the architectural taste of the country at large, should be occupied by some member of the profession who will help to improve the style of ecclesiastical architecture throughout Ireland, and be an able and worthy successor of him who so long and so creditably filled the post. The clergy, also, from one end of Ireland to the other, must feel a deep interest in the matter. Nor should the public be indifferent in the selection, for there is no architectural position in Ireland whose occupier can more largely extend and cultivate pure architectural taste. As far as my connection with the profession enables me to judge, there seems to be but one feeling among them—that of deep regret for the loss of Mr. Welland, and a hope that in whatever arrangement the Commissioners may make, they will not overlook the decided claim of his son, who has assisted his father in this office for some years, and that the person who may be selected, in answer to the advertisement of the Commissioners (whether in conjunction with Mr. Welland or not), should be one fitted by education, talent, and prestige, to advance the interests and uphold the respectability of the profession."

Another to the Editor of the *Dublin Evening Mail* writes—

> "Sir—As many of my professional brethren are no doubt looking with anxiety to the issue of their applications to the Ecclesiastical Commissioners for the appointment of architect to their board, I consider it right to state that I am credibly informed that, even before the Commissioners' advertisements appeared, the appointment was virtually arranged, and that the person likely to be nominated is not a professional architect, and only served a few years to a country builder and measurer, and is at present a junior inspector in the office. If such an appointment should be seriously contemplated, nothing can show more clearly the necessity there exists for architects to unite to protest against this and other like infringements, and to uphold the character of the profession."

A "Churchman" to the Editor of the *Irish Times*, remarking that "the clergy must feel a deep interest in the matter," and that "the public cannot be indifferent in the selection," says—

> "I, as one of this great body, ask your permission to offer the following observations on the question:—Who should succeed the late Mr. Welland?—that is, who, to again quote your correspondent's words, is to be the "able and worthy successor of him who so long and so creditably filled the post?" It would, indeed, be desirable that his successor should be really an architect of "high standing and character," and also, let me say, a Churchman, and, if possible, in advance of Mr. Welland in the knowledge and development of ecclesiastical architecture. But this is precluded by the absurd condition prescribed by the Commissioners—that of requiring a total devotedness of time to their service—absurd, because of the miserable equivalent offered in the way of salary; to wit, £600. To obtain what they require the salary should be, at least, £1,000. For less than this no architect of eminence or character would forego his private practice. Hence it is that many who, at the first blush, did appear as candidates, have withdrawn, and others to whom public opinion pointed do not appear. The Commissioners have wisely delayed making a selection. They are in a difficulty. Under the circumstances above alluded to, they can hardly have before them the name of one single person who, from standing in the profession, as regards Ireland, or from known ability in any branch of art, should be appointed to the vacant chair. Their wisdom is, that in this their difficulty they delay. Delay will tire us—the public. We will cease to think, consequently to speak or write on the subject; and, after a sufficiently decent interval has elapsed, to have led us to imagine that the Chancellor and the Episcopal Commissioners had considered and agreed to the fact, we will open our eyes in wonder some fine morning as we read—what it is whispered has already been decided on—that Woodscrew Gimlet, carpenter, has been appointed architect to the Ecclesiastical Commissioners, vice Joseph Welland, architect, deceased. I may be wrong in my idea, but the conviction presses strongly on my mind, that in this appointment, I, as an individual, have a personal interest, position, and right. As a churchman, I claim to have a right in the possession of the house in which I worship—a right more superior than that I have in the house in which I reside, because of its more sacred character—and therefore I cannot be indifferent to the appointment which may throw the care of that house into hands unworthy to receive it. I would rather—and having spoken to many on the subject, am convinced, mine is the opinion of no small section of the church-going public—I would rather than that this evil should occur that no appointment at all was made, save what may be necessary to carry on the current business of the establishment, and that church-building parishes, of which, through God's goodness, we may hope for many, would only be required to look to the Commissioners for pecuniary assistance, and be, in matters of taste, left, as in the case of St. Andrew's, to the exercise of their own judgment."

The personal references embodied in these two last letters is, to say the least, unwise, and probably erroneously anticipatory.

The Committee entrusted with the carrying out of St. Andrew's new Church have opened their proceedings by at least a *semblance* of good faith, in permitting the competition drawings to be exhibited. If the course be suggested by sincerity, they simultaneously attain the double object, of additional assistance to their own counsels in courting public opinion, and, by allowing the authors the fullest publicity of their relative merits, they contribute a certain amount of gratification to their pardonable pride and ambition, though otherwise doomed to be *dis*appointed. Let us hope, therefore, for the sake of those immediately interested, and for the public at large, that it is so! Each author is represented by a motto, and, although to the gossippers in the gallery and to ourselves the paternity of each design is familiar, we nevertheless are reminded by a feeling of good taste and justice to preserve the *incognito*. In our judgment, the question of the *noblest* design and the *handsomest* drawing displayed has been indisputably solved by the authors of monogram "Shamrock in a circle." We have never seen at any exhibition, or in reality, a more beautiful conception for a parochial church. In this opinion we venture to add that Committee, competitors, and the public unite. But the authors frankly confess that it cannot, as shown, be executed for the money; what, then, is the alternative? Is it true that the Committee, as we are informed, called for modified drawings of the design—denuded of its beauties, curtailed in its proportions, the mere shadow of its former self—thereby giving a preference over those competitors who scrupulously adhered to the instructions, and give excellent, though not so costly or magnificent, designs, guaranteed not to exceed the stipulated amount? If so, we anticipate, to use our adopted term, no moderate display of *dis*appointment by the remaining authors of the favoured *six*, who, as nearly as we learn, stand in the following order: monogram, "Shamrock in a circle;" "Templa quam delecta;" "In fide et in bello fortis;" "Dum spiro spero;" "Excelsior;" and "Donec templa refeceris."

In the present stage of the matter we abstain from prejudicing the result, which we anxiously await. At page 247 may be found a more detailed notice of the designs.

NOTES ON THE ROUND TOWER CONTROVERSY.*

(Continued from page 231.)

Having thus given instances of the use of the terms locally applied to these remarkable structures, I would next direct attention to the mis-application of the word *Cloichteach*. I have before remarked the great importance attached by Dr. Petrie to the assumption, that this term, used in a certain number of places in the Irish Annals, signifies "a Round Tower belfry"—we shall see with what probability. The term is compounded of two words, *cloich*, a stone, and *teach*, a house. The term, then, *cloichteach*, would read "stone house," to distinguish a building erected of stone from those in general use, formed of wattles, logs, or built of sods,—such as were not only the private houses and cabins of the ancient Irish, but also a great many churches and oratories in the early ages of Christianity, not merely in Ireland, but in England. And, that buildings constructed of stone, whether churches or otherwise, should be distinguished from those composed of other materials, is extremely probable and natural: indeed, in our native annals they are so distinguished. Thus, the term *damliag* applied to a church, is exactly of the same meaning as *cloichteach*, from *daimh*, a house, a church, and *liag*, a stone. The compound name is given in O'Reilly's Irish dictionary, *daimhliag*, a church of stone.

The native annalists use a similar expression to designate wooden churches and oratories; the compound term, *dairtheach*, *duirthech*, &c., from *dair*, an oak, and *teach*, a house, "the oak house, or house of wood" [see Dr. Petrie's work, page 342]. So that we have here terms profusely used by our native historians, to designate religious structures by the materials of which they were composed; and we must, therefore, in analogy with these other terms, take *cloichteach* to mean stone house, and not a round tower belfry, as it expresses neither form, height, nor use.

That there were belfries at a comparatively early period in Ireland I will not by any means dispute; and that they were sometimes called *clogteach* is probable enough; and that the ancient Round Towers were turned into belfries on the introduction of church bells into Ireland, is more than likely; but I do dispute that there were belfries—that is, buildings specially erected for hanging church bells in—before the tenth century.

Indeed, the first notice that Dr. Petrie has been able to produce, of what he designates a round-tower belfry, is in the middle of the tenth century, and is, as follows, from Dr. O'Donovan's translation of the "Annals of the Four Masters":—

"A.D. 948. The Cloichteach of Slane was burned by the foreigners, with its full of relics and distinguished persons," &c.

Dr. Petrie maintains that this was a round tower. What is there in the term to designate its circular form, or its tower-like elevation? But the circumstance itself is very unlikely to have happened to, or in, a round tower. In the first place, there is not, and never was, in memory or tradition, a round tower at Slane; and secondly, how could a round tower be burned? It is a circular edifice of stone, with massive wall, stone roof, a small doorway at a considerable elevation from the ground, and a few small apertures for windows at a much greater height. What was there to burn? "The wooden floors and doors," suggests Dr. Petrie. But what evidence have we that the floors, *if any*, were of wood? None. We have not a scintilla of evidence that they were of any material but stone, if we can take as evidence the fact, that the only original remaining floors are of stone. Four of these floors remain in existence. Portions of two arched floors are at present to be seen in the Castledermot example; the first, of which nearly two-thirds exist, is about fifteen feet above the sill of doorway; of the second—which is about fifteen feet higher up—about one-third remains. They are constructed of rubble, cemented together by a most powerful mortar of extreme hardness; they have a rise of about thirteen inches in the centre, and the arch was about a foot thick; but its strength evidently depended more upon the solidifying property of the mortar than upon the disposition of the stones in the arch. These arches spring from projecting string-courses, and here we may see what the internal string-courses of the towers were intended for. These floors were destroyed for the *purpose of getting up the bells*, when this tower was converted into a belfry. The tower of Kinneigh, County Cork, has a floor formed of slabs of stone which "tail" into the wall. At Meeleck, County Galway, is an interesting example of one of these arched floors, given in Mr. Wilkinson's *Practical Geology and Ancient Architecture of Ireland*. The ancient Irish, who erected great stone forts, with stone lintelled gates and passages; who constructed underground chambers domed with stone, and intricate passages lintelled with the same material; who on the southern and western coasts constructed numerous buildings entirely of stone to the apex of the roof, on plans embracing the rectangle, square, circle, ellipsis, quadrant, and the form of the human eye; and who subsequently built their churches with stone roofs: such a people, I say, were not likely to put wooden floors in their stone-walled and stone-roofed towers. Indeed it is certain that many of the towers had no floors, as we have instances of towers without floors, string-courses, off-sets, joist-holes, or any provision for floors.

Under such circumstances, we must reduce the conflagration to that of the door itself, which would not make enough of a blaze to justify the annalist in the strength of his language. But if we consider the historian to mean here the stone house, or church of Slane, all difficulty vanishes. The sacred edifice has been in all ages, and among all people—Pagans as well as Christians—the refuge in time of public calamity and danger: thither they fled to be under the special protection of the Deity. The Church of Slane alone could contain the numbers of persons stated to have taken refuge. The roof, altars, doors, fittings, &c., offered alone sufficient food for the flames of a conflagration, attended with such results.

The next notice is, A.D. 995, as follows:—"A.D. 995—Ardmacha [Armagh] was burnt by lightning, both houses, churches, and *cloichtheaca* and its *Fidh-neimhed* [sacred wood], with all destruction." That the word does not refer to a round tower is evident to the simplest understanding; for how could a hollow stone pillar, stone to the pinnacle, be burned by lightning? Yet, upon such absurdities has Dr. Petrie erected his Christian theory. The appellation must refer to some other class of religious structure, connected with the large ecclesiastical establishment at Armagh. But, supposing that the word does mean a bell-house, or belfry, it does not imply that it was a round tower; it is very probable that wooden belfries were used here, as on the Continent and in England, at that and much later periods. It is absurd to suppose that where we had churches of wood we should erect belfries of stone 120 feet high, and almost as durable as pyramids. There is no round tower at present in Armagh, nor has there been in any living memory. At A.D. 1020 of the same "Annals," we have the burning of the *Cloichteach* of Armagh with its bells. It is utterly absurd to suppose that these repetitions of conflagrations refer to any but structures of a fragile and inflammable construction. The above passage records, I believe, the first mention of church bells in Ireland. Bells were in use previously, but they were hand-bells, used in church services as among the Egyptians, Romans, and Hindoos. There has been a great deal of archæological nonsense written about these bells, and a great many idle and superstitious legends recorded of them, and gravely retailed by a certain class of modern antiquaries. I believe that about this period bells to call persons to public worship came into use, though still confined to churches of eminence. As I have before stated, it is only reasonable to infer that the ancient towers were used as belfries (as indeed some are to this day) in those places where they existed, and that in other places appropriate bell-turrets, or bell-cots, were erected.

It is probable many of our earliest belfries were of wood; ancient ones of stone are also in existence, some of considerable antiquity. A triangular-headed bell-cot is found over the west gable of the ancient church of Roscrea, an example of early Romanesque. A similar one exists over the west gable of the very ancient church of Monainchs. A large triple bell-cot is found at Donoughmore, in close proximity to the Round Tower. The example at Roscrea is also within a few yards of the Round Tower. In a great many instances, belfries are found on churches of the thirteenth, fourteenth, and fifteenth centuries, in close proximity to Round Towers; an evident proof that the towers were not used as belfries, or considered suitable for that purpose. Square belfries of a remote antiquity are also found in Ireland.

---

* By Richard Rolt Brash. From the "Ulster Journal of Archæology."

On Innis-clothran Island, in Lough Ree, is one as old as the tenth or eleventh century. A very ancient one is erected over the west gable of the little church of Cloghereen, near Killarney. Cormac's chapel, at Cashel, was commenced about the year 1100; it was consecrated in A.D. 1134. It is a small building, consisting of a nave and chancel, showing evidently that the magnificent Round Tower standing within twenty yards, and looking down majestically upon these things of yesterday, was not considered suitable for a belfry, or held in any particular veneration.

The remaining notices referring to "cloichteach," in the "Annals," are eleven, being altogether fourteen, commencing at the year 948, and extending to 1238. Of the above number of places thus noticed, Round Towers exist but at five. It is also remarkable that six notices record the burning of a "cloichteach," which I have shown to be impossible to a Round Tower. Two of these notices occur, one in the middle, and the other at the close of the tenth century; the rest occur in the eleventh and twelfth centuries, at a period when it is well known extensive monasteries and large abbey churches were erected such as Boyle, Jerpoint, Dunbrody, Ballintubber, Cong, Corcumroe, and others. These edifices are planned on the same principles as the Continental churches of the same period, and of dimensions not far short; consisting of nave, aisles, transepts, chancel, and numerous chapels, with massive square belfries over the intersection of the nave, transepts, and chancel.

The Irish language gives us unmistakeable terms both for bells and belfries; thus we have *Clocc*, *Clog*, a bell; *Clogachd*, *Clogas*, a belfry. If the Irish annalists, in the passages quoted by Dr. Petrie, intended to have expressed "belfry," they would surely have used some of the above terms, and not the word *Cloichteach*, which I have already shown means "stone house." And what do I find? Why, that the only notice of an authenticated belfry, and which is still in existence, and can be identified, occurs in the "Annals of the Four Masters," at A.D. 1584, where the *square* belfry of the abbey church of Quin, in the county of Clare, is called a *Cloccas*. The learned translator, in a note to the passage, says:—

"*The clocus of Cuinnche*, *i.e.*, the belfry of Quin. The word 'clogas' is *usually* applied to a round tower belfry detached from the church; but it is here evidently applied to the square tower of the great abbey of Quin, still remaining." How can the translator say "*usually* applied," when in the entire "Annals," there is not a single instance of the use of the term, except in this one instance, where it is used to designate a belfry, which happens to be a square one of the fourteenth century?

According to Dr. Petrie, the first notice we have of the erection of a belfry is in the year 965. The passage he quotes from the "Chronicon Scotorum," has reference to the erection of a "cloigteach," at Tomgraney: the word has an affinity to, and is derived from "*clog*," a bell; but whether the belfry, or bell-house was a round or square tower, or whether it was a tower at all, is very problematical. The only tower at present in existence at Tomgraney is a massive square one adjoining the church; but there formerly existed an ancient bell-cot on the west gable of this truly primitive building. Dr. Petrie asserts that a tower was in existence at Tomgraney forty years ago.

Now, I visited Tomgraney in the year 1852, accompanied by that eminent and laborious antiquary, Mr. John Windele, of Cork. We made the strictest inquiry respecting this fabled tower; indeed, to satisfy ourselves on this point was one of the principal objects of our visit; we procured the following evidence:—Peter Byrne, woodranger, aged over sixty years, "remembers the old church from his infancy, certainly over fifty years. Never saw a steeple or any portion of a steeple here; never saw any building like the round tower on Holy Island."[*]

Simon Hickey, an intelligent old man, and a Protestant, frequenting Tomgraney church all his life-time, stated "He was eighty-six years old, and never saw a belfry, round or square; never saw a building like the tower on Holy Island at Tuam (Tomgraney); it could not have been there unknown to him. Never heard the old people (his parents) say there was. He remembers a belfry on the west gable of the church, but it has been down for many years; and there has been no bell in it since his time."

That the word "cloichteach," does not *always* mean a *round* tower, is, indeed, admitted by Dr. Petrie himself, for, in quoting the erection of one at Annadown, A.D. 1238, he says,—"As there is no belfry now remaining at Annadown, it may be uncertain whether this 'cloichteach' was of the usual ancient round form, or of the quadrangular shape, and connected with the church, as generally adopted in Ireland at the period of the Anglo-Norman invasion." If, then, there is any uncertainty as to the meaning of the term in this case, every other is open to the same objection; and I certainly, for one, am not prepared to accept a theory based upon so flimsy a foundation.

The characteristics of the belfries belonging to parochial and monastic churches in Ireland, in the thirteenth century, are too well known to every student of Irish mediæval architecture, to admit the probability of a *round tower belfry* being erected at an era when church architecture received such an impetus, as it did at that period from the influx of the Anglo-Saxon invaders, and from the more immediate connection of the Irish church with that of Rome. From the year 1200 to 1260, were erected the following monastic houses:—Drogheda, Newtown, Lorha, Kilkenny, Youghal, Trim, Ballybeg, Buttevant, Athenry, Kildare. These buildings were erected in the first Pointed style; their towers were lofty, square, battlemented structures, poised upon arches between the nave and the chancel. The churches were from 140 to 200 feet in length, consisting of a nave with, and often without, aisles, a chancel, generally but one transept, with side chapels. The conventual buildings consisted of the usual domestic offices, surrounding a cloister court, and were very extensive, as the ample ruins still existing testify.

Before I conclude, I would wish to notice one singular fact. It may appear strange to the English reader that the Irish had no word to express a lofty and tower-like object; but such is not the case: the word *Tuir* s.m., signifies a tower, or castle. *Tor* s.m., a tower, a castle, spire, steeple. Welsh *twr*. [O'Reilly's Dictionary; see also O'Brien's.] It is, therefore, very singular, if the passages before quoted alluded to the Round Towers, that so appropriate a designation in every respect was not adopted. The word is frequently used in the "Annals of the Four Masters": thus, at A.M. 3066, mention is made of the demolition of the *Tuir* [tower] of Conain; and again, at A.D. 991, mention is made of "Taidhg of the *Tuir*." Dr. O'Donovan, in every case, translates it "Tower."

THE DESIGNS FOR ST. ANDREW'S CHURCH.

FOURTEEN competitors entered the lists, and, by arrangement of the committee, their designs, comprising 115 drawings, have been exhibited in an apartment admirably adapted for the purpose in the Royal Irish Institution, College-street. Commencing at the entrance doorway, and pursuing our course to the right, we view them *seriatim*, but must premise that all are Gothic—some very questionable indeed, and exciting sympathy for the authors' assumption of claim to consideration from an intelligent committee—also that there is a striking similarity in the arrangements of the plans *generally*, that all the authors are represented by mottoes, and, as a whole, that the exhibition is most creditable.

First impressions are said to be lasting, but we question if they are always favourable; indeed they are not so as regards the designs of "Finem respice," from whom we would have expected something better. "Fides," by a hand comparatively unknown, has its merits and demerits likewise. The perspectives are effectively etched, but the roofing timbers and the tower—too naked in the stages—with a squat spire, act detrimentally. The plan of this set is an oblong. It seems to be a pity that the author of "My Design," who is evidently of an aspiring disposition, did not cause his photograph to be affixed to each of his eight elaborate drawings, that his immortality might be the more perfect. His motto, "Except the Lord build the house, their labour is but lost that build it," suggests an amendment in his case which we prefer leaving to the *admiring* beholders to supply. "Resurgam"—either one or two shall we call him? for there are three, by a strange coincidence, but the third is a mere schoolboy (we hope) attempt at a something—has some excellent drawings, and his touches throughout proclaim a skilful hand. The same objection, however, applies to his spire as to that of "Fides," being abruptly terminated, and an unsuccessful imitation of a well-known example. His plan is cruciform, with nave, 98 feet by 24 feet; aisles, 52 feet by 13 feet 6 inches; transepts, apsidal, chancel, &c.; and variety of colour is sought to be introduced into the elevation by different materials. The author of monogram T in a circle displays ability, and his line engraving imitation perspective is very creditable, but the depressed transept roof and treatment of upper part of tower, are strikingly defective. We must not, however, put a young aspirant with ability out of conceit, and we freely admit that he has reason to congratulate himself. "Resurgam" occupies next compartment, but as already stated, "his room would be preferable to his company." "Delta" is not as happy in his design for this as in some of his previously-executed works, many of his features being too much cut up. His style, however, has some merit, but requires an amount of care in the treatment certainly not apparent here. The designs under motto "In fide et in bello fortis" are both good, but that estimated at £9,600 decidedly preferably to that at £10,760, though a less commanding spire—the treatment of which is nevertheless admirable—is provided for to save expense. The plan for both is substantially the same, comprising nave, 96ft by 26ft. 8in.; aisles, (breadth in clear of outer wall, 60ft.); transepts, 92ft. by 43ft 6in.; apsidal chancel, 88ft. by 26ft. 6in., &c. &c. About 1,003 sittings are provided, and the general arrangements are excellent. The author may congratulate himself on producing an admirable design throughout, and which is effectually developed by an able artistic hand, which though not practising at home is nothing less meritorious. "Templa quam delecta." This plan is cruciform, with apsidal chancel, south chancel, aisles, nave, and transepts. The dimensions are 137ft. 6in., by breadth across transept 77ft., and from aisle to aisle walls 55ft.; breadth of nave, chancel, and transepts, 27ft. 6in. The tower and spire—220 feet to vane—are placed at north side of the chancel, exactly opposite to Church-lane. The transepts have elaborate 6-light windows, of great height, on the three sides. The peculiar feature would seem to be the absence of any constructional chancel,—the total length being divided into ten bays of equal width, of which four are occupied by the chancel, and distinguished only by great richness of decoration, two by the transepts, and four by the nave and the unbroken roof of high pitch (a tie-beam with semicircular trusses). The shafts of the chancel are Galway marble, and the caps, strings, and roof principals are more elaborate than the nave. The entrances are by a tower porch and north porch, with cloister, occupying three bays of the nave in length, and by a west door. Eight drawings, cleverly wrought, but requiring close investigation to become acquainted with the style and features, are displayed under the motto, "Donec templa refeceris." The plan is a simple oblong, with semi-octagonal chancel, and aisles serving as passage-ways internally to the structure. The perspective accompanying this set is certainly the most striking pictorial effort in the exhibition, revealing the style of a well-known hand, an architectural artist, distinguished for his richness and warmth of colouring, with which, though fully admitting the artist's excellence in his style, we are not quite enamoured. A certain Byzantine shop front in Suffolk-street is introduced in perspective in the foreground, and contributes an effect to the picture not to be found in the original. We are slow to believe that this is amongst the most successful designs of the authors, and expecting great things, are confessedly much disappointed. The authors of monogram "Shamrock in a circle," display twelve drawings, including three external perspectives, which for beauty of design and execution are pre-eminent, and excite universal admiration. In the plan there are some peculiarities of proportion, the nave being only 82 feet in length by 29 in width, or about one third; aisles 25 feet in width; transepts, 100 feet by 25 feet; the chancel is apsidal. A cloister porch, with passage to the parish burial ground, a lych gate, some imaginary buildings (we presume schools) constitute, together with the exquisite features of the design, an uncommonly handsome picture. Divested even of its elaborate tracery, its flying buttresses, crooked pinnacles, &c., the outline and general features would still be most meritorious, and to realise their justly cherished hopes of success, and keep within or even near the prescribed mark, the authors would find this indispensable. Passing to the next – another "Resurgam"—the feasted eye labours under a difficulty to discriminate impartially, but must see merit here, and acknowledge it. On six sheets are plans and elevations, including a perspective. The plan is cruciform, with transepts and apsidal chancel: the tower and spire afford an excellent study, and the whole is a clever composition, such, indeed, as we *should* expect. In "Excelsior's" ten drawings are visible the hands of the architect and the artist; his perspective, though less pretentious than others, commands admiration for its intrinsic excellence; and his plan, which is oblong, with nave, aisles, apsidal choir, octagonal vestry, robing room, &c., has an additional aisle at part of flank adjoining the vestry. Next, and "though last not least," certainly is "Dum spiro spero" ("Dum spiro aspiro" would have seemed equally appropriate), next the entrance doorway, and eight drawings including some external and internal perspectives, admirably, though somewhat too warmly, tinted, comprise the set. The plan is cruciform, with nave 92ft. by 27ft.; aisles, 13ft. 6in. in width; transepts, 89ft. across; chancel, sacrarium, north and south chapels, vestry, tower (baptistry) &c. Coloured marble columns are introduced into the interior view, and the various features in the elevation, including a tower and spire some 200 feet high, present a most creditable and well-studied composition. Elsewhere in this number will be found further remarks upon this competition.

---

[*] Inniscaltra, in Lough Derg, on which there is a fine Round Tower.

THE SPRING SHOW, ROYAL DUBLIN SOCIETY.

IN noticing this exhibition we must necessarily—to keep within our province—abstain from referring to many objects of interest to ourselves personally, as well as to the general public, and pass at once to the stands of the manufacturers. Messrs. Hodges and Son, of Westmoreland-street, Edmundson and Co., of Capel-street, John Maguire, of Dawson-street, and Saunders, of Dame-street, ironmongers, displayed a quantity of goods in their line which, for excellence of workmanship and variety of design, could not be surpassed. Hodges' prize cattle steaming apparatus. Edmundson's model of their patent apparatus now so extensively adopted for the supply of gas in gentlemen's mansions, &c., their washing machines and fire-proof safes (Milner's patent), Maguire's field gates and stoves (Gurney's patent), attracted much interest. Musgrave, Brothers, Belfast, occupied a very extensive area, and their stable fittings were peculiarly noteworthy, showing many recent and important improvements in construction; as also were their combustion stoves, their entrance gates and piers, their cast-iron portable summer-houses, smoking bowers, &c. The manufactures and designs of this enterprising firm will stand the test of comparison with those of any in the kingdom.

Booth, Brothers, of 8, Upper Stephen-street, sustained most creditably the old-established reputation of their name in the manufacture of mechanical appliances and requisites. We should specially notice their improved apparatus for erecting wire fence, their American patent wrench and felling axe, their grindstones on wrought iron axles, and various other ingenious contrivances. Messrs. Kennan and Son, somewhat in the same line, also had a very excellent and varied collection, comprising double action log and tooth billet saws, felling and splitting axes, tools for knotting fence wire, straighteners, strainers, jointed ladders, foresters' tools, Green's patent lawn mowers, &c., &c. Messrs. J. B. Brown and Co., of Cannon-street, London, occupied a most important position at the show, and their display of goods was very excellent, comprising chiefly cast-iron gate pillars, carriage gates, ornamental portable fences, wickets, garden stools and chairs, Medici vases, and Shanks' (Arbroath) patent hand, and pony or donkey power mowing, rolling, collecting and delivering machines,—a useful and ingenious invention, which we hope to see extensively adopted. In the matter of ornamental and plain entrance gates, strained wire fencing, cast-iron pig troughs, &c., &c., the eminent firm of Thomas Perry and Son, Bilston and Glasgow, occupied, as on many previous occasions, a prominent position.

Messrs. Francis Morton and Co., of Liverpool, displayed a variety of fencing of considerable merit, such as we should be greatly pleased to see introduced extensively in Ireland, in preference to the rude appliances, or in fact to any that we know of hitherto in vogue. Their stand was specially visited and carefully inspected, as well by professionals as the general public. Messrs. E. Hernulewicz and Co. also exhibited manufactures of this character, together with other goods of some excellence. Among the engineers we noticed—Smith, Brothers, Glasgow; Clayton, Shuttleworth, and Co., Lincoln; R. and J. Rankin, Liverpool; Barrett, Exall, and Andrewes, of Reading; Fry, Bristol; Hornsby and Long, Grantham; Picksley, Sims, and Co., Leigh, &c., &c. We should specially admire an ingenious India rubber valve pump, by Perreaux and Company, exhibited at the stand of Messrs. Ferguson and Co., waterproof garment manufacturer, Grafton-street.

ANOTHER EXHIBITION MANIA.

THE year 1862 is destined to inaugurate another great era in the industrial advancement of the age. England, ever foremost in the van of progress, will lead as before, and doubtless her previous imitators—France, America, Scotland, and our own little island—will speedily follow in her wake. Dublin, we are disposed to think, will not be behind, nor will her effort suffer by comparison with other capitals of equivent commercial status. Another "William Dargan" *may* not come forward, but we trust that as the great work of that noble-hearted philanthropist, though leaving wholesome results, has partially become only a matter of memory and pleasing reflection, in this next instance, the combined exertions of our well-wishers to national progress will effect a substantial and permanent realization of the Sydenham or *(in embryo)* Muswell Hill people's palace type.

Time and distance are daily yielding to the conquering hand of science, and facilities of intercourse in 1862 being increased ten-fold before those of '51, we predict that as commercial speculations the coming "great exhibitions" will be crowned with success, and as a display of the resources of civilized nations, will shine resplendent.

We learn with gratification that at the exhibition of the Royal Hibernian Academy, which will be opened in a few days, a varied and rich treat will be presented to the lovers of the fine arts. Her Majesty has been pleased to lend a large historical painting; Belgian and Flemish artists have contributed several works of merit, and there are nearly *one hundred* pictures by English and Scotch painters, while our native artists supply more and better works than on *any* former occasion. Such reviving symptoms, though to a large extent attributable to the inducements offered by the two Art Unions whose prizes will be selected from the collection, are also greatly owing to the energy and earnestness of the present officers of this Institution, with whom, in an especial manner, the names of George F. Mulvany and B. Mulrenin, the worthy treasurer and secretary respectively, are associated.

IMPROVEMENT OF THE CITY.

EACH month we are gratified to chronicle some new particulars which testify to the rapid progress of our metropolis and its suburbs; and the building season has now set in with every apparent prospect of its being the busiest yet, despite the patent facts, that money is comparatively scarce, discount high, materials of all kinds and provisions—both for man and beast—unprecedentedly dear, workmen scarce, and wages proportionately greater in consequence; and the old hackneyed phrase of "bad times," is as present now in grumblers' mouths as ever—yet, strange inconsistency, we prosper! Our suburbs are extending, green fields are metamorphosed into populous districts, antiquated shop-fronts vanish beneath the hands of "ye modern architects," commercial palaces are raised instead, ecclesiastical and other edifices of uncommon beauty adorn our thoroughfares, "bustle" is the word in every quarter, and the welcome sounds of the hammer and trowel are met at each step. The most significant statistical evidence of the progress being made is to be found in the recently-issued report of the Collector-General of Rates, which, considering the facilities at command of that official, may be regarded as an unquestionable authority. We must, however, remind the worthy Collector that he is indebted to the DUBLIN BUILDER as the original source of information for many items in his report, which through some inadvertence seem not to be acknowledged; but we pass it over without further comment. We subjoin a few extracts:—

"*Arran-quay Ward.*—In many portions property is much improved; but in the old business streets—Church, Barrack, and Tighe-streets, &c. — property seems rather worse, but on the *whole* a slight improvement has taken place.

"*Inns-quay Ward*—The private portion is very much improved; but in consequence of the extension of the Four Courts, many of the old business houses have been taken possession of, and the adjoining property has been much injured, with a prospect, however, of *ultimate* improvement.

"*Mountjoy Ward.*—This district has, in many instances, much improved; many tenements hitherto untenanted are now occupied. Although, in the poorer localities, there is no apparent change, yet all parties appeared to have full employment.

"*North City Ward.*—There is a manifest improvement here —business increasing, and tenants for vacant premises much easier found, at higher rents.

"*North Dock Ward.*—The improvement in the condition of this ward still progresses. The number of unoccupied houses has decreased from 132 in 1858, to 94 at the close of the past year.

"*Rotundo Ward.*—Presents a less favourable appearance than in 1858.

"*Fitzwilliam Ward.*—Still continues to improve. Many new houses have been built during the year.

"*Mansion House Ward.*—The same observations apply to the private streets in this ward.

"*Merchants'-quay Ward.*—There is little improvement.

"*Royal Exchange Ward.*—Improvements in this ward are going on steadily. Several houses are being taken down and rebuilt, exhibiting shops of a greatly improved appearence.

"*South City Ward.*—The same remarks apply to this ward.

"*South Dock Ward.*—This ward is much improved. Several premises on Sir John's-quay and that neighbourhood, which were idle some years, are now occupied by timber-merchants, builders, &c., and the building trade is more prosperous at present than it has been for many years in Dublin.

"*Trinity Ward.*—This ward is also improved. The attractions of new buildings, such as the Kildare-street Club-house, also the Turkish Baths, in Lincoln-place, are remarkable.

"*Usher's-quay Ward.*—There is no material difference here.

"*Wood-quay Ward*—This ward is improving."

The General Inspector reports as follows:—"The wards continue to present an improving appearance; in some it may not be so perceptible as in others. In Inns-quay Ward a number of houses in Old Church-street, Anderson's-court, Morgan-place, and Pill-lane, are now in possession of the Board of Works, for the purpose of extending the law courts.[*] A considerable addition will be made to the appearance of the city. Talbot-street, near the Drogheda Railway, has been much improved by the fronting of the hotel, and some new buildings. It is in contemplation to widen a portion of this street.[†] In the North Dock Ward some very desirable improvements are observable. In Beaver-street (a very poor locality) houses which have been in ruins for many years are now replaced by new ones, and a large dairy-yard; and the old vinegar works (ruins), in Sheriff-street, east, have been taken down, and four houses built on the site. More dwellings have been raised of late years in Church-road[‡] and the vicinity of Amiens-street than could have been anticipated from the nature of the site, it being, not long since, considered an irreclaimable swamp. An English proprietor is about building several cottages in this locality.[§] There is at present a row of houses building in a part of New-street. In Grafton-street, many of the old houses are giving way to modern structures, including another monster house, now near completion. Great Brunswick-street continues to improve. Another large plot of ground, similar to that alluded to in my last report, has been taken as a timber-yard, and at present workshops and other buildings are in course of erection on it. I have not observed this year that cleanliness so remarkable last year, and so essential to the public health. In the narrow lanes, courts, and alleys there is a visible indication of neglect. The soil is swept in heaps, and so left for future removal; whereas last year there were handcarts to carry it off at once. Three of the principal monster houses are, and have been, making additions and improvements to their premises. A gentleman connected with a heavy branch of the building trade (the marble business) has, within the last year, extended his workshops considerably, and erected a steam apparatus, the first employed in his line in this city."[‖]

It is calculated, amongst those best able to form a judgment, that the increase in value, in five years, has been 20 to 30 per cent. A tenant in Mountjoy-square, who paid £600 to be relieved from the responsibility of his lease, felt it an advantage to be allowed to remain in possession from year to year at his old rent of £110. A house in Rutland-square, the interest of which was purchased in the Encumbered Estates Court for £400, has been sold for £1,100. Fines are beginning again to be freely paid. Houses are disposed of, at the south side, for £100 and £110 a-year, with fines of £300 and £400, for which less than the present rent would have been gladly accepted a little time back, without any fine at all. Furnished houses have had a large increase in value: one of them, in Merrion-square, was lately set for six months, at a rent of 350 guineas!

Our current number comprises—as also shall our subsequent—many items valuable for introduction into the Collector's *next* report, and we only ask, as a matter of justice, that when information is obtained through us, it may be so acknowledged.

NEW FINE ART GALLERY IN NEW YORK.

H. W. Derby, Esq., of the Dusseldorf Gallery, has purchased a lot on Broadway, between Houston and Bleecker-streets, opposite Laura Keene's Theatre, on which he intends erecting a fine art gallery. It will be 34 feet front by 200 feet deep, running through to Mercer-street. It will be built in the Italian style, five storeys high, with marble front. The second storey arches will rest upon three Caryatides, or female figures, larger than life, and representing Architecture, Painting, and Sculpture. The gallery will be divided into separate apartments of sculpture, paintings by native artists, and specimens of foreign art. The interior will be heated upon approved principles, and furnished with waiting-rooms elegantly fitted up for the convenience of ladies. The first floor will contain one of the most capacious stores on Broadway, with basement and sub-cellar running through the entire length of the building. The gallery will be on the second floor—150 feet of it being lit by sky-lights—with 50 feet of the front portion of the building occupied as offices. The introduction of sculpture to the front of the building will be one of its chief characteristics, and, if we mistake not, will form a pleasing feature, and stand out in bold relief, among the architectural monstrosities and beauties which adorn the long line of our great thoroughfare. The architect is Mr. J. R. Hamilton.—*New York Architects' and Mechanics' Journal.*

[‖] Mr. Alexander Ballantine, of Upper Dorset-street, is the person alluded to.

PROGRESS OF DERRY.[*]

City Improvements.—The streets and roadways have been considerably improved. The first local Improvement Act was passed in August, 1848, and a sum of £40,000 expended in flagging, paving, and widening the streets, erecting new water-works, and carrying out a general system of street and house sewage. In addition to those works, a new cemetery has been opened by the corporation, commanding a magnificent prospect of the Headlands of Inishowen, and the bluff basalt and limestone peaks of Magilligan and Benevenue. On an opposite eminence stands the city, visible on the west and south, crowned on the apex of the hill by the old Cathedral Church. There are 28 acres in the cemetery, 14 being already employed for sepulture. Under the second local Improvement Act, of June, 1855, an additional sum of £10,000 was expended in city improvements. Londonderry is well provided with extensive and commodious markets for every kind of produce, and has a powder magazine in a detached building about a statute mile from the city.

The Magee College stands on a commanding eminence on the west side of the Foyle, and a short distance from the city. The style is mixed Gothic and Tudor. It is 190 feet long by 58; and the front elevation to the top of the vane on the centre octagonal tower is 101 feet; height of front elevation of north and south wings to the finale of the turrets, 58. A central tower springs from the face of the hall above the main doorway, and is supported by groined arches of the most tasteful design and workmanship. The base of tower consists of an elaborately traced two-tier bay window, finished at top with ornamental finials. The octagonal tower consists of three steps or bays, each square of which has sunk and chamfered panels, with cusped heads and trefoils. The water-tables at the top are terminated with finials. From the embattlement of the main tower the remaining portion of the turret consists of a spire, resting on eight small turrets, with gurgoyles, finished with a vane, 7 ft. 8 in. high. A corbelled window is carried up from the face of the wall in the north wing, which is 38 ft. 9 in. high, by 12 ft. 11 in broad. The windows have label mouldings, and nondescript heads and gurgoyles. The cornice tracing, with nondescript ornaments, is carried round the entire front façade to the tower. In the front of the south wing is a two-tier bay window, 20 ft. 8 in., by 11 ft. 2 in. wide, which light the library. In the front elevation of the north, as in the south wing, are two tiers of windows, divided by mullions into three lights, six of which, with a corresponding number in the rear of the south wing, light the examination hall. In the south gable is a window, 12 ft. 8 in. in width, by 20 ft. 4 in. high, topped by a wheel window of neat design. On entering by the main door, there is first a spacious arched hall running across the building, and 16 ft. wide. Off the hall, in the south wing, there are the porter's room, vestibule, and robing room. From the vestibule, entrance is had to the examination hall, 72 feet, by 38 ft. 8 in. wide at the transept; height to ridge, 49 ft. 6 in.; and 33 ft. 5 in. to eaves. The roof is open, with principals supported on stone corbels, wrought, stained, varnished, and sheeted between rafters. Off the transept, and to the front, is the library, which is in two stories, reached by a neat circular staircase. From the grand hall, the apartments on the ground floor of the north wing are, the council and visitor's room, 21 ft. 3 in. by 12 ft. 2 in., whence there is an entrance to a corridor; and from the corridor there are entrances to a class-room for 100, 32 ft. 6 in. by 30 ft.; and to a student's room, 12 ft. 11 in. wide, by 38 ft. 0 in. long; and a class-room for 75 students, 18 ft. 10 in. by 29 ft. Off the corridor to the rear are the water-closets and back entrance. There is also a front entrance for students in the north wing. The grand staircase springs from the entrance hall, and leads up to the museum, which is divided into three apartments, lighted principally by the bay window in the centre tower. The space occupied by the museum will be 25 ft. 10 in. by 40 ft. Beyond museum, and in the north wing, is a corridor leading to a class-room for 50, 21 ft. 3 in. by 18 ft 6 in.; a class-room for 150, 48 ft. 9 in. by 29 ft. 3 in., lighted by corbelled window already noticed. To the rere are the laboratory, closets, &c. The front and ends, together with the wall of the tower, are built of Scotch sandstone, and in coursed ashlar; the rere is built in random ashlar of stone from a neighbouring quarry. The ridge is composed of ornamental ridge tile. The roof over the tower and north wing is truncated and finished round the ridge with spires and esplanading. The design is by Mr. E. P. Gribbon, Architect, Dublin; resident architect, Mr Stewart Gordon, County Surveyor; Clerk of Works, Mr. Arthur Kent; Contractor, Mr. Matthew M'Clelland. The cost of the building alone is about £8.000.

District National Model School.—Is built on an eminence, parallel with the County Infirmary, and overlooks the Foyle and northern portions of the city. It is in the Tudor style, and presents a front façade of three pointed antique gables, and two bays, perforated by several large windows of faultless proportion and elegance of design, finished with Gothic arched tops. A semi-Gothic window surmounts the bay window in the centre of the block. Entrance is had in the front of the building by a spacious hall into a corridor, which runs from the south wing to the entrance of the north wing. In the basement storey of the south wing there are the kitchen, larder, servants' room, scullery, and fuel store. On ground floor of south wing (which is the only part of the building having a basement storey and attic) are the pupil teachers' room, the book room, and the masters' sitting room. In the attic are dormitories for the master and pupil teachers, divided into eight apartments. Off the corridor already mentioned are, on the south side, two offices. There is a lavatory, &c., above these rooms. In the front of the main building is the maritime school, 18 feet square; the drawing school, 25 ft. by 18 ft.; museum and library, 21 ft. by 18 ft.; and the infant school, 48 ft. by 25 ft. At the rere of the main building, off the corridor, is the boys' school, 40 ft. by 50 ft., which will have an open roof, supported on a row of columns, 15 ft. high. To the right of this spacious apartment are the porch, and cap and cloak room for boys; the boys' class room, infants' class room, and girls' class room, with porch and cloak room for girls and infants, to the right. In the north wing is the girls' school-room, 48 ft. by 25 ft., with open roof, principals supported on antique corbels, as is the case in the other schools. From the boys' school there is an entrance by a handsome Gothic porch to the play-ground in the rere, which is divided by a wall from the play-ground of the girls and infants. The walls will have projecting coping to protect the children in wet weather. The ground plan shows a total length of 208 feet; width irregular. The schools will have open roofs, and are well ventilated. It was erected by the Board of Public Works, Mr. James Owen, Architect; clerk of works, Mr. Arthur Kent; contractors, Messrs. Boyd, of Derry There will be a circular double entrance of chaste Gothic design, fronting the Asylum Road, which will form a beautiful terminus to the new street to be erected on that thoroughfare. The estimated cost of all the works, when completed, will be near £6,000. This includes lawn, garden, &c., which cover about three acres.

The New Iron Bridge, Derry.—The contract for the iron-chambered bridge, now in course of erection across the Foyle, was entered into by Messrs Joseph Butler, & Co., Stanningley, near Leeds, in the summer of 1859, for the sum of £59,000, contingent on the piers being sunk to a depth of 60 feet, and £64,500 if sunk 80 feet below the bed of the river. Mr. Charles Pagett, practical machinist and engineer, directs the work. Four metal cylinders have been partially sunk. The first two, forming one pier, are near their permanent destination of 32 feet below the bed of the river; and the second two cylinders have been sunk 27 feet, but these have still to be driven a considerable depth. The cylinders are of cast metal, 11 feet in diameter, and at extreme width stand 35 feet apart. The span from pier to pier is 119 feet in the clear; and there will be eight piers, or sixteen cylindrical columns, independent of the massive pier of 30 feet in diameter, on which is to be placed the swivel bridge or turn-table, which will give an opening in the platform of 45 feet for the upward navigation of the river. The works are in a forward state for commencing the sinking of the third row of cylinders. When these piers shall have been permanently fixed on the solid foundation, which in many cases will be 100 feet to the rock, their cavities will be filled with concrete. Stretching from pier to pier, longitudinal girders of great thickness will span the intervening space, and these, with cross girders, will support a floor of solid timber, 6 inches thick, on which the permanent way for the railway will be laid. Springing from this platform, at intervals of 3 feet, are wrought iron crossbars, 8 inches double by 2 inches, with perpendicular girders fastened at the centre by 2½ in. steel pins, and at the lower and upper platforms with 5 in. steel pins. This forms a trellis-work on either side of the bridge, within which the railway trafic will pass. The piers are to be continued to the top of the trellis-work of the lower chamber; and the castings will show a semi-octagon pier, with trellis ornaments. From the flooring of the upper chamber, or ordinary traffic bridge, the piers will be continued, forming pillars, terminated by gas lamps. The floor of the upper chamber or bridge will be laid, as in the case of the lower chamber, on longitudinal and transverse girders. It will consist of iron plate flooring, covered with asphalte, and paved with oak timber. The handrail and trellis-work will protect pedestrians at each side, and taken in conjunction with the cornices and pillar lamps, terminating the massive metal cylinders on which the whole structure rests, will be ornamental in a high degree. The foregoing work is embraced in the contract of Messrs. Butler & Co., but the stone approaches at either side are not yet contracted for.

The new line of Quays, Graving Docks, &c.—In the memory of many still living the only thing presenting the appearance of a quay was a mud-bank called the Ship-quay, and the venerable "Wooden Wharf." Subsequently a number of docks and piers, with sea-fronts were constructed, and these joined to private wharves, were the sole accommodation for the shipping. The new line of quays were commenced in August, 1856, by Mr. M'Cormick, the contractor, under the direction of Messrs. D. and J. Stephenson, Edinburgh; resident engineer, Mr. D. Macdonald. At the present time there is completed a line of quayage of 2,817 feet, on the west side of the river; and there is contracted for, and in course of construction, double that length of quayage, in continuation, to the new Graving Dock. New approaches have been made to the quays, and there is not in Ireland at present a more commodious harbour. At the Waterside, a sea wall 1,300 feet is all but completed. The Harbour Commissioners have spent £25,000 on the improvements.

---

[*] We are indebted for the heads of these particulars to the excellent Almanac published by our contemporary, the *Derry Standard*.

The Graving Dock, contracted for by Mr. Hugh Kinghorn, Leith, is a gigantic work for the Harbour Commissioners to undertake concurrently with the quay extension, but they are successfully carrying it out. The original contract was £17,701 7s. 3d.; but the dock has since been lengthened fifty feet, and the gross cost will not be under £20,000. It must be completed in 1860. The dock is 365 feet long, 50 feet in width at base, and 86 at feet top. There will be 18 feet water over the sluice at the gate at flood tide. To the dock there is an approach from the breast of the quay wall of 70 feet, and at the quay breast there will be 18 feet water at low tide. The work is of solid masonry, huge stone blocks being used in its construction. A part of Mr. Kinghorn's contract is the formation of 300 feet of sea wall and wharfage to the north of the Graving Dock, and 100 feet to the south, which will join the other contract. When completed, the quays on the city side will extend from the Enniskillen Railway Terminus to Pennyburn, near the Buncrana-road.

River Improvements.—Arrangements are being made for dredging the Flats, and cutting through Cutmore Point. A powerful dredging machine is being constructed for these purposes. The dredge will be kept at the Flats during the summer months till the work is completed, and in the winter months it will be used deepening the river opposite the quays, so as to increase the draught of water. The Commissioners are also empowered by their act to straighten the channel in Ross's Bay, and to clear away the sand banks which cause the navigation of the river to be a little tortuous at that point. This, we believe, will be the last extensive work executed by the Port and Harbour Board. The cost of deepening the Flats, &c., will be about £30,000. Mr. Macdonald, resident engineer.

A LETTER FROM LONDON.

The Conduit-street new rooms—Professor Donaldson on "the arrangement of a Roman consular house," &c., "and the scrubbing and currycombing of the Turkish bath"—the Duke's and Nelson's monuments—light and delight—a model.

London, April, 1860.

At home, and having dined "unscathed," it might have been pardonable to let well alone and remain there; but Shakspeare, I think, has rightly said, "the love of labour physics pain,"[*] and the service of my beloved architecture is ever a pleasure, so I was soon on my way to the new rooms in Conduit-street, soliloquising Cato:—

> "'Tis not in mortals to command success;
> But we'll do more, Sempronius, we'll deserve it."[†]

Now what is called the *movement* in architecture seemed at first to be of a retrogade tendency, at the rate of two steps backward for one forward, and, as the *Examiner* said of the volunteers the other day, "how to get into the right groove after a start in the wrong one is the difficulty;" but the difficulty will, no doubt, be fairly overcome and the interests of art subserved.

There are among *architects* in every city those who like to speak upon *every* subject and to talk upon *every* occasion, even in your own dear Dublin, where I am reminded of *one* especially, and must exclaim of him, that

> "He *will* talk—ye gods, how he *will* talk."

while the grave endurance of the hearers affords a *rich* exemplification of the line—

> "How *poor* are they that have not patience."

Professor Donaldson is a frequent speaker, but his remarks are usually pertinent to the subject, and so rendered as to leave one indebted to him. They could rarely be better given by another. The treat which drew me out was a lecture by him on a most interesting subject, "The arrangement of a Roman consular house, and the every-day life of a Roman patrician," at the Architectural Exhibition—one of the forward steps of the movement just mentioned, and which appears to be an institution in its own right. It is a good feature of the London lectures that they commence punctually at the time prescribed, and, being a few minutes after it, the business was "on" at the time of my arrival last night. The scene was most elegant.

The access to the room is a descent of a few broad steps, and I noticed one or two of the designs from the late competition for the Duke of Wellington's monument in St. Paul's, which makes me pause just to say that none of them are to be executed. Perhaps you may recollect that when Nelson's monument was to be competed for, architects as well as sculptors, in fact anyone, might submit designs, and an architect succeeded. But in the Duke's case patronage was laid open to sculptors only; but now, when all this has been done, and premiums awarded, the services of an architect are quietly called in! The Duke would not have thus read the motto, *Palmam qui meruit ferat*.

But to return to my subject. At the foot of the steps is the entrance to an ante-room, through which you pass into the principal gallery. This apartment is of an oblong form, lighted from the top, according to the mode suggested by the Glyptotheck at Munich, and since followed in many instances with great success, of which one example at the Brompton Museum has impressed me very strongly. The roof or ceiling in Conduit-street is semicircular, and the central portion is of glass, so that no shadow is cast upon the walls and pictures. At night, rings of gas jets under the skylights produce the same effect, and pictures, like other beauties, are seldom injured by the change. The floor was subdued by some greenish carpet, where passing room to the chairs occupied by the closely packed audience revealed its existence, and so took nothing from the walls, but allowed the eye to range uninterruptedly over the specimens of art arranged upon them. Besides the works proper to the Exhibition, there were the illustrations pertaining to the lecture. A plan of a Roman house, with its courts, enclosed gardens, and surrounding shops—for the ancient nobles were not indifferent to the revenues thus obtainable—and, besides those which were let to tenants, some were filled with the produce of the owner's farms, the wine, oil, and other produce of which might be had, as we should say, direct from the grower. A section of the house, showing the colonnades, courts, and upper arrangements, with the apartments for ladies, who, although maintaining a certain familiar intercourse with each other, lived in comparative seclusion—no parallel to the *soirée* and ball of modern times being then known. Hospitality expended itself in banquets, followed by performances, in which the family and guests were only spectators, and consisting of music, dancing, wrestling, gladiatorial combats. I can, however, only further mention the plan of some baths, in which the professor recounted with admirable pleasantness the sudorific stages of a Turkish bath, in which he was so rubbed and scrubbed, shampooed and currycombed, that the wonder was he should have survived to delight his hearers with so instructive and entertaining a discourse, and to afford so gratifying an example of the modern patrician.

OBITUARY.

We have to announce the demise, at a very advanced age, of the head of the respectable firm of Messrs. Beardwood and Sons, builders, in this city. The deceased executed several important works—amongst others, the extensive alterations and additions at Maynooth College, and was highly respected for his integrity. The remains were attended to the grave by a number of both architects, builders, and tradesmen, besides friends and relatives, and the funeral was one of the largest ever seen in this city.

LAW NOTE.

Bolton v. *Tyrrell, and Tyrrell* v. *Bolton.*—These two actions were referred to the arbitration and award of Mr. W. Murray and Mr. E. P. Gribbon, architects, with power to choose an umpire. The matters in dispute consisted respectively of amounts claimed for work and labour by Mr. S. H. Bolton, a builder, and a cross action for delay and consequent damages—referred to arbitration from the Court of Queen's Bench. The award on both issues was in favour of the builder.

WAR DEPARTMENT.

Mr. Michael Walsh, of Foynes, is declared the contractor for the works at the Shannon Forts, on the Carrig and Scattery Islands.

Tenders are about being taken in for a chapel school in Newbridge Barrack.

---

[*] Query for Shaksperian commentators: "The labour we delight in physics pain."

[†] "The less I deserve the more merit in your bounty."—Shakspeare.

SCULPTURAL ART.

"ARCHITECTURE" and her twin sister "Sculpture" advance by steady paces in our ecclesiastical edifices, and in addition to the particulars of various works in the latter department already chronicled in this journal, we feel pleasure in drawing special attention to the carving works at present in progress at Messrs. Hardman and Co.'s Dublin establishment. The grand high altar for Tipperary Roman Catholic Church is a noble work of art, and designed by the artists themselves. The width of the reredos is 27 feet, and the height nearly 30 feet; the groupings are beautiful, and represent respectively the sacrifices of Abel, Melchisedec, Noah, Abraham, Elias, and Solomon, each panel being 6 feet high by 3 feet 4 inches wide, surmounted by very rich canopies, supported on polished marble shafts of reddish colour. A figure of our blessed Lord, 6 feet high, in the act of benediction, and placed under a tall canopy, very richly crocketed and pinnacled, and supported by Purbeck green marble shafts, occupies the centre, with on the left a life-size figure of St. Michael the archangel, under a similar canopy, and on the right, St. Patrick, life-size—the squares between the canopies being filled in with the groupings above enumerated. This altar, we are informed, will, when completed, be the largest and most elaborate erected in the United Kingdom since the Reformation. The same firm are also executing a quantity of carvings for various churches in England and Scotland. The *employees* are mostly natives of Ireland, the juniors undergoing a systematic course of training in their respective departments, which, if adopted in kindred establishments, would materially enhance the artistic excellence of the rising generation.

ART UNION OF IRELAND.

THE day for closing the subscription lists to this national institution being near at hand, we would suggest to those who are not members already, to become such without delay. The first drawing of prizes was conducted in the most *bona fide* manner, to the perfect satisfaction of the members and the public, and, we with much pleasure also add, to the pecuniary benefit of the undertaking; but strengthened now by an immensely increased number of supporters, the inducements offered by the *second* drawing, which will take place on the 6th inst., are twofold The country lists virtually closed on the 30th ult., but members will be enrolled in the metropolis until the 3rd inst.

NORMAL AND MODEL SCHOOL BUILDING AT TORONTO, CANADA WEST.

THE schools are situated in the centre of an open square seven acres and a-half in extent, considerably elevated above the business parts of the city, and overlooking the bay from which they are distant about three-fourths of a mile. The legislative grant for the purchase of the site and the erection of the building was £15,000. The principal school has a frontage of 184 feet 4 inches, and depth on flanks of 85 feet 4 inches. The front is of the Roman Doric order of Palladian character, with central projection displaying four pilasters carried up two storys, and having a metoped and triglyphed entablature above, surmounted by a pediment, and with an open Doric cupola—to whose summit the height is 95 feet—forming a crowning feature. As a guide to the dimensions of the several apartments shown on the accompanying plan, we may state that the scale is 32 feet to an inch. The following are explanations of reference letters :—

A—Male and female student's staircases respectively.

B—Position of gallery above central hall.

C D—Entrances for male and female students.

In the theatre, which is designed to accommodate 470 persons, exclusive of the galleries, and including them 620, A B C denote the aisles and seats, the lecturer's platform being placed between B and C ; D D are the respective entrances to this apartment.

The semicircular corridor communicates with the model school and education offices (not shown in the cut) which have a frontage of 175 feet 6 inches by 59 feet 6 inches in depth, and comprise two large school rooms, one for each sex, 56 feet 6 inches by 33 feet, and capable of accommodating 300 children, together with 4 class rooms adjoining them about 17 feet by 15 feet 6 inches each, together with minor apartments.

On the first floor of the normal buildings are the museum—placed in central projection and communicating with the gallery over hall—two class rooms 56 feet by 36 feet at right and left of the latter, two others in each wing, a library, laboratory, master's rooms, &c. There are also in the basement story the residence of the janitor together with furnace rooms, &c., &c.

SANITARY SCIENCE IN GALWAY.

REFERRING to the sanitary condition of "the citie of the tribes," the local *Express* has the following able remarks, which in our devotion to the cause generally, and in good feeling for the well-being of that improving town—destined to fulfill a great mission of universal import—especially, we feel much pleasure in partly reprinting :—

We are all familiar with the formula that "Cleanliness is next to Godliness," and yet it is surprising how little we do to insist upon its general obligation. We are most of us satisfied if our Town Commissioners or Boards of Health take measures for the cleansing of our more public streets, but are generally indifferent as to the condition of the slums and passages of our large towns. Yet it is often in these reeking and overcrowded alleys that contagious disease originates, and thence spreads among the community. We have provided medical advice and assistance for those who are themselves unable to pay for it, and resting satisfied with curative expedients, we fail to take the precautions, which, if adopted in time, will render disease to a large degree impossible. No doubt people are jealous of any interference with their domestic arrangements, and we admit there are insuperable difficulties in the way of a public inspection of private houses. At the same time, every man should know that he has no right to keep his house in a condition that is dangerous to the health of his neighbourhood. If he be not careful in this respect, his house will become a public nuisance, and the law will interpose for the protection of the public. However, even in cases which the law cannot reach, it behoves every one of us to be active in the public behalf. To landlords and clergymen we would especially appeal. The former class can effectually enforce such sanitary regulations as are necessary, and we believe that watchfulness and remonstrance from the clergy of all denominations will prove most beneficial. They can advise not only as to the necessity of cleanliness, but also of those other principles of regimen, temperance and habit, which promote what may be called physical morality. Pure air, pure water, and temperance in eating and drinking, are the great hygienic rules, and their value cannot be too frequently enforced.

We have no wish, indeed we have no reason, to complain of the efficiency of our Town Commissioners, in respect to the cleansing of our streets. Under the guidance of their Reverend Chairman, we have of late observed a most laudable zeal in this direction, and it gives us much pleasure to say that their exertions have not been in vain. We have noticed a great improvement in the streets of Galway, and we believe that, at present, they are in as creditable a condition as in any considerable town in the country. As soon, however, as we leave the public thoroughfares, we find a condition of things far from satisfactory. There can be no doubt that various forms of disease are caused by the generation of poisons from decaying vegetable and animal matter. We regret to say that more than one of these diseases is now prevalent in Galway. Small-pox and measles are raging with more than usual virulence, and though they are to be found effecting all classes of society, it is to be feared that they chiefly prevail in those quarters where the producing causes abundantly exist. Happily, however, those putrid poisons which are so active in the production of disease, are, to a greater or less degree, subject to human control, and that control may be exercised more or less by every one of us. We cannot wonder that disease should be constant in the neighbourhood of a stagnant cesspool, and in the absence of everything like drainage. Introduce, however, a proper system of drainage, and the cause of complaint will no longer exist.

We are most anxious that some steps should be taken to improve the drainage and water supply of this town. Though there is abundance of water about the town, it is most inaccessible for domestic purposes—and what is even worse, it is, from the want of proper filtration, most unwholesome and disagreeable. We urgently press upon the inhabitants of this town the necessity of being active in this matter, and in the no less important matter of drainage. Even in an economic point of view they are important.

We are requested to state that Mr. Raffles Brown, Architect, was not one of the memorable quartette—*Brown, Jones, Smith*, and *Robinson*—alluded to at page 211, in the Rathgar Presbyterian Church affair.

The bricklayers of New York are on a strike. They gave notice that from and after the 2nd day of April they would demand two dollars per day, instead of one dollar and seventy-five cents, which are the present wages.

SYDNEY HOUSES OF PARLIAMENT COMPETITION.—The contour plan and general conditions may be inspected at the office of this journal.

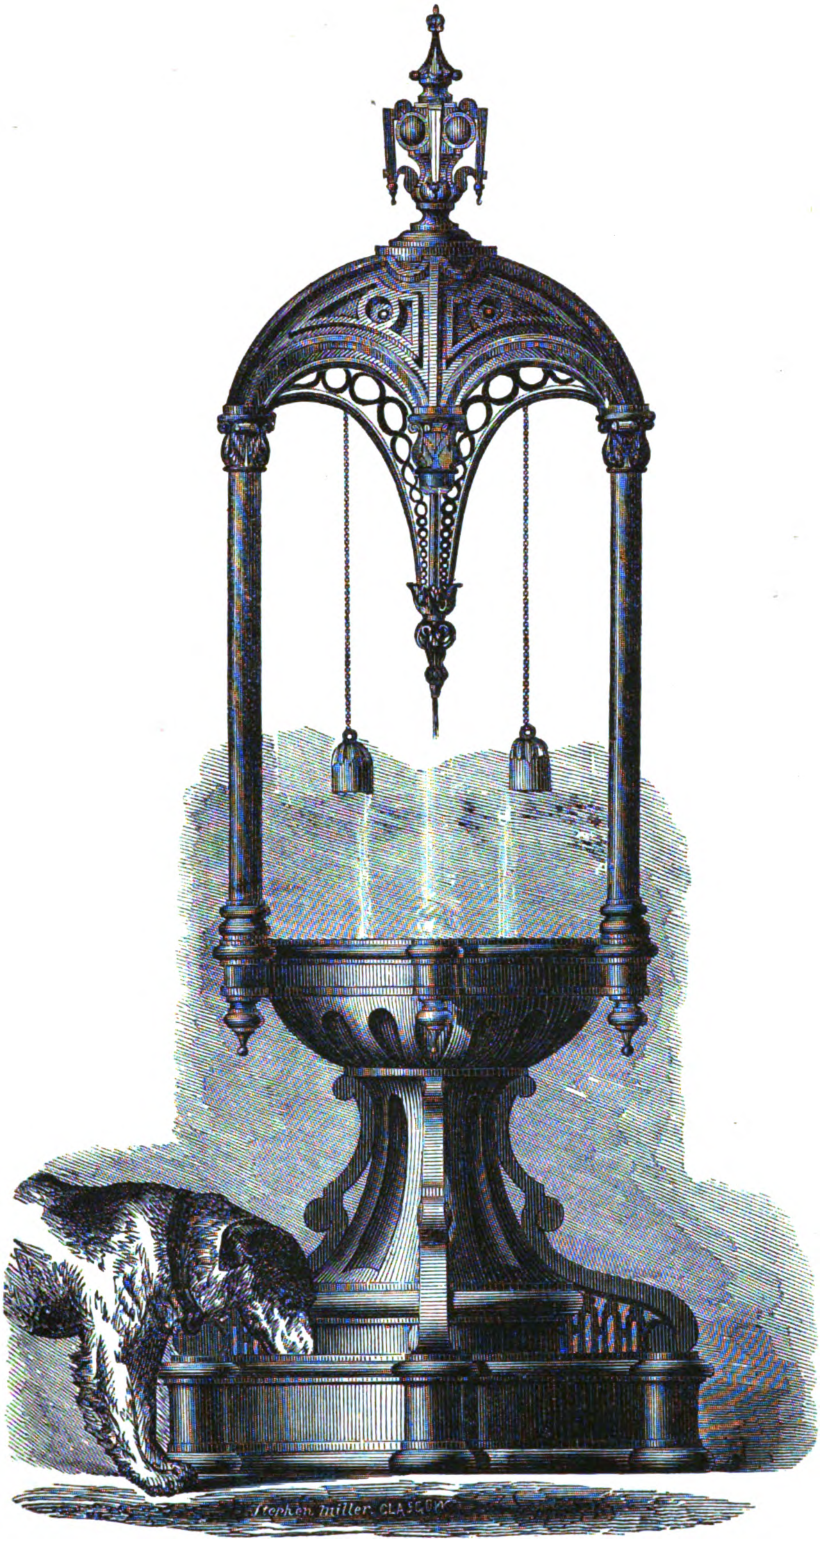
For Description see page 252.



DESIGN FOR A CANOPIED DRINKING FOUNTAIN.

DESIGN FOR A CANOPIED FOUNTAIN.

THIS fountain affords facility of access from all sides, and its architectural merits are greatly enhanced by the introduction of a light canopy, with panelled spandrils and soffet. A constant stream of water is obtainable through a single jet, communicating with a tube placed centrally under the canopy, whence the liquid descends vertically into the basin below, and thence through the supporting pedestal to the dog-trough at base: or a self-closing tap may be introduced, by which a modified supply may be regulated. The drinking cups are suspended from chains of sufficient length at either side of the jet, and being inverted, their thorough draining is secured. The total height, as represented in this drawing, is 6 feet, and the diameter 2 feet 6 inches. This design provides for cast iron construction, and is registered by Messrs. George Smith and Co., of Sun Foundry, Glasgow.

Engineering Journal.

ARDGLASS HARBOUR.

That we have not yet attained to a knowledge of the best mode of constructing breakwaters of stone and sea walls, is fully proved, by their failure in many places, and by the diversity of opinion which exists amongst engineers on the subject of their construction. The most important matter to be considered in their formation is the batter, or degree of slope, which should be given to the face of the structure presented to the action of the waves. On this point there is no uniformity of opinion. Every angle of slope has had its advocates, from the smallest to the perpendicular. The majority, however, consider that the nearer the slope of the breakwater approaches to the horizontal, the better will it be able to resist the action and shock of the waves. The Eddystone lighthouse proves this opinion untenable. One of the most complete failures that has taken place has been that of the pier and breakwater constructed at Ardglass, on the east coast of the County Down, about thirty years since. The breakwater and pier had been finished, and the contractor for the lighthouse on the circular pier-head had the work taken off his hands, when a storm arose and made a very small breach in the neck of the pier. Information of this was forwarded to the Board of Public Works, under whose care the harbour then was, as a considerable grant had very properly been made by Government, through, we suppose, the Board of Works, for the erection of the harbour. The Board, either conceiving that the matter was not pressing, or delayed in their action by what is usually termed routine, or red-tapeism, took no action in the matter for some time after the fact of the breach in the pier having been communicated to their secretary. In the meantime another storm arose from the south-east—the most dangerous of all for the safety of the harbour—and before it ceased the waves swept the whole structure with the besom of destruction. Down to low water mark not a stone of the strueture remained in its proper place; the whole, lighthouse and all, were swept into the harbour.

The works at this place had been designed by the late Sir John Rennie, and executed under his assistants. The late William Ogilvie, Esq , the owner of the town, had contributed liberally towards the payment, and, as we have already said, the government of the day gave a grant of, we believe, £15,000.

The work under water was constructed with great care, by means of a diving-bell, with stones brought from the Isle of Man, squared and dressed, and strengthened with bar iron and upright bolts. We have seen a model of the pier on which the progression of the work was marked, and we consider its fault to have been want of sufficient magnitude to resist the impetus of the waves.

The greatest defect, however, lay in the construction of the breakwater, situated inland of the new pier, and intended to protect the older part of the works. This part of the works was formed with a coarse, slaty rock (clay slate) quarried in the immediate neighbourhood of the harbour, totally unfit for the purpose, as however large the block of stone might be at first, exposure to the action of the elements soon disintegrated them into multitudes of pieces; with these the slope of the breakwater was paved.

On referring to a copy of the specification for executing the works, we find that 260 feet was added to the length of the old pier, forming an angle of 150 degs. with it, being inclined at its extremity 25 feet further seaward than a straight line.

"The external face to batter from top of parapet (10 feet high) 2 horizontal to 1 perpendicular until it reaches the level of high water spring tides, from thence downwards to the level of low water of spring tides to batter 3 feet horizontal to 1 perpendicular; and then to have a bending or foreshore of 15 feet inside, and from the outer edge of this to the bottom of the sea to have a slope of 2 feet horizontal to 1 perpendicular, or more if requisite where the different inclinations of the respective slopes unite, this part to be greatly curved, in order to prevent any abrupt transition from one slope to another. The exterior slope down to low water to be faced with the best selected rubble laid upon its edge, in regular courses as near as may be inclining at the slope of 4 to 1 in the horizontal direction, and at right angles to the face in the vertical direction, and breaking bond well over each other. The heaviest stone should be placed at the commencement of the foreshore and middle of the slope, and the foreshore itself is to be rough set on edge, the stone extending from 2 to 3 feet below low water, or more, as they may turn out from the quarries."

So ran the specification, and we have no doubt but that the works were constructed in strict accordance therewith. The questions then arise, to whom shall we attach the blame that ne profitable result had been derived from the expenditure? and what were the defects in the construction of the harbour? The answer to the first question is self evident: eminent as Sir John Rennie was unquestionably as a harbour engineer, we find it impossible in this case to deny that for the failure of the structure *he* alone is responsible. In answer to the second question, two principal defects are evident in the design of the work—want of sufficient magnitude in the pier, and the mode of forming the exterior slope. Its inclination was four hose to one vertical. This seems to us a very great error in construction. When tho inclination is less than the angle of repose, the stones in the lower part are not pressed down by those above them, and consequently are easily detached from the mass by the incessant action of the waves; and as all those stones (clay slate) were broad and thin, foliated in their texture, and set on edge like a flat arch, with no retaining power save their own weight and the horizontal pressure of close setting, it is evident that one stone removed and the key, as it were, is taken from the arch, and the ruin of the whole quickly follows. The stone found in the neighbourhood owing to its slaty texture and liability to disentegration from the action of the elements, renders it totally unfit for sea works. It is a mistake also to suppose that a smooth surface will most effectually resist the shock of a wave. The pier at Kingstown Harbour, of which Sir John Rennie was also engineer, would have been long since washed down, as well as that of Ardglass, if its exterior slope had not been protected by throwing along the toe a breakwater of large blocks of granite, dropped in at random (*pierre perdue*) against which the waves spend their force and tear themselves to pieces in vain. Another error in the design of the harbour was in placing the extension of the pier exactly at right angles to the direction of the wind most dangerous to its safety. Placed in this direction the magnitude of the mass or the breadth of pier was required to be greater than in any other. If the direction of the new pier had been more to seaward, the most dangerous waves would then have struck the pier at an acute angle with diminished force, and changing their direction run inland and spent themselves on the rocks seaward of the old harbour. Without entering further on the subject at present, we are of opinion that the government should grant a few thousands, out of the seventy millions or so which they are yearly spending, to place the harbour of Ardglass in such a state that it would afford shelter to coasters, and accommodation to fishing boats which have assembled there to the number of 500 from England and various places on the Irish coast in former days, and might again, if shelter were provided for them.

The Cork and Youghal Railway.—The works have so far progressed between Killeagh and Youghal that the portion of the line from Dunkathal to Youghal will be opened for traffic immediately, if not before now.

Proposed Line of Railway from Castlewellan to Banbridge.—We understand that the survey of this projected line is completed. Four surveyors have been busily engaged on it for some time past, and the greater part of the money for its construction has been already subscribed.

Letterkenny Railway.—The estimate for this line of 15 miles is 100,000, or £6,500 a mile. There are no special engineering difficulties to contend with. A portion of the country through which the line was to pass was mountainous and rugged, but Mr. Bower, the engineer who has laid out the line, has successfully overcome these difficulties, by deviating from the direct course, and making easy gradients and curves.

We believe the first rails of the Metropolitan Railway will be publicly laid in June, and that all the shareholders will be invited to witness the ceremony.

Mr. John Cunningham, of Dalkey, is the contractor for the construction of the viaduct and other works on the Mallow and Fermoy Railway.

THE ARCHITECTURAL EXHIBITION, LONDON.

We were somewhat disappointed at the display this year, especially in the architectural department, which did not by any means stand the test of comparison with previous collections that we had the pleasure of inspecting, and as a whole was not highly creditable to a metropolis wherein a large proportion of the talent of the age—designers and draughtsmen—is centred. Yet there were a few admirable and beautifully-finished designs and subjects for study, especially those sent in competition for "the gold medal," for the Manchester assize courts, and those by our countryman (Mr. J. P. Jones) for the new Guildhall, Cambridge. Mr. Goldie, amongst other drawings, exhibited a design, in a geometric decorated style, for Ballymont Church, Co. Mayo, and Mr. Pugin for that of SS. Peter and Paul, at Cork. Would that the professionals practising in this country would take pattern by some of their English brethren, and infuse more originality and boldness of outline and details into their designs, as was the case with even the indifferent works at this exhibition!

In the building materials, inventions, &c., department the contributions were excellent and varied. Amongst those with whose names our readers are familiar, we may particularize the manufactures of Messrs. Johnston, Brothers, mediæval iron and brass workers, 190, High Holborn, who are truly eminent in their art; Messrs. Hart & Son, in same line, who had a magnificent display of church ornaments and furniture, monumental brasses, &c.; Ransomes' ornamental works in patent siliceous stone (already alluded to at some length in this journal);[*] Arrowsmith's (of 80, New Bond-street) specimens of solid parquetrie floors, as executed extensively throughout the kingdom, and in Ireland at Old Connaught, Bray, for Phineas Riall, Esq.;[†] at Col. Taylor's, Ardgillan, Balbriggan, &c.; Maw & Co.'s, Minton's, and Hollins' tiles; Cumberland Part's patent cement, &c. Mr. Pierce, of Jermyn-street, Regent-street, exhibited his pyro-pneumatic and fire lump stove-grates, also his fresh-air cottagers' grate, for warming two rooms simultaneously and with only *one* fire. This manufacturer stands pre-eminent in his branch, and has devoted himself to it with an ability and energy truly commendable. As already stated, there is one of these handsome and useful articles to be seen at the National Bank. The establishments represented may justly be proud of their displays.

MORE ABOUT THE ULSTER HALL.

The following correspondence, between a competitor and the company, on the subject of the recent competition for the Ulster Hall, has been forwarded to us for publication by Mr. Robert Young, a Belfast architect, who states that "he read with much pleasure our leader in April number" relative to this affair.

13, Donegall-place, 3rd April, 1860.

Gentlemen,—In justice to myself and others I have to request your reply to the following queries:—1st, did any Belfast builder of respectability estimate the cost of erecting the new Hall and other buildings connected with it, according to the designs to the authors of which you have adjudged the prizes of £50 and £25? 2nd, if so, the name of the builder, and the amount for which he would have undertaken to execute each design? I should be much obliged by an early reply, and remain, respectfully yours, R. Young.

To the Directors of the Ulster Hall Company.

Ulster Hall Company (Limited), Belfast, 5th April, 1860.

Sir,—In reply to yours of the 3rd instant, I am instructed by the Directors to say that, in accordance with their "Instructions to Architects," they did satisfy themselves that they could effect a contract for the execution of the work at the price estimated by the architect of the design selected.—I am, Sir, your obedient servant, John Dunn, Jun., Secretary.

Robert Young, Esq., Donegal-place.

13, Donegal-place, 9th April, 1860.

The Directors of the Ulster Hall Company,

Gentlemen,—I beg to acknowledge having received through your Secretary a note dated 5th instant, purporting to be a reply to my letter of 3rd instant. You cannot surely imagine that I can accept it as in any sense a reply to my questions. The *extraordinary* discrepancy between the lowest tender for the buildings and the sum to which we (competing architects) were strictly limited by your stipulations has naturally given a very strong impression, both to the architects concerned, and to a large number of the shareholders, that the design you have chosen was not at the *right time* tested by the estimate of a competent builder. I have respectfully to ask your consideration of my letter of 3rd instant, and the favour of a *categorical* reply to the queries contained in it, or a *distinct refusal* to give the information sought. I ask this mainly on the ground of justice to myself and other architects, who spent time, thought, and money, to no inconsiderable extent, for your benefit, on the strength of perfect equity being observed in making the choice of plans. But I believe that, as a shareholder of the Company, I have also a right to the information.—I remain, gentleman, very respectfully yours, R. Young.

Ulster Hall Company (Limited), Belfast, 12th April, 1860.

Sir,—I am instructed by the Directors to acknowledge the receipt of your note of the 9th instant, and in reply refer you to their note of the 5th instant, which, in their opinion, conveys all the information required, and that they must therefore decline entering into further correspondence on a subject which is finally, settled.—I am, Sir, your obedient servant,

John Dunn, Jun., Secretary.

Robert Young, Esq., Donegal-place.

[Communicated.]

The delay in commencing this work is consequent on the company's issue of new shares, to increase their capital—the original capital of £10,000 being found inadequate. Tenders were taken in from builders for the new hall, of which the lowest was about £13,000; but this included accommodation and works not contemplated in the competition, the omission or postponement of some of which supplemental works it was ascertained would bring the tenders under £10,000 (including £2,000 worth of piling of foundations).

When the committee met to receive the reduced estimate, the majority were in favour of an increased capital and the execution of all the works tendered for, and they decided on bringing the matter before a general meeting of the shareholders, and at the latter meeting an amateur architect intruded fresh designs on their attention. But the committee are merely waiting to get up the additional capital, believing that the design they selected in competition could have been carried out as originally intended, but they feel now that as the competition is over, the premium paid, and Mr. Barre appointed architect to the company, they are at liberty to do the best they can, and to act as they please in the matter.

There is one thing the committee might have done—namely, had the builder at work on their present capital, and saved the building season, which is now passing by, either by ordering the piling and foundations, or the shell of the building, all of which would have been within their present capital.

KERFS AND COGITATIONS.

BY A CRAFTSMAN.

NO. II.—THE ANTIQUE WORKERS.

In the Ogham inscriptions of Ireland and the hieroglyphics of Egypt may be interpreted many a wondrous phase of the constructive intellect of the past. The Sphinx still keeps its eternal silence while truant or traveller pauses or passes on, from out its mouth no oracles comes forth now—no weird-like chaunt rings out on the midnight welkin from Druids altar or monumental cairn. The two enigmas of the world are still unsolved—pyramids and pillar towers; but in papyrus or parchment live not the spirit we apostrophise, the genius by which we are consecrated. Antique craftsmen, heroic souls, rivals they might have and had, ambition might be theirs and was, but it begot no ephemeral production, no uncouth form, no crude conception hastily worked out for selfish adulation or mercenary recompense. They loved their art—nay, they adored it; painter and poet, sculptor and mosaic worker, architect and craftsman, all alike. The accumulating study of a lifetime was often concentrated for the realization of one triumph, which was to become the *chef d'œuvre* of their fame. See, in their efforts in this first of all the arts does there not swell forth an embodiment of all that is bright, grand, and glowing in nature, or strong, perfect, and proportional in man—in each classic order an entity, in each entity a unity. In the unhewn stone the worker saw the *mirage* of his brain slowly developing and quickening with the spirit of an inspiration; spiritual and godlike he seized the instrument of his craft, and rested not till he achieved an immortality. Was there not something spiritual, something above the gross materialistic grovelling of to-day, enlivening the genius of Angelo, when at upwards of sixty he could wield the chisel with the energy of youth—sending the splintered marble like a hail-shower scintillating through the sunshine of his studio—intuitively outlining into form the virgin block at each blow? It was ever thus with the antique mind. Prophet-like their works bear the *impresse* of their inspiration. Through many a year they toiled, and toiled, and toiled; old age might creep, but, if it found them hoary-headed, it found them still faithful; years of pent up study accelerated their day-dream, the consummation wished for, but, alas, it also brought its penalties and pains. All hail, ye shades of immortality; the chaplet that should encircle the living brow became the laurel wreath of the tomb—the extatic "Eureka" of Pythagoras breathed their first living joy and their last dying utterance.

C. C. H——y.

[The Editor should feel gratified by an interview with his unknown but *valued* contributor.]

Notes of New Works.

A testimonial is to be erected at Armagh to the memory of the late Rev. Cosby Stopford Mangan.

A new Roman Catholic church is to be erected at Breedogue, near Frenchpark, Co. Roscommon.

It has been resolved to erect a suitable memorial to the late Sir Robert Ferguson, Bart.

St. Vincent's Male Orphanage, at Glasnevin, is progressing towards completion, the main building being now roofed in. The *Freeman* thus describes particulars:—"Finding that the establishment at Monnt Brown was quite inadequate to accommodate the numerous applicants, the committee commenced the new house at Glasnevin, where they have leased from Captain Lindsay six Irish acres of land in a most advantageous situation. Plans were advertised for; a large number were sent in, and the committee decided upon adopting that by Mr. John Stirling Butler, architect, of Hume-street. In December last the foundation stone of a section of the building was laid by his Grace the Archbishop, who placed £500 at the disposal of the committee as a beginning for the £4,000 which the portion of the orphanage then commenced would cost. The Duke of Norfolk sent the munificent contribution of £300. More than £3,000 was received, and, as we have stated, the first portion of the pile is rapidly advancing to completion. It already forms a striking ornament to the suburb, in which it keeps suitable companionship with the Hospital of the Mater Misericordiæ, the Deaf and Dumb Asylum at Cabra, and the St. Peter's Church and Schools, Phibsboro, all in sight. The several features of the building are evidently Italian in character. At one extremity is a handsome arcade, with stone stairs leading up to the schools, and about the centre is the principal entrance porch leading to all other departments, which, together with the gables, open niches, bell-cot, and the capping of chimneys, form characteristic features of that style of architecture. The materials employed in the construction of the works are hammered black stone and chiselled granite. The present wing, whan completed, will be capable of accommodating 120 boys. The dormitories are well ventilated and spacious, and, from the omission of plastered ceilings, a good deal of extra height is obtained. Both the architect and the contractor (Mr. P. Meares) have given the utmost satisfaction to the committee in the performance of their respective works. It will be one of the cheapest of its class ever erected in Dublin."

Tenders have been sought for recently from builders for farm buildings and other works, to be erected on the property of his Grace the Duke of Leinster.

Messrs. Graham Lemon, & Co., have taken the house No. 61, Grafton-street, corner of Tangier-lane, and are re-fronting and otherwise improving it.

We understand that Mr. Lennon, of Abbey-street, is about building on Church-road, adjoining Mr. Bolland's property, and opposite that of Mr. Philip Brady, where, as already stated, works are in progress, Mr. Lyons, architect.

The Farmers' Club are about having alterations made at their house in Sackville-street, plans and estimates for which have been submitted.

Messrs. Todd, Burns, and Co. have made very extensive additions and improvements to their establishment, under the direction of Mr. E. P. Gribbon, the company's architect, during the past few months; they are now about being completed, and are worthy of inspection. Mr. S. H. Bolton is the builder.

Messrs. Cannock, White, & Co. have taken the house No. 8, Henry-street, belonging to Mr. Lowe, paper stainer and painter, and are about adding it to their concerns, which will now occupy either side of Nos. 9 and 10, the warehouse premises of Messrs. Talty, Murphy, & Co. Where will this ever-growing monster house stop?

It is in contemplation to extend the College of the Immaculate Conception at Knoctopher.

A Catholic Church is to be erected in Magherow, and the Earl of Dunraven has subscribed £20.

Reviews.

Brief Sketches of Booterstown and Donnybrook (Co. Dublin). By the Rev. B. H. Blacker. Dublin: George Herbert.

WOULD that the incumbents of all the suburban parishes were actuated by the same truly laudable zeal in research after the beautiful in art and the venerable in antiquity as is the author of the little work before us. Were it so, much that is now veiled to the public eye would be brought to light,—our ancient relics would have a hand, however feeble, raised to save them from destruction, the historic memories of our suburbs—and which of them has not some of peculiar interest?—would become popularly familiarized, not as they are at present, clouded in obscurity alone penetrable by the *savans*, and localities now disregarded, because forsooth they are not embraced in the circle of the fashionable *lounge*, would have their claims for appreciation fully and fairly set forth. The chronological tables of the events known in connection with the parishes treated of materially enhance the value of this book, and afford an excellent example for parochial historians. The *animus* of the author demands repect, and he has fulfilled his mission ably.

A House for the Suburbs, Socially and Architecturally Sketched. By Thomas Morris, Architect, M.R.I.B.A. London: all Booksellers.

FEW authors are equally happy in their powers of delineation with both pen and pencil. Such, however, is the distinguishing feature of the work before us; the social sketching of the domestic circle in suburban districts,—"the book club," "family dinners," "coteries and soirees"—being graphic, replete with poetical expression, and presenting relief in the foreground to the more matter-of-fact and rigid outline of the architectural subject; the illustrative department, including the frontispiece—a general view of "a house for the suburbs"—beautifully executed, and designed in a manner displaying much skill and taste, plans of same, and of a Pompeian house, a mansionette, a compact house, and semi-detached houses, accompanied with practical remarks, all forming a pleasing and instructive little volume.

Referring to improved facilities of intercourse, the author says: "Thanks to the modern genius of speed and the science of the rail, there is a wholesome future in store for us;" and to the inducements for a suburban life, that "there is a continuous influx of provincial recruits, who never lose their pastoral associations, and, though engrossed for a while with novelty and excitement, return with the pure affection of an early love to homes" exempt from public haunts, "and they must hail the daily change from worldly care to nature's quietude, the healthful alternation of activity and ease, now rendered practicable as a movement of promise for body and mind for to-day and hereafter."

A Practical Treatise on the Construction of the Turbine, especially designed for the use of Operative Mechanics. By William Cullen, Millwright and Engineer. London: E. & F. N. Spon, Bucklesbury.

FEW countries are so peculiarly blessed in abundant and regular water supply as Ireland. True we have our share of mountain torrents, but even these are not at all beyond the reach of science. Still, like our fisheries and other means at our disposal for increasing the wealth of the population, our water supply is let to run waste, and few countries of the old world appear so indifferent to the enormous powers thus left to lie dormant, or waste their strength on the pebbly beds of their course. Since the people of this country have turned their attention to the science of agriculture, they have become aware of the importance of the use of "power machines"—but where have they sought the power? How many instances, in the entire length and breadth of the land, can we show where the farmer has used the power lying under his feet? Do they not all send elsewhere for expensive, most unwieldy, and in some instances remarkably ill-shaped machines, at great cost and inconvenience, to do what their familiar trout stream could effect for them without any of these drawbacks. In round numbers, a turbine, costing, fixed in place, £70, will perform 250 revolutions in a minute, at a nominal power of four horses, and a head of water of 16 feet. But now comes the question—What is a turbine?

We confess that from seeing these machines on the continent, we are ourselves aware of the shape and working of the machine, but we were long at a loss to convey our ideas to many who had written to us on the subject, or to recommend any work which would not be of too high an order to convey a mere popular notion. We, therefore, gladly welcomed Mr. Cullen's book on turbine wheels; it is what our readers and ourselves had long desired—namely, a thoroughly practical work, in which the writer lucidly and fully conveys—with a modesty ever the accompaniment of true genius—the results of years of labour in the cause.

To arrive immediately at the fountain-head of the principle of turbines, Mr. Cullen visited the Continent, but had considerable difficulty in gaining admission to the works or mills where these machines were at work. Having, however, mastered many obstacles, he returned home, and laying the results of his labours before Mr. MacAdam, the proprietor of one of the Belfast foundries, that gentleman requested Mr. Cullen to supply him with working drawings of a turbine, from which a wheel was constructed for a fall of 21 feet, and erected at the bleach-mill of Messrs. Barklie & Co., of Mullamore, near Coleraine, which, on several occasions, worked with 9 feet of back-water with the greatest regularity. After forwarding the erection of several others, Mr. Cullen again visited France, and being fortunate in his researches than formerly, and the result of all has been the work that we here have the pleasure of noticing. It contains seven comprehensive plates, specially designed for the use of operative mechanics, as also several tables and formulæ of great importance; and we would say to any of our agricultural friends who may not have as yet obtained the work, that they ought not to be longer without it.

Official Railway Handbook to Bray, Kingstown, and the Coast, &c. By G. R. Powell. Dublin: M'Glashan & Gill; London: Simpkin, Marshall, & Co.

This is an excellently compiled little work, and embraces a variety of useful and interesting information, such indeed as might be read with pleasure off the rail as well as on it. It opens with prefatory remarks, directed to the tourist, relative to the facilities afforded by the Dublin and Wicklow Railway (which, we may remark, is one of the best conducted and certainly the most picturesque line in Ireland), the beauties of Wicklow, the mountains, quotations from English and French journals upon Irish scenery and natural resources, &c. A handy reference map, showing the connection between the Counties of Dublin and Wicklow with rail, and other routes thereon, is also added. A sketch of "Sunny Bray," with a day at Quin's (of "universal renown"), the Head, Dargan Terrace and Esplanade; the Turkish Baths, Presbyterian Church, the Station, Breslin's, Shankhill house, Kilruddery, Hollybrooke, and other buildings—with particulars of which our readers are, through the Dublin Builder, more or less familiar—is pleasingly given. The author has not forgotten to award his meed of approbation to that excellent local (especially) and national benefactor, William Dargan – an evidence of good taste which commands appreciation. The Dublin and Kingstown branch, and the various objects of interest along its route—Kingstown, with its piers, jetty, club houses, &c.—are sketched with graphic accuracy; and the rambles to the Dargle, Enniskerry, Powerscourt Demesne and Waterfall, Scalp, Glendalough and the Seven Churches, the Sugarloaves, Vale of Avoca and Meeting of the Waters, Poul-a-Phuca, Devil's Glen, Delgany, Glen of the Downs, &c., complete the survey, which is artistically delineated. The value of the illustrations would have been enhanced materially by the adoption of a somewhat larger scale; nevertheless they are an acquisition. and the work is very creditable to all concerned.

Miscellaneous.

Sale of Building Materials.—One of the most extensive sales of building materials that has taken place in Dublin for many years was the auctioning of the old business concerns in Pill-lane, which are being thrown down for improvements in that locality. Some of the goods (bricks especially) fetched fabulous prices, while carpentry-work went proportionately low.

"Raising the wind" by Lottery.—This practice—and in the matter of church-building too, which is worthier of a more laudable stratagem to procure the wherewith—has prevailed of late to such an extent that the authorities have conceived it their duty to interfere, and very properly. The Crown-Solicitor put the *quietus* on the proposed lottery on behalf of St. Saviour's Church in this city, and we trust that his *confreres* in Belfast, Limerick, &c., where Grand Prize Drawings are announced, may adopt a similar course. Such an alternative may be comparatively legitimate in public amusements, "to draw a house;" but, where associated with religion—be the denomination what it may—it institutes a mockery, and converts the temple of God into a speculative Bourse. If the voluntary contributions of the faithful be not adequate to the expenditure for magnificent edifices, better build them of less pretentious character than commence on a scale demanding such a *dernier resort* to extricate the promoters from a difficulty.

Insurances on Houses of Worship.—The inhabitants of St. Mary's parish have applied to the Ecclesiastical Commissioners of Ireland to ascertain their co-operation, and to what extent, in effecting an insurance on the church. The letter was referred to the Board of Inland Revenue, who, it is said, have in many such instances remitted the duty. The rector suggests a valuation, and an undertaking from the Commissioners of responsibility to a certain amount in case of fire, the churchwardens insuring for the remainder. Mr. Hancock, at George's vestry, referring to same subject, remarked that "the Ecclesiastical Commissioners, with no funds of their own, are in the position of a small insurance company, and if they set aside that sum they cannot pay the full amount. There are two thousand churches in Ireland, and that number at 1s. 6d. per cent. would only give £1,300 for each church. It is shown that if the Commissioners set aside a fund they could never out of it meet such a large demand as £29,000 or £30,000 for one church; therefore it should be insured over. This church (George's) is stated in *Thom's Directory* to have cost £90,000; Gardiner-street chapel cost £18,000, Westland-row £13,000, and King's Inn, £3,500. The insurance of the Commissioners would be only about £1,400 on each church."

New Landed Estates Courts.—The new buildings containing the Landed Estates Courts and the offices connected with them were opened yesterday for public use. The site, as is well known to all whose business leads them to the Four Courts, is at the rere of that building, the new structure being on the western side of the Attorneys' and Solicitors' rooms and the Coffee-room, so as to correspond to the range containing the Bankruptcy and Insolvency Courts and the Masters' Offices, which lie on the opposite side. The buildings have been erected in accordance with designs by Mr. Owen, architect to the Board of Works; and the entire contract was held by Mr. Meade. The original estimate was £16,800, to which £2,500 was afterwards added for extras. The lower and the third storeys of the building are occupied with offices. The middle storey contains two courts, besides private apartments for the judges and offices for the examiners. There is a third temporary court below stairs. The design of the buildings, and the style in which the interiors are finished, are such as to combine with utility a sufficient amount of ornament to relieve the eye and to impart a dignified aspect to the place where an important branch of the public business is transacted. Judges Longfield and Hargreave have sat in the new courts, and disposed of business.

Milwaukee Academy of Music.—The new hall is stated to be one of the most tasteful and elegant in the country, but seats only about 1,000 persons.

Improvement of Ballinasloe.—The works projected by the Town Commissioners will only cost £550, but it is a beginning. Mr. Sanders is engaged to plan and superintend them.

Stencil Printing.—The adoption of this system saves much time and labour to the daughtsman, and money to the employer. Any number of sheets of drawings may be fully printed on—in a decorative manner if required—by stencil plates, and in one-tenth the time usually occupied by hand. We can testify to these facts by experience, and have found the plates supplied to our order by Messrs. Braham and Co., of London, distinguished for excellence of workmanship, and variety and suitability of design for architectural and engineering purposes.

Architecture in Ballarat.—Mr. C. D. Cuthbert, architect (late of Ballast Office, Dublin) has been declared the successful competitor for the new town hall; his design comprising externally a principal elevation extending 50 feet, with a tetrastyle Ionic portico, and an elevation towards Armstrong-street displaying 22 windows. Internally there is a great hall for public meetings, balls, &c., situated at the rere; as also a police court, library, museum, and various other apartments. Estimated cost, £15,000, in granite. Mr. Cuthbert's card model submitted to the committee is very highly spoken of. The second and third prizes have been respectively awarded to Messrs. Backhouse and Reynolds, of Geelong, and Mr. C. Porter. The new Chinese joss house on the Golden Point is said to testify favourably to the skill of Chinese artizans. The façade is decorated with animals from a cock to a lion with two tails, and over the door are the words "Chinese chapel" in characters. The interior is richly adorned with carvings, and the walls hung round with mottoes which cost sums varying from £8 to £12 each. At the extremity of the building is a dais on which Quang Kong, the Chinese god, is seated cross-legged, with a perpetually burning lamp before him, and three grim-visaged figures above his head. A devotee has to pay £1 5s. for privilege of admission. Total cost of building, £600. The Botanical and Zoological Gardens are being handsomely laid out with new walks, pavillions, conservatories, houses for the animals, artificial islands, bowers, benches, grottoes, &c. They are open on Sundays, and the average number of visitors is 7,000. A new hotel is being erected in the main road; Mr. F. Korn, architect.

BUILDERS' IRONMONGERY, AT REDUCED PRICES.

THOMAS HENSHAW & CO.,

5, CHRIST CHURCH PLACE,

BEG to call attention to their extensive, varied, and well-selected Stock of Ironmongery in all its different branches. It consists of Parlour, Drawing-room, and Bed-room Grates; Kitchen Ranges, Cottage Ranges, Sash Weights; Iron Rim, Mortise, and Stock Locks; Hinges of all descriptions; Wrought and Cut Nails, Eave Gutters, Down Pipes and Fittings, Metal Skylights, Ventilating Bricks; Cast-iron Chimney-pieces, with and without Grates; Rabbit Traps, Fox Traps, Galvanized Wire Netting, Fencing Wire, Sheet and Perforated Zinc, Sink Traps, Furnace Doors and Frames, Hot Air and Plain Stoves. Also on Sale, Saunders' Patent Cooking Range, *the* most economical Cooking Apparatus of the day.

Manufacturing and General Ironmongers and Tool Warehouse—81, MIDDLE ABBEY-STREET.

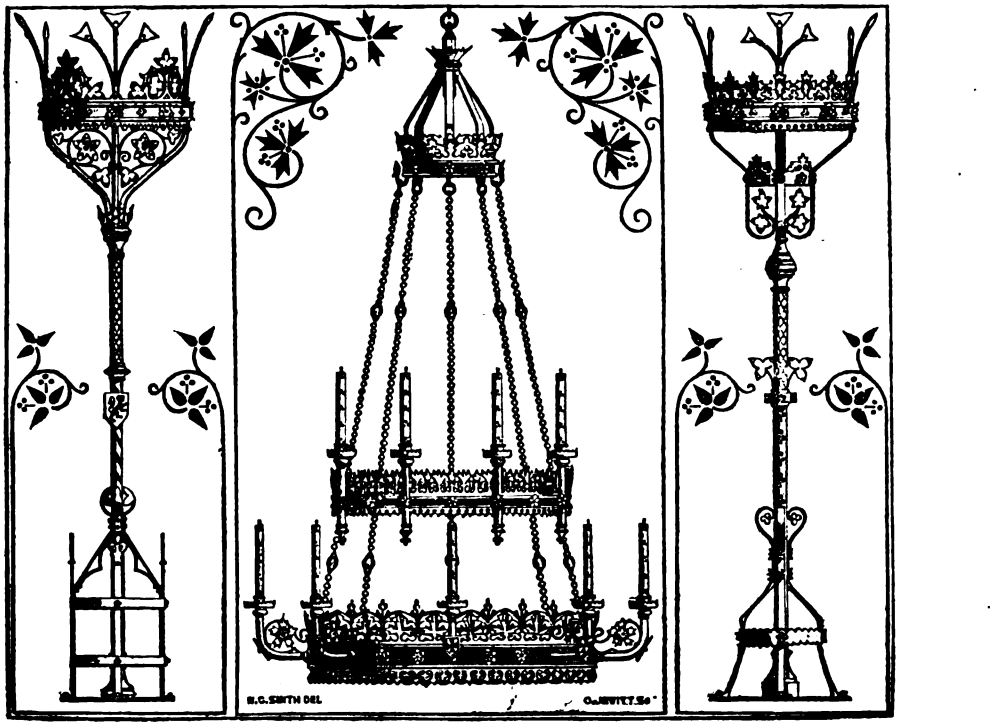
Spade, Shovel, and Tool Works—CLONSKEAGH.

Agents for Perry's Patent Fire-proof Safes; quality considered, they are *the* cheapest in the market. Builders are invited to inspect our Stock previous to purchasing.

5, CHRIST CHURCH PLACE, DUBLIN.

JOHNSTON BROS

MEDIÆVAL METAL WORKERS & GAS FITTERS



MANUFACTORY, 190, HIGH HOLBORN, LONDON.

GEORGE PRICE
WARRANTED
PATENT
212
FIRE PROOF & THIEF PROOF
WOLVERHAMPTON

PRICE'S DOUBLE PATENT FIRE-RESISTING and BURGLAR-PROOF SAFES, containing all the Improvements under his two Patents of 1855 and 1859, and fitted with his "NE-PLUS-ULTRA" LOCK, are Sold Retail from Ten to Thirty per Cent. under the Safes of other first-class Makers.

PRICE'S PATENT IRON DOORS and FRAMES, for Strong Rooms and Fire-proof Closets. The size, 6 feet by 2 feet 6 inches. Both Fire-proof and not Fire-proof always in stock.

PRICE'S New Patent "NE-PLUS-ULTRA" LOCK is warranted unpickable against every known mode of picking; and from its simplicity of construction, nothing but absolute violence can throw it out of action; and the extra strength of its parts renders it the most durable Lock extant. Sold Retail, with Seven Acting Levers, Twenty per Cent. under other first-class Locks with but Six Levers.

Illustrated Price Lists of Safes and Locks (with Testimonials), free, on application to the Patentee and Manufacturer, Cleveland Safe and Lock Works, Wolverhampton.

"PHOTOGRAPHIC ETCHING."—A simple and useful application of Photography, requiring no camera nor expensive apparatus, and practically useful to architects and others in multiplying copies of plans and drawings generally.

W. STRUDWICK will send his Book of Instructions on the subject (post free) for Eighteen Stamps. Personal instructions if required.

2, BOLTON-TERRACE, NEWINGTON, LONDON, S.

IMPERISHABLE TESSELATED PAVEMENTS.—H. SIBTHORPE AND SON, Agents to Maw and Co., are prepared to supply Designs for Floors of Churches, Conservatories, Entrance Halls, and Passages, with proper Workmen to lay them in any part of Ireland.

Various specimens may be seen at their Warerooms,

11 AND 12, CORK-HILL, DUBLIN.

SHEILS AND SCOTT are further enlarging their new and extensive PREMISES,

29, WESTMORELAND-STREET.

Iron Founders, Plumbers, &c.

TO RAILWAY CONTRACTORS, BUILDERS, QUARRYMEN, ETC.

EVERY description of SHOVELS, SLEDGES, HAMMERS, PICKS, Steel, Crab Winches, PULLEY BLOCKS, CHAIN; MASON'S, SMITH'S, and WORKMEN'S TOOLS of all kinds.

THOMAS HENSHAW & CO.,
HARDWARE MERCHANTS AND MANUFACTURERS,
5, CHRIST CHURCH PLACE,
AND
81, MIDDLE ABBEY-STREET, DUBLIN.

CHEAP IRONMONGERY.

A WELL ASSORTED STOCK of BUILDERS' and FURNISHING IRONMONGERY, also GARDEN and WORKMEN'S TOOLS of all kinds, which are offered at the lowest price of the day, for *Cash*, at

EGGINTON & CO.'S (LATE FITZHENRY'S),
No. 160, CAPEL STREET, DUBLIN.

BEAM & SCALE MANUFACTORY and GENERAL IRONMONGERY STORES,
MOUNTRATH-STREET, PILL-LANE, DUBLIN,
SAMUEL GATCHELL and SONS
Continue to carry on their business as heretofore in the above Concerns.

NEW BALANCE ROLLING BRIDGE.
KENNY'S PATENT.

The undersigned beg to call the attention of Engineers and the Public to the above description of Opening Bridge, as now being constructed for the entrance to the St. George's Dock, Custom-house Quay, Dublin, for the Board of Works, which will be found superior to the ordinary Swivel Bridge, both in point of simplicity of Construction and Cost.

Plans and Specifications furnished, and Licenses granted on application to

TURNER AND GIBSON,
PROPRIETORS AND MANUFACTURERS,
HAMMERSMITH IRON WORKS, BALL'S-BRIDGE, DUBLIN.

IRON CASTINGS—CASTINGS of every description for Gas and Water Companies, Millwrights, Builders, Plumbers, &c., made at
SEVILLE IRON WORKS, SEVILLE-PLACE, DUBLIN.

WILLIAM TURNER,
OXMANTOWN FOUNDRY & IRON WORKS,
103, NORTH KING-STREET, DUBLIN.

Cast-Iron GIRDERS, Plain and Ornamental PILLARS, Moulded and Plain GUTTERS, Tank Plates, Gas Retorts and Pipes, Kitchen Range Work, Millwright, Castings, Balconies, Brackets, Staircase Ballusters, etc., supplied. A large variety of Models for the above in stock.

CLOSE FIRE KITCHEN RANGES.
GODDARD'S PATENT ECONOMICAL COOKING APPARATUS.
JOSHUA EDMUNDSON AND CO.,
Are Sole Agents for the above Ranges.

Their chief advantage is economy in fuel, no portion of the heat generated being allowed to go to waste, and is all available for Cooking, which occupies a shorter time, and is done much more effectually than by the ordinary process.

J. E. and Co. are manufacturers of THE PATENT GAS APPARATUS, for Lighting Gentlemen's Country Mansions, Mills, Manufactories, Country Towns, &c.

HOUSE FURNISHING IRONMONGERS, GAS FITTERS, AND GAS ENGINEERS,
34, 35, & 36, CAPEL-STREET, DUBLIN.
Agents for Milner's Fireproof SAFES and BOXES.

WROUGHT IRON TANKS.

THESE USEFUL ARTICLES are suitable for every place where a supply of water is necessary. Their superiority over Cast Iron, Lead, or Stone is manifest, from the fact of their being much lighter, also completely obviating the difficulty in staunching, so objectionable in all Cast Iron Tanks. They are made in every shape and form, to suit the places where they are to be fixed.

Prices from 3d. to 5d. per Gallon, the larger sizes being cheaper in proportion.

HODGES AND SONS,
MANUFACTURING IRONMONGERS,
16, WESTMORELAND STREET, AND 20 & 21, ASTON'S QUAY, DUBLIN.

N.B.—Force Pumps, Baths, and all description of Hydraulic Plumbing work executed on the most improved principle.

ROBERT MACLAREN & CO.,
EGLINTON FOUNDRY, GLASGOW,
Manufacturers of all sizes of CAST-IRON MAIN PIPES, for Gas or Water, by an IMPROVED PATENT.
GENERAL IRON FOUNDERS, GAS ENGINEERS, and WROUGHT-IRON TUBE MAKERS.

Statuary, Marbles, Cements.

ELLIS AND CO.,
PORTLAND CEMENT MANUFACTURERS,
MALONE MILLS,
BLACKSTAFF ROAD, BELFAST.
Sole Agents in Dublin,
Messrs. CAROLIN AND EGAN, 20, EDEN-QUAY.

THE M'ANASPIES, Practical, Plain, and Ornamental Stucco Plasterers, Scagliola and Figure Artists, Staturists, and Asphalte Workers, &c.
PHOTOGRAPHIC AND STATUARY GALLERIES,
31, GREAT BRUNSWICK-STREET, DUBLIN.

CEMENT—ROMAN, PORTLAND, MASTIC, & PLASTER of PARIS.
JOHN CARRICK, 5, MARY'S-ABBEY.

CHIMNEY PIECES—in Italian, Belgian, Irish, and English Marble; Enamelled Slate, and Cast Iron: suitable for Drawing-rooms, Dining-rooms, Bed-rooms, &c. A very large Stock to select from. MAURICE BROOKS, Sackville-place, Dublin.

BEST CEMENTS.

ROMAN CEMENT, PORTLAND CEMENT, and PLASTER PARIS STORES,
10, SIR JOHN'S-QUAY, DUBLIN.

GEORGE HOLMES and Co. are constantly supplied with the above materials of genuine quality, direct from the best manufacturers. Also Sewerage Pipes, Junctions, Bends, &c.

TO ARCHITECTS, BUILDERS, ETC.

JAMES HOGAN AND SONS,
PLAIN and ORNAMENTAL STUCCO PLASTERERS,
CEMENT WORKERS, &c.,
168, GREAT BRUNSWICK-STREET,

Beg leave to state that they will furnish every description of Plaster Ornaments for the Decoration of Cornices, Centre Pieces for Ceilings, at Moderate Prices and on the Shortest Notice.

Country Orders strictly attended to.

BARHAM'S RENDERING CEMENT.

FOR internal and external Plastering, Scagliola, &c.—Walls covered in a single working.—May be Painted or Papered on within 12 hours.—Sold by weight.

MANUFACTURED BY
ALFRED G. BARHAM,
CEMENT AND PLASTER WORKS,
BRIDGEWATER.

TESTIMONIALS.

[Copy.] Five Ways, Birmingham, March, 15, 1860

Mr. BARHAM.—SIR—After several trials in various ways, both inside and out, of your cement, I can confidently certify for all you state as to its quality.

I have both papered and painted on the same immediately, and find neither color or paint in the least affected. I am, Sir, yours truly,

(Signed) J. CRESSWELL.

[Copy.] Decorative Painting, Gilding, and Paper-hanging Establishment, 119, Duke-st., & 18, Parr-st., Liverpool. Jan. 17, 1860.

SIR—I have much pleasure in bearing my testimony to the good qualities of your "Rendering" Cement. I find that paint will stand well upon this Cement, after being allowed only three or four days to dry.

In another case a wet piece of this Cement was papered with a delicate Pink Glazed Paper, and I find that neither color nor glaze has sustained injury.

Yours truly,
(Signed) p pro ALEXANDER WHITE.
RICHARD S. WHITE.

(Copy.) Bridgnorth, Oct. 25, 1859.

DEAR SIR—We have tried your sample of "Rendring," and find it more than justifies our anticipations. We have tried it raw as a Cement for external work in a very exposed position in a Church Tower, to fix in some Iron Cramps in lieu of lead, and find it answer perfectly; also for cornices; also mixed with hair mortar as gauged stuff for forcing work; and in several other ways. When anything stirs, we will apply to you for some more, as we find it better and cheaper for gauged work than any we have ever had.—With respects, Sir, we remain yours very truly, (Signed) JOHN PICKARD & SON.

CENTRAL DEPOTS.

LONDON—A. J. TATHAM, 14, South-wharf, Paddington Basin, W., and Purfleet-street, Earl-wharf, Blackfriars, E.C.

LIVERPOOL—GEORGE F. CHANTRELL, 6, 8, and 31, Hatton-garden, 60, Soho-street, and Bank-quay, Warrington.

Plaster of Paris.
Roman Cement.
Portland Cement.
Patent Mastic Cement.
John's Patent Stucco Cement.
Keene's Patent Marble Cement.

Of the best quality, to be had of

SALMON RICE, AND CO.
3, ANGLESEA-STREET.

Also Crown, Sheet, and Plate Glass; Fire Bricks, Tiles, &c.; Painters' and Plasterers' Brushes.

Gypsum for Agricultural Purposes

STEAM MILLS AND MANUFACTORY—CROWN-ALLEY.
Established, A.D. 1780.

Oils, Colours, Glass, &c.

MANNIN'S Wholesale and Retail DRUG, OIL, COLOUR, and GLASS WAREHOUSE,
2, GREAT BRUNSWICK-STREET.
(near D'Olier-street.)

Cattle Medicine of all kinds.

N.B.—Every article is warranted genuine, and at the lowest price.

PROPAGATING GLASSES, & GARDEN CAPS for covering Flowers. A large Stock at
JOHN CARRICK'S, 5, MARY'S-ABBEY.

UNION PLATE GLASS COMPANY.

The very beautiful article of Plate Glass, manufactured by this company, can be had at the price of the lowest in the market, shipped to any Port in Ireland.

H. SIBTHORPE AND SON,
Agents for Ireland,
11 AND 12, CORK-HILL, DUBLIN.

TABLE GLASS, BOHEMIAN GLASS, PARIAN VASES, FIGURES, & HYACINTH GLASSES.
JOHN CARRICK, 5, MARY'S-ABBEY.

ROOM PAPER, in great variety, at MAURICE BROOKS', SACKVILLE-PLACE, Dublin.

GLASS SHADES—ROUND, OVAL, and SQUARE, with Gilt, Black, and Inlaid Stands.
JOHN CARRICK, 5, MARY'S-ABBEY.

JOSEPH O'LEARY, DECORATOR, Painter, Room Paper Manufacturer, and Dealer in Window Glass, and Laminated Lead for Damp Walls, No. 1, TEMPLE-LANE, Dame-street.

WINDOW GLASS—CROWN, SHEET, PLATE, POLISHED, AND ROUGH.
JOHN CARRICK, 5, MARY'S-ABBEY.

PLATE GLASS kept in Stock and supplied immediately, whereby the usual delay in ordering from the Manufactory is avoided.
MAURICE BROOKS, SACKVILLE-PLACE, DUBLIN.

Publications.

A HANDY BOOK on VILLA ARCHITECTURE. By C. WICKES, Architect. Five designs, thirty plates, with outline, specifications, and estimates, royal 4to (12½ in. by 10 in.), half morocco, gilt edges, &c., &c. £1 7s.

"An elegant quarto volume. The plans are very well arranged, and the whole may be regarded as decidedly a Handy Book."—*Builder*, October 29, 1859.

"The plans are on the whole conveniently arranged, and merit attention. . . . . It is a handsome volume."—*Building News*, Nov. 4, 1859.

London: THOMPSON and Co., 111, Strand, W.C.

TO TIMBER MERCHANTS AND BUILDERS.
Will be ready on the 15th of January, 1860,
Price 7s. 6d.

THE CALCULATOR; or, TIMBER-MERCHANT'S and BUILDER'S GUIDE.
By WILLIAM RICHARDSON & CHAS. GAKE, of Wisbech.

Containing about 500 pages, 12mo. Should be on the desk of every one connected with the trade, and will be found invaluable for casting and checking invoices, etc., both in reduction of quantity and money, with other information. Order early of

KELLY & CO., OLD BOSWELL-COURT, STRAND, W.C.

Demy 8vo., 7s., Plans and View.

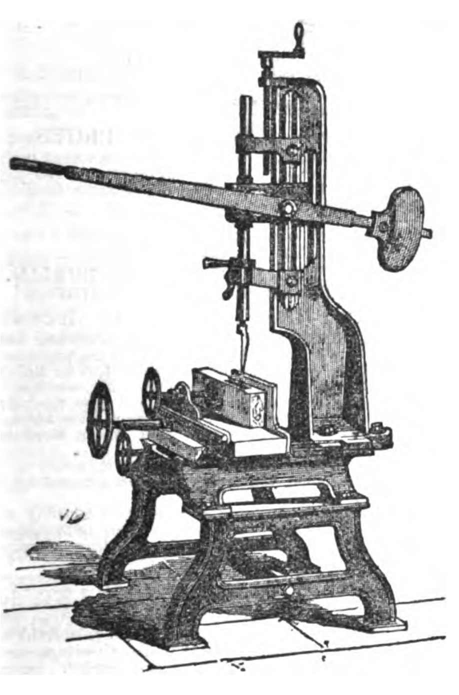
A HOUSE FOR THE SUBURBS.
Socially and Architecturally sketched by THOS. MORRIS.

"Full of valuable information and suggestions. It is not every man that can make a work on such a practical subject interesting reading; but Mr. Morris may certainly claim credit even in this respect."—*Literary Gazette.*

London: Simpkin, Marshall, & Co.

GALLON AND BEAN, LEEDS,

Cut & Wrought Nail Manufacturers, & Hardware Merchants,



RESPECTFULLY request all BUILDERS, CONTRACTORS, CARPENTERS, &c., requiring Mortising Machines, previous to purchasing, to examine and test *their patent combined Crank and Lever Machine*, which will Mortise (Tenon and Bore, if required) both Hard and Soft Wood, and is also adapted for Drilling and Punching Iron.

The superiority of this Machine over *all* others consists *in the substitution of a solid wrought-iron plate Crank or Eccentric, by which greater power is obtained, in place of cast-metal Rack and Pinion Wheel, the Teeth or Cogs in which are so liable to strip or break out*—in the direct and perpendicular action of the Lever and Crank on the Cutting Tool, and consequent diminution of friction—in being *stronger* and *less complicated* in its construction, and more *powerful* in its motion—in the *facility* of its *adaptation* to the various depths of material—and in its *non-liability to break* or get out of working order.

This Machine has now been adopted in preference to *all others* by some of the principal Builders in London, Glasgow, Edinburgh, Dublin, and Belfast, who will bear testimony to its being the most powerful and efficient yet made.

For further particulars apply to the Patentees and Makers, GALLON, BEAN, and LUMB, LEEDS.

Extract from the Report of the Royal Dublin Society's Spring Show, 1859:—

"Gallon, Bean, and Lumb, Leeds, exhibited a very useful and complete Mortising Machine, which was highly commended."

N.B.—The Patentees respectfully intimate that this Patent extends to, and comprises Machines for Mortising by Steam and other motive power, as well as by hand: and makers and vendors of, or parties buying or using Mortising Machines, *are cautioned against any infringement*, as the patent right will be strictly maintained.

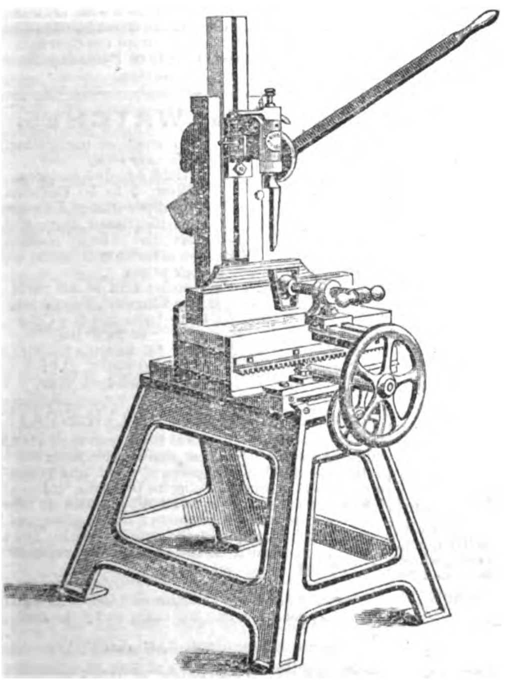
THE PATENT CRYSTAL WINDOW BARS, adapted for Domestic Windows, Shop Fronts, Conservatories, Skylights, Verandahs, Exhibition and Counter Cases, Aquariums, Fern Cases, etc., etc., combining perfect transmission of light, durability against rust or decay, and economy in the facility with which they are kept clean.

Aquariums with Slate or Marble Bottoms of various sizes, with or without Fountains, also of glass.

Manufactured by LLOYD & SUMMERFIELD, Park Glass-Works, Birmingham.

All kinds of Flint Glass, cut and plain, Coloured Window Sheet, Optical Sheet, Coloured Lenses, etc.

Agents at Dublin—Messrs. SIBTHORPE and SON, CORK-HILL.



WILLIAM BISSELL,

UNION-STREET,

WOLVERHAMPTON,

SOLE Proprietor of the Improved MORTISING MACHINE, the newest, most easy, simple, and powerful yet invented.

Also the universally and justly-celebrated Equi-action

RIM AND MORTISE LOCKS.

Patentee of the well-known

FLOORING DOGS,

AND

4-TON LIFTIFG JACKS.

FACTOR

AND

General Manufacturer

OF

BUILDERS' IRONMONGERY.

THE ARCHITECTURAL MUSEUM

SOUTH KENSINGTON MUSEUM, LONDON.

Patron, H. R. H. THE PRINCE CONSORT.

TO ART-STUDENTS AND ARTIST-WORKMEN.

PRIZES are offered for MODELLING, METAL-WORK, WOOD-CARVING, COLOURED DECORATION, and DRAWINGS for PAINTED GLASS.

Particulars may be had at the Office of the DUBLIN BUILDER; of the Attendant in the Gallery of the Architectural Museum; or by letter to the Honorary Secretary, at 13, Stratford-place, W.

A. J. B. BERESFORD HOPE, President.
GEO. GILBERT SCOTT, Treasurer.
JOSEPH CLARKE, Hon. Sec.
(13, Stratford-place, W.)

ART-UNION OF IRELAND.—

President—THE EARL OF CHARLEMONT.

There will be one Prize of £100, and a graduated scale from that downwards, similar to last year, in proportion to the amount of Subscriptions for the year.

ONE GUINEA EACH SHARE.

Prizeholders have the right of selection in all cases. Subscriptions will be received by Members of the Committee; by the Secretary, George F. Mulvany, Esq., 113, Grafton-street; and by the Local Agents in Dublin and throughout Ireland. Copies of the Report of last year and Prospectuses sent free by post.

SUBSCRIPTION LISTS WILL CLOSE ON 25TH INST.

SHILLING ART UNION OF DUBLIN.

ON THE MONEY PRIZE SYSTEM.

SANCTIONED BY THE PRIVY COUNCIL FOR TRADE.

RIGHT of Selection by Prize Holders from the Royal Hibernian Academy's Exhibition. Drawing of Prizes on 1st of June. Highest Prize not to be less than ONE HUNDRED POUNDS.

SHARES ONE SHILLING EACH.

To be had from all Printsellers and Stationers, from Members of the Committee, and from the Society's Agents.—By order, M. ANGELO HAYES, Sec.,
4, SALEM-PLACE.

On receipt of 13 postage stamps a ticket will be forwarded by the Secretary. Letters of inquiry must enclose a stamp.

Machinery, Patents, &c.

IMPROVED APPLICATION OF WATER POWER.

THE TURBINE.

MAC ADAM, BROTHERS, & CO., ENGINEERS, SOHO FOUNDRY, BELFAST, have been engaged for twelve years, with complete success, in manufacturing their improved TURBINES, and can recommend them with confidence. These Wheels are applicable to all practicable heights of fall and quantities of water, giving a much higher per-centage of power than the best VERTICAL WATER WHEELS. On low falls they have the great advantage of not being affected by floods or back-water. Further particulars on application.

HAMMERSMITH IRON WORKS, DUBLIN.

MESSRS. TURNER AND GIBSON,

Manufacturers of IRON CONSERVATORIES, Fruit Houses, Pine Pits, etc.

ORNAMENTAL WORKS, Bowers, Porches, Balustrades, Trellises, Flower Stands, Vases, etc.

GRAND ENTRANCE GATES, Guard Railings, Farm Gates, Hurdles, and Strained Wire Fencing, etc.

IRON ROOFS for Railway Stations, Breweries, Gas Works, and Farm Buildings, etc.

WARMING & VENTILATING Dwelling Houses, Prisons, Conservatories, Mills, and Public Buildings, etc.; House, Laundry, Cooking, and Steaming Apparatus.

BRIDGES, GIRDERS, Iron Lattice, Bowstring, Suspension, Patent Balance Rolling, and Swivel Bridges, and Floor Girders

T. and G. beg to refer, as specimens of *their work*, to the Iron Conservatories, Heating, etc., as erected at the ROYAL BOTANIC GARDENS, KEW; the INNER CIRCLE BOTANIC, REGENT'S PARK; CHELTENHAM; VICEREGAL LODGE; GLASNEVIN; and various Works by them throughout the United Kingdom.

HODGES and SONS' IMPROVED

HOT WATER HEATING APPARATUS.

The most efficient mode of warming HOT-HOUSES, Conservatories, Public Buildings, Churches, Shops, &c. HODGES and SONS request the attention of parties requiring heating apparatus to their improved method, which, by means of the peculiar construction of the Boiler, is capable of raising a very high temperature at an almost nominal cost for fuel; the ordinary refuse of a dwelling-house being sufficient to keep it in full working power.

HODGES AND SONS,
16, WESTMORELAND-STREET, and
20 and 21, ASTON'S-QUAY.

MANUFACTORY — PRICE'S-LANE, ASTON'S-QUAY.

N.B.—Force Pumps, Baths, and all description of Hydraulic Plumbing work executed on the most improved principle.

Building Materials.

SAWING, PLANING, & MOULDING MILLS,

GREAT BRUNSWICK-STREET, DUBLIN,

MICHAEL MEADE,

HAVING completed the extensive Buildings and Machinery for Sawing, Planing, Moulding, Tenoning, Grooving, &c., Timbers at his new works, begs to inform his friends and the public that, in conjunction with his business as Builder, he has opened a new department for the sale of all descriptions of Materials used in Building. Timber, Deals, Laths, Prepared Flooring, Skirtings and Mouldings of all Sizes and Patterns always on hand. Doors, Sashes, Sash Frames, Shutters, Architraves, &c., made to order on the shortest notice and most reasonable terms. Being the *only* Manufactory of the kind in Dublin, it offers an advantage to persons Building which has not hitherto presented itself in this country.

From M. M.'s long practical experience in the working of all descriptions of Timber, persons requiring their Timber sawn or planed will find a great advantage in sending it to the above Mills.

THOMAS HENRY CARROLL,
70, SIR JOHN ROGERSON'S-QUAY,
(formerly occupied by Mr. James Fagan).
Now landing, ex CLIO, from Quebec,
The following FIRST-CLASS TIMBER GOODS:—
Prime Red Pine, of largest average and superior description.
" *Quebec Oak, Elm and Ash.*
" *White Pine*, clean and large.
" *Pine Board Timber*, of largest averages.
" *Pine Deals & Plank*, 1st & 2d quality (no 3rds).
" *Spruce Deals & Battens*, do., do., do.
" *Pine Staves and Hogshead Staves.*

N.B.—This Cargo is one of the best ever brought into this market, and the Timber will be sold according to the established rule of the port—viz., STRING MEASURE.

70, SIR JOHN ROGERSON'S-QUAY.

Is also fully supplied with the best ENGLISH, IRISH, and SCOTCH CLAY GOODS, including

Roof Tile,	all sizes,	Fire Bricks and Blocks,
Paving Tile,	do.	Chimney Tops and Cans.
Ridge Tile,	do.	Common and Fancy Bricks.
Sewer Pipe,	do.	Red Fronting Bricks.

Bangor Slates, and Bangor and Valencia Slate Slabs, Slate Cisterns; Portland, Scotch, Caen, and Daubigny Stone; Irish Limestone, in Block; Yorkshire and other Flagging; Seasoned Mahogany and Walnut Plank.

TWO CARGOES OF FIRE-CLAY *(Coal Island)* DRAINAGE PIPES, are now discharging.

R. H. MONSELL begs to inform his Friends and the Public that he has resigned his appointment with Messrs. JOHN MARTIN and SON, and is now conducting the above establishment. All orders entrusted to his care will have, as usual, his personal attention.

SUPERIOR RED FRONTING BRICKS, also Prime Stock Bricks, delivered at any Station on the Dublin and Wicklow Railway, at Kingstown, Dublin, &c., can be had from

BENTLEY AND SON,
110, GRAFTON-STREET, DUBLIN.

Samples lie at our office.

BUILDERS' GOODS, Kitchen Ranges, Ironmongery, Window Glass, Oils, Paints, and Paper Hangings, of the best qualities, at MAURICE BROOKS', SACKVILLE-PLACE, DUBLIN.

PATENT RIDGE TRESSLE,

FOR Builders, Bricklayers, Painters, &c. These Tressles will be found very important, as they make a safe and useful Scaffold on the Ridge of a Building in a few minutes.

For particulars apply to WILLIAM WILKINS, BUILDER, BANBURY, OXFORDSHIRE.

TIMBER AND SLATE STORES,
SWIFT'S-ROW, LOWER ORMOND-QUAY
(Near the Metal Bridge).

Mahogany, Cedar, Rosewood, Walnut, Birch, American Ash, Pine, Deals, Staves, &c., &c. A large Stock of Staves on hands. Country Orders promptly attended to. GEORGE FINNEGAN.

BATH STONE OF BEST QUALITY.

PICTOR AND SON, QUARRY PROPRIETORS and STONE MERCHANTS, BATH. List of Prices of Box Ground, and Corsham Down Stone (loaded in railway trucks at Box or Corsham Station), also cost of transit to all parts of the kingdom forwarded on application to Bath Freestone Works, Box, near Chippenham, Wilts. Dressings (both plain and ornamental) prepared ready for fixing.) Vases, Tombs, Chimney-pieces, &c.

SCOTCH FREESTONE OF BEST QUALITY.

LEADBETTER, GOVAN, AND CO.,
HUNTERSHILL AND COLTMUIR QUARRIES,
BISHOPSBRIDGE, NEAR GLASGOW.
OFFICE IN GLASGOW—13, GORDON-ST.

STONES furnished, to any extent, in Blocks, Scantlings, or sawn up to any thickness, on the shortest notice, from the above extensive and well-known Quarries

This Stone is now largely used in Ireland for the ashlar fronts of Public Buildings, Noblemen's Mansions, cut stone dressings, interior columns and arches of churches, dressings of schools and villas, and is well adapted for every purpose to which cut stone is applied.

The facilities for shipping are unsurpassed, being connected by private railway with the Forth and Clyde Canal (within a few miles of the Clyde), where vessels of upwards of a hundred tons can be loaded in a few hours.

L., G., and Co., will be happy to furnish Architects, Builders, and others with list of prices at the Quarries, free on board, and freight to any port in the kingdom.

All orders promptly and carefully shipped.

OFFICE OF THE "CROWHILL, MILTON, AND KENMUIR QUARRY COMPANY (Limited)."

51, RENFIELD-STREET, GLASGOW.

HAVING entered upon a Lease of those extensive and well-known Quarries—Crowhill, Milton, and Kenmuir, near Bishopbriggs—long wrought by Mr. Wm. Neilson, parties desirous of supplying themselves with a first-class Rock, will be served promptly with any quantity, however large.

From our facilities for despatching materials by private Railway to Forth and Clyde Canal, Builders in Ireland will find this a cheap and ready mode of supplying themselves.

Any orders with which we may be favoured, shall receive our best attention.

WILLIAM GRAY, Secretary.

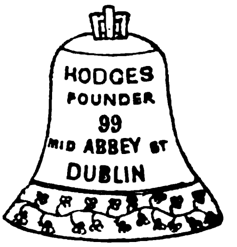
NOTE—We refer for sample of our stone to the new National Practising Schools, at Lower Gardiner-street, Dublin, and new Exchange, Dundalk.

BATH STONE OF BEST QUALITY.

RANDELL AND SAUNDERS,
QUARRYMEN and STONE-MERCHANTS,
BATH.

List of prices at the Quarries and Depots, also cost of transit to any part of the United Kingdom, furnished on application to Bath Stone Office, Corsham, Wilts.

London and Paris Great Exhibitions



Prize Medal Bells.

PATENT ASPHALTE ROOFING FELT.

ELLIS AND CO.,
MALONE MILLS, BELFAST,
Manufacturers of
PATENT ASPHALTE ROOFING, SHEETING, INODOROUS, AND BOILER FELTS.
Sole Agents in Dublin,
Messrs. CAROLIN AND EGAN, 20, EDEN-QUAY

ASPHALTIC ROOFING FELT, a light, clean, economical, and durable roofing, price 1d. per square foot. Samples and instructions may be had gratis in answer to letters from any part addressed to MAURICE BROOKS, IRONMONGERY, GLASS, & ROOM PAPER WAREHOUSE, SACKVILLE-PLACE.

DRAUGHTS of COLD AIR round DOORS and WINDOWS prevented by GREENWOOD'S PATENT INDIA RUBBER STOPS, and Self-acting Slides, for the bottoms of Doors, which have proved to supersede all previous invention for the purpose of Making the Joints of Doors, Windows, Show Cases, &c., AIR TIGHT.

Agents for the Patentee—
FERGUSON AND CO.,
Patentees & Manufacturers of Vulcanized India Rubber, Gutta Percha Waterproof & Airproof Fabrics,
105, GRAFTON-ST., DUBLIN.

Building Ground, &c.

BUILDING GROUND at RATHGAR—between Kenilworth-square and Harold's-cross-road, near Roundtown—to be Let, at from 2s. to 3s. per Foot, Landed Estates Court Title, and 900 years' Lease. Apply to

BENTLEY AND SON,
110, GRAFTON-STREET, DUBLIN.

N.B.—A Quarry on the land, and bricks at half-price.

A FEW HALF-ACRE PLOTS at DUNDRUM for Detached Houses, within three minutes' walk of the Railway Station, to be Let cheap. Bricks and Stone on very moderate terms to parties building.

BENTLEY AND SON,
110, GRAFTON-STREET, DUBLIN.

BELMYRA, DUNDRUM, CO. DUBLIN.
TO CAPITALISTS, BUILDERS, & OTHERS.

MOST DESIRABLE BUILDING GROUND TO BE LET.—This Estate, containing 150 Acres, situated within half a mile of the Dundrum Railway Station, has been laid out in Lots for Building. The position is admitted to be the most beautiful in the environs of Dublin, and is particularly well circumstanced in every respect, commanding views of Killiney Hill, overlooking Mount Merrion, City and Bay of Dublin, &c.

A railway station in the centre of the estate is in contemplation, bringing it within ten minutes' drive per rail of Harcourt-street.

A map of the lands, showing them laid out in building lots, can be seen, and every information obtained, at the offices of Edward Henry Carson, C.E., Architect, &c., 25, Harcourt-street.

TO BUILDERS.—TO BE LET, in RATHGAR, on the Roundtown-road, about 500 Feet of BUILDING GROUND, 260 feet from front to rere, at 4s. per foot. Also, in Rathgar-avenue and Beauchamp-avenue, 2,000 feet, at 3s. per foot. Lease 999 years. The situation is unquestionably the best in the suburbs of Dublin. Apply to Dr. BEAUCHAMP, 115, BAGGOT-STREET; or to F. ARMSTRONG, Builder, BAGGOT-STREET.

NEWBRIDGE—BUILDING GROUND. Several Lots of BUILDING GROUND to be LET in the rising and rapidly improving town of NEWBRIDGE, in the County of Kildare, including a most eligible site reserved for an Hotel, which is very much required in the neighbourhood, and which would be sure to have immense business, there being nothing of the kind capable of meeting the requirements of the large Cavalry Garrison at Newbridge, the Camp on the Curragh, and the crowds who come in summer for the reviews and races on that grand plain.

Newbridge is a most central position for the meets of the Kildare Hounds (being itself one of them), and is close to the Station on the Great Southern and Western Railway, and one mile from the Curragh.

For further Particulars apply to Ponsonby Moore, Esq., Moorefield House, Newbridge.

BENSON'S WATCHES.

"Perfection of mechanism."
—*Morning Post.*
Gold, 5 to 100 Guineas.
Silver, 2 to 50 Guineas.
Send two stamps for "Benson's Illustrated Pamphlet," descriptive of every construction of watch now made, with their prices.
Watches sent to all parts of the Kingdom, free by post.
Or to India and the Colonies for 5s. extra.
33 & 34, LUDGATE HILL, LONDON, E.C.
Established 1749.

IBBOTSON'S IMPROVED OAK STAIN, for imparting to New Deal the appearance of Oak, and to New Oak the appearance of Antiquity.

It is about half the expense of paint, and is easily applied with a brush. Being an Oil Stain, it has the important advantage over all other stains of being impervious to wet. It produces a bright gloss, but if a high polish is required, the proper varnish can be applied. It requires no size or previous preparation of the wood.

The Stain (with the proper varnish, if required), of three shades—Light, Middle, and Dark—is sold in Bottles at 6d., 1s., and 2s. each, or by the Gallon, at 10s.

SOLE AGENTS—BOILEAU AND BOYD,
(Late John George Boileau and Co., Mary's-abbey)
92, BRIDE-STREET, DUBLIN.

The Dublin Builder.

VOL. II.—No. 18.

ART EXHIBITION—ROYAL HIBERNIAN ACADEMY.

THOUGH, numerically speaking, the display at the present exhibition—the thirty-second—of the Academy is not equal to many of its predecessors, in excellence it is nevertheless superior to the majority, and certainly inferior to none of those that we can call to mind. Exercising a wise discretion, and in direct contradiction to the principle that heretofore induced the Council to cover every available inch of wall-space with any sort of production that might be denominated "a picture," by way of "not discouraging young artists," the present Committee boldly decided on rejecting every contribution that had not *some* claim to merit—and numbers were deemed unworthy—hence the comparative paucity of works this year. We wish, however, that the same principle had been extended to the architectural department, which is contemptibly meagre; and 'twere better far that the triplet sister's name had not been associated at all with painting and sculpture, but were expunged from the catalogue altogether. On previous occasions we alluded to the unpardonable apathy of the architectural profession towards contributing works to these periodical exhibitions of—what should be regarded by its members—a "national" art institution; but never, to our knowledge, has it been so glaringly palpable as this year. Whence the cause? Lack of ability there is none; the general excellence of the designs even furnished in the recent competitions—for the Molyneux and St. Andrew's Churches—incontestibly evidence *that fact*. *Apropos* to this, and cautiously touching on personalities, may we collectively ask the authors of the designs in question, might they not have perpetuated their own merits in the public eye, and conferred an essential benefit on this department of the Academy, by sending them to this exhibition? We learn that such was the intention of *one* of the competitors, the fulfilment of which, however, seems to have been prevented by some unexplained cause; but it would have pleased us to hear that even the *intention* were more general. The first responsibility of aiding an institution in its purpose devolves on its own members' example, and, if contributions be thence found wanting, the fault is trebly culpable; so we must remark, that of those now identified with the Academy, we find but one architect exhibitor—viz., Mr. M'Carthy, who contributes a view of Saint John's new Church, Convent, and Schools at Tralee; but, judging from that gentleman's extensive practice, we should have looked for a more important display; however, the drawing stands out in bold relief from the two or three others—shall we say architectural?—with which it is placed in juxta-position. That in our future reviews opportunity may not be afforded for similar strictures on the profession is our sincere wish, both for the credit of its members, the sake of art, and the welfare of the Academy; and in this spirit are our remarks dictated. Intended changes in the constitution of this body, by which an additional number of architects will be admissible as members or associates, will doubtless effect a desired end in this respect; and let us hope that the elected gentlemen—whoever they may be—will, by their practical encouragement and example, prove themselves worthy of their position.

Among the foreign pictures, the contributions of Otto de Thoren, of Brussels, author of "Managing" (No. 17), and "The Steeple Chase" (No. 168), are distinguished for their solid and effective manner; his paintings of horses are not surpassed by the best of our English artists.

Eugene de Block, another of the Belgian school. produces works in a very vigorous style, full of character, and powerful in colour. He contributes "French Taught Here" (No. 173), a somewhat unintelligible title at first view, but evidently a libel on *how* it *is* taught, as the scholars are all represented at the *wrong* side of the school-house door, and in uproarious confusion; while the amazed master, invested with his badge of authority, sallies forth to allay the tumult; No. 209, "The First Lesson," and 234, "The Prayer at the Grave."

Camille Venneman, of Antwerp, paints very much in the manner of the old Flemish masters, deep in colour and admirable in character and expression. His "Laitures dans la Prairie" (No. 68), and his "Fete de Village" (459), are full of freedom and beauty.

Jules Wagner has two exquisite pictures—probably the most attractive in the large room—"Musique, Femme, et Vin" (No. 38), and "La Châteleine" (No. 50). Deventer, of Amsterdam, has two "Sea Views," and "A Landscape" of merit. Pierre Dielman displays great excellence in "L'Ane et Moutons" (No 24). Versheur's (No. 128) "Horses" deserve special mention. P. V. Schendel, who, if we mistake not, was the artist of "The Adoration of the Majii," displayed at a previous exhibition, has another this year, wherein the effect of lamplight on a lady playing the guitar is marvellously wonderful (see No. 415).

Of the English school we do not find an example this season of extraordinary merit, but there are several possessing considerable excellence. The painting of "the Irish Council," bought by her Majesty, cannot be deemed one of Wilkie's best works, at least as a specimen of colouring: yet in composition, character, and general arrangement, it is clever. It would also appear as if the picture had been somewhat tampered with, by a cleansing process probably.

The cattle pieces of Willis and Cooper are admirable; Armitage, Duncan, and Fisher—our Irish artist, long resident in London—are well represented in their general styles.

In water colour, Harding, Miss Macerone, and a few others, are of the English schools. Our native artists, in the number and merit of their works, contributed by far the most attractive portion of the exhibition; in several departments—in landscape particularly—they may now be said to fear no competition. The representations of our romantic scenery are rendered with a gratifying fidelity, and a great amount of artistic skill. And we should specially make honourable allusion to those by M. Kendrick, R.H.A.; Edwin Hayes, Bradford, Patrick Vincent Duffy, A. Nicholl, T. S. Cooper, A.R.A.; William Craig, J. Richard Marquis, &c., &c., without disparagement to the works of many other artists too numerous in a necessarily circumscribed notice even to allude to.

There are comparatively few figure subjects, but nevertheless some of much merit are exhibited, including Scriptural and other historical and domestic scenes. They afford evidence of a fine feeling for the higher departments in art, and we hope to see an increased demand for works of this class, calculated to inspire an artist with a noble ambition in his profession.

Of portraiture there is less than in any former exhibition. Mrs. Smith's portraits in oil, Mr. Mulrenin's minatures, and Mr. Jones' water colour, are the principal productions in this line. There is an admirable water colour drawing by Burton, of which no words can convey an adequate idea.

Amongst the sculptural works—which we must also remark, *en passant*, are neither as numerous nor as excellent as on previous occasions—Messrs. Thomas Farrell and Joseph Kirk exhibit models of their respective designs for the bas reliefs on the Wellington testimonial pedestal, already described in this journal; as also do Messrs. Terence Farrell for General Cole's statue, to be erected at Enniskillen; Mr. William Farrell a Madonna, Mr. James Farrell a Statuette of Goldsmith, Mr. John Farrell a Sleeping Youth, in marble; in all, serving to sustain the reputation of that eminent firm. Mr. Halse, an English sculptor, has also some figures in marble and plaster, which deserve attention. A bust from the chisel of the late John Hogan attracts much notice, and suggests the oft-repeated exclamation, "Poor Hogan."

The prizeholders in the Art Union of Ireland seem to have already selected various works, and their selections are generally judicious; after the drawing of the Shilling Art Union we doubtless shall notice many others labelled.

COMPETITIVE EXAMINATION.—The Directors of the Waterford and Limerick Railway requiring two junior clerks at the Waterford station, caused all the candidates—fifteen in number—to be examined in writing, dictation, grammar, arithmetic, geography, and history, by the Master of the Clonmel model school, and selected two who had been respectively educated in the Christian Brothers and the model schools in Waterford.

THE USES AND ABUSES OF IRON IN CONSTRUCTION.

By the following remarks we must not be considered as deteriorating a material that the experience of late years has proved of such advantage, both in an architectural and engineering sense; but we wish to point out one or two growing evils, traceable to what may be termed a too eager adaptation. It is a subject demanding larger space, but we must content ourselves with a few brief remarks.

As a nation we are slow, even to a fault, to adopt a newly-discovered article, and treat it often with undeserved suspicion. With iron we were remarkably cautious, but in all forms it has become of such universal use, as facilities for producing it have increased, that to raise a doubt upon its applicability to almost every purpose, would seem to partake of the retrograde. And here we must remind our readers that it is not the material that we would find fault with at all, but the frequent recklessness displayed in dealing with it.

In the first place we allude to shop-fronts, now generally supported on slender cast-iron columns, girders passing along upon the caps, and thus supporting a heavy pile of brick-work. The columns in some instances are weak enough, and their distances apart somewhat alarming to behold. Now, presuming that these, with their superincumbent girders, are strong enough to bear the brick-work or stone-work above—do they look so? Their appearance is calculated to raise a doubt in the mind of the passer-by, as to their stability, and is this consistent with the spirit of architectural effect? We should say not. It remains to be seen in a few years, when settlement shall have taken place, when sand or water may have caused what is called a "drain" upon the footings, whether these columns will remain plumb, and the consequences that would ensue on such an event as their not doing so. We hope they may prove equal to their task. Not heeding eventualities, we may presume a section just sufficient to support the weight above, let one flaw exist in that section, and the safety of the whole building is jeopardised. There are sufficient reasons why those who are so desirous of gaining window-space should be careful not to risk a complete building to the saving of a little more iron in columns on which so much depends. So much more imperative is it that their sectional area should be in many instances increased, not on account of vertical pressure, but, if need be (which is very likely), to resist in some measure a lateral thrust.

In the second place, to make a great stride from domestic architecture to marine, there seems a grave doubt to exist whether we shall not eventually step over the bounds of prudence, and by using iron to an excess, forget that good old seasoned oak has ever weathered the storm in days of yore. The uncertainty of iron in the storm, as proved in the case of the "Royal Charter" and others, owing to its brittle nature, and if it fails at all, in the completeness and suddenness of the catastrophe, must go far to enforce caution on those who are now using it to so great an extent. Highly questionable is it whether it will really last so long as the stout timber; some, nay many, think not, but for the furtherance of sailing properties, we cannot doubt its exclusive advantages. Great improvements will render it more valuable. Cast steel, being of course another preparation of iron, now used so largely for railway purposes, will, ere long, take its proper place, and no doubt will answer, though it cannot in all the modes anticipated by its too sanguine admirers. All we have to guard against is excess, and in engineering or architectural science moderation may be considered a virtue, as in other things. We do not depreciate enterprise when it is conducted in a legitimate and scientific manner, but it is often but a foolish venture, and the strength of material has sometimes very little consideration.

Extensive alterations and improvements are being made at Bride's Church, in this city, under the directions of the Ecclesiastical Commissioners' Architects, and partly comprise new windows, sashes, &c., a pulpit, reader's desk, pewing, &c. Messrs. Barker, of Upper Abbey-street, are the builders.

Twenty-nine houses are proposed to be built simultaneously at Bray. Mr. O'Kelly, architect.

A new Protestant Cemetery is to be formed at Waterford; the Lord Bishop of Cashel gives £100 subscription towards the purchase of the ground.

A new Convent, dedicated to "Our Lady of Mercy," is to be built in the town of Newry. Mr. John Bourke, Architect.

The Armagh District Lunatic Asylum is to be altered, under the direction of Mr. J. Boyd, Architect, Belfast.

The new Catholic church of Killinagh, near Ross, is being proceeded with, and the walls are advancing to completion.

A new National Schoolhouse is to be built at Ballycorus, near Golden Ball, by the Board of Public Works. [For Particulars as to Tenders refer to our Advertisement pages.]

A new Roman Catholic church is to be built at Collon, county Louth; the skeleton and the roofing will be proceeded with on separate contract. Mr. Murray, architect. Tenders to 2nd instant.

THE NEW AUGUSTINIAN CHURCH, JOHN-STREET.

In Notices of the Architectural Designs at the Royal Academy Exhibition by our London contemporaries we find the following, which have taken us somewhat by surprise, as we had authority for believing that the building in question would have been left open for competition by the profession.

"The view of 'St. Augustine's Church, Dublin' (657), exhibited by Mr. E. W. Pugin, represents a design by Messrs. Pugin and Ashlin. The building is, we suppose, one lately erected; but, by one of those omissions which we have frequently to mention, the catalogue does not inform us on the point. The whole western end of the church for the space of one bay of the aisles, rises to the height of the clerestory, so as to form a transept on the western extremity of the plan; whilst the tower rises still higher, and is oblong on plan—being carried upon one bay of the nave. The roofs of the transepts are hipped at the ends, and the tower is crowned by a high-pitched roof, on a similar plan. There are three doorways, and windows over them, the centre being made prominent by a lofty arch, the window under it circular. The whole west end, as shown, has considerable novelty and merit."

657. "This is another fine Roman Catholic church, 'St. Augustine's, Dublin,' by Mr. E. W. Pugin. The tower is raised over one bay of the nave, and is thus broader from north to south than from west to east. The roofs of the corresponding bays of aisles are carried a little higher than the others, and abut against the tower, which gives a very agreeable outline to the building. The details are worked out with Mr. Pugin's well-known skill. The only objection we have to make is the same which we noticed in his drawings in the Architectural Exhibition, that it is rather overloaded with ornament and the features too crowded together."

Organ Building.—Messrs. Telford, of Stephen's-green, have erected a powerful instrument, combining great organ, 56 notes; choir organ, do.; swell organ, 44 do.; pedal organ, with grand double diapason, 16 feet pipes; three composition pedals, coupling action, swells, 82 stops, and 1610 pipes, in the new church of St. Catherine, Meath-street. It is in a gallery at the west end of the church, and the case placed at either side of the great window so as not to interfere therewith.

A new and powerful organ has been erected in the Roman Catholic Church of St. Paul, Arran-quay, by Messrs. John White & Son, of Bishop-street. It is said "to reflect the highest credit on native labour." The design is Grecian, to correspond with the style of the church. There are 42 stops and 1968 pipes.

Two lime-kilns, built by order of the Marquess of Conyngham, are now at full work outside Kilkee, and the Messrs M'Donnell, of Kilrush, have introduced brick burning at Fougha, which affords great facility for building. The Messrs. M'Donnell have erected a hotel at the west side of Kilkee, of brick material.

The telegraph cable of 1,200 miles, to be laid between Rangoon and Singapore is being tested by Mr. W. Reid's process, which consists in placing a coil of gutta percha in an air-tight cylinder, which when exhausted, a column of water is allowed to rush in, filling up the holes and crevices; and in this state tested by a delicate galvanometer. A pressure equal to that it must bear in the bed of the ocean, is then applied, and if there be any defect in the insulating medium, its detection is inevitable. The cost of testing is less than £5 per cent. on the cost of the cable.

The Great Prize Drawings.—Despite the Government warning, the "Limerick Athenæum and School of Art" and the "New Catholic Church of Carrickmacross" prize drawings *will* be proceeded with. In the former case there will be a prize of £300, of £200, of £100, of £50, of £40, two of £25, three of £20, and twenty of £10 each; and in the latter thirty-one, ranging from £1,000 to £10. We have already expressed ourselves on the principle of this system as regards "religious structures."

The Catholic Young Men's Society.—We perceive that there has been a Concert in aid of the Funds of this Society, and said to have resulted satisfactorily. The Committee have published a complimentary statement "in grateful acknowledgment of Miss Julia Cruise's gratuitous services," and of the earnestness and vigour which characterised her performance on the occasion, evidencing her benevolent disposition, and adding another proof—if needed—of those splendid gifts she possesses, and which must always insure success for any undertaking of the kind she may assist in. The obligations of the Society to the other artistes, Mrs. Cantwell, Mrs. Mahon, Mrs. Manley, Mr. Halton, and Mr. Reane were also recorded. This Institution presents many advantages to those for whom it was established, and is exclusively Catholic in its tendencies.

New Lunatic Asylum for Donegal.—It is proposed to build a separate Lunatic Asylum for this county. As yet we believe it has not been determined whether the site will be at Letterkenny or Lifford.

SAINT ANDREW'S NEW CHURCH.

The Paternity of the Designs.

RELEASED from the two distinct ties that bound us in giving our last report to preserve the incognito of the competitors—the one, justice to the authors, that *each* might equally enjoy his opportunity of asserting a claim to the palm; the other, that the committee of selection should be unprejudiced in their decision by a parade of names, some bearing the *prestige* of favourable professional antecedents, while others were less fortunate—we resume the subject, disregarding the *noms de plume* and divulging the authorship. We must, however, remark, that the obligation above alluded to was self imposed from a sense of good taste, which we notice with much regret is not invariably observed by brother journalists with similar mission to ours; and from the various communications—unexceptionally complimentary to the impartiality of our review—we are induced to hope that it has been appreciated. We abstain from referring in this personal notice to the authors of those designs whose display did not come exactly within the circle of our approbation, in the sincere desire that our pen—while guided by an independent hand, and a spirit scorning undue respect of persons, at the same time bent on awarding merit to those who deserve it—may never *intentionally* communicate offensive expressions to any.

Following the same course as before, but merely *glancing* at "Finem respice," we come to the design marked "Fides," by Mr. Slater, respecting which, having already expressed our opinion rather fully, we will not further notice. Passing thence to No. 4 on our list, "Resurgam," we may correct a very general misapprehension by stating, that the author was Mr. William Atkins, of Cork, although attributed to Mr. Brandon, and although that gentleman's (Atkins) name was erroneously identified with another "Resurgam," placed between monogram "Shamrock in a circle" and "Excelsior," in a corresponding angle of the octagonal apartment, and which now we learn was by Mr. Drew, a young architect evidently of ability. To Mr. Drew's merit be it stated, that he wrote to us from Naas, specially informing us of the error, and modestly alleging "that a gentleman of Mr. Atkins's known taste and experience, would scarcely feel flattered at having the design of a very young and comparatively inexperienced architect attributed to him." Mr. Bell, pupil of Lanyon and Lynn, and recently connected with the architectural department, Board of Public Works, was represented by monogram "T in a circle." Again—only *glancing* at *the* "Resurgam" in pity more than anger—we pass to "Delta," by Mr. Semple, architect, who somewhat closely, but much less successfully, perpetuates the same style as that adopted in the Black Church, Mountjoy-street, and in Rathmines Church. Mr. Rawson Carroll, the successful candidate in two recent important competitions—viz., the new Commercial Mart in Grafton-street, now completed, and the Molyneux Church and Asylum at Leeson Park, as illustrated in April number of the DUBLIN BUILDER, adopted as his motto "In fide et in bello fortis," and, as already stated, his designs—two in number—were most creditable; one, the cheaper of the two, somewhat preferable to the other. In the next compartment, Mr. Raffles Brown, with uncoloured, but beautifully handled elevations, and half-finished plans and sections—the set distinguished by "Templa quam delecta"—nevertheless shone refulgent in excellence, and we hazard no censure in advancing that the competitors themselves united in that admission. The financial question relative to this and others, we, of course, for the present leave to the committee to exercise their discretion upon. We must observe, that Mr. Brown was not associated with any other professional in the competition. Probably we assume erroneously in surmising the absence of Mr. Woodward's assistance in the design, "Donec templa refeceris," by Messrs. Deane and Woodward, without disparagement, however, of the capabilities of the gentlemen connected with that firm, and which are of no minor order. Frankly, however, there *was* a feeling of disappointment, probably arising from the invariable expectancy that first-rate artists must never be below the mark, even to a line. The geometrical drawings were, nevertheless, executed by a neat and skilful hand—probably somewhat too rigid; but the external perspective, though a masterpiece of colouring in its style, failed to make the intended favourable impression. The authors of monogram "Shamrock in a circle"—Messrs. Lanyon and Lynn, of Belfast—may justly be proud of the head that conceived, and the hands that manipulated, the exquisite treatment of this most excellent study; and though in the result labour may be partially unrequited, nevertheless it is a something to feel that it has been regarded with intense interest and admiration, as well by the public as the professional competitors. As already stated, there was not a second opinion as to this being A 1; but the committee finding that the amount requisite to carry out the work in its integrity, was considerably in excess of their available funds, and the amount stipulated in the instructions, applied to the firm for an amended design, which was accordingly furnished. This design is substantially similar to the original in its main constructive features, but considerably divested of ornamentation, flying buttresses, crocketed pinnacles, elaborate tracery, &c., and of course the imaginary appendages introduced by architect's license in the previous drawings. The *toute ensemble*, however, is most pleasing, and ably treated. We learn that it is accompanied by an estimate from a Belfast builder, that the work provided for can be executed within the stipulated amount. Next to these are Mr. Drew's designs, under the motto "Resurgam," previously referred to, and though under the disadvantage of being placed in juxta-position with the brilliant star next it, the smaller planet, nevertheless, shines prominently in the hemisphere of talent. Belfast is again in the ascendant—at least *adoptedly* so—in the drawings of "Excelsior," by Mr. Thomas Turner, which elicited—and deservedly—general admiration. Mr. John M'Curdy, of this city, was the author of the designs marked "Dum spiro spero"—the last on our list—next the entrance doorway, and evidently incurred much trouble and expense in their preparation. The order of merit in which the committee have placed the six designs selected for final consideration, is—

Lanyon & Lynn (conditional)	1st.	Deane & Woodward	4th.
Ditto	2nd.	Thomas Turner	5th.
Raffles Brown	3rd.	Rawson Carroll	6th.

We presume that the next step of the committee will be to seek for tenders according to the amended plan, and probably we may have more to say by-and-by.

QUANTITY AND QUALITY OF WATER IN BELFAST.

FROM a report, dated October, 1855, by the Water Commissioners of Belfast, as to the supply with water at that period, we quote the following :—

That "The inadequate supply of water in Belfast has been for many years a matter of great and *increasing anxiety* to the Water Commission. The supply from streams and springs to the old and new reservoirs amounts to about five gallons a day for each inhabitant—only one-fourth of the quantity which is estimated as a sufficient supply. And it is not only insufficient, but precarious. *During dry weather* it has several times been near failing altogether. The present scarcity is such that the Commissioners have lately found themselves unwillingly compelled to refuse supplies of water to steam-boats, and they fear they shall be obliged to withdraw all special supplies whatever, that is to say, supplies to steam-engines, factories, soap boilers', butchers', and bakers' establishments, stable-yards, public institutions, and every kind of tenement, except dwelling-houses. And *there is no possibility of obtaining* an increased supply from the present sources, in consequence of the great value which every stream in the immediate neighbourhood of Belfast has acqired for steam and manufacturing purposes.

"In this emergency—the supply being always insufficient and often in danger of failing—the Commissioners have for some time past been compelled, though reluctantly, to increase it by pumping in part from the Lagan. *This water is filthy and impure*, and it has also the disadvantage of costing £1,600 a year for pumping. So *polluted a source* of supply is of course to be regarded as only a temporary expedient to meet a pressing necessity."

Such was the testimony borne by the Water Commissioners themselves. But if the water be bad in quality, or, to use their own words, FILTHY AND IMPURE, and only one-fourth in quantity of what it ought to be, the payment demanded by the Commissioners ought to be small in proportion The reverse, however, is the case, as may be seen by reference to another portion of this journal, where the taxation of the town is treated of.

The Commissioners say, in the manifesto from which we have already quoted :

"Nothing promotes the prosperity of a town more than an abundant supply of pure water, which is essential to almost all manufacturers and to the use of steam-engines. Another very important advantage of an abundant supply of water will be the easier extinction of fires."

With these statements we heartily agree. Property to the extent of £80,000 has been consumed by fires in Belfast during the past ten months, and the loss to insurance companies has been £70,000; yet, the Belfast Water Commissioners met after the great fire in Victoria-street, which consumed the Victoria Chambers, and passed a vote, declaring the supply ample, and that no blame was to be attached to them. It would seem that this method of setting themselves right with the public was of little avail, as the following appears in the *Daily Mercury* of 16th May :

"The Water Board, we must say, has of late been doing all in its power to disgust the town with its separate existence as an independent corporation, and consequently the feeling is now general that it ought to be abolished, and its trusts transferred to the Town Council."

We regret to say, in addition, that the Town Council have not earned many laurels for the wisdom and economy with which they have managed their own affairs for the past ten years of their existence. But as the rod of correction has been applied to them with no unsparing hand, in the shape of a suit in Chancery, which has now lasted five years, perhaps we might anticipate better conduct for the future.

All that the Belfast Water Commissioners have hitherto done they have done unwisely. They made an agreement to pay the Charitable Society £800 per annum for ever for some dirty water and rotten wooden pipes, the water lying below the level of the kitchen floors of many houses in the town, and cannot be delivered 5 feet above the level of any street. They had also undertaken to pay the Marquis of Donegal £550 per annum for what they now contend that his lordship cannot give them, and for which they are consequently unwilling to pay. But we believe a decision of the courts has been made against the Commissioners, and the unfortunate inhabitants will have to pay not only that, but a neat little sum in the shape of law costs.

What, then, can be done that our towns may be delivered from the incubus of these mal-governing bodies, so as to attain a position in which they may be enabled to supply themselves at a moderate expense, with that indispensable necessary of life, pure water? Elsewhere in this journal, on the subject of "rain-water as an auxiliary," we have shown that a catchment basin, one square mile in extent, or 640 acres, at a sufficient elevation, would supply 25,000 persons with an adequate quantity of water all the year round, if economized and equallized in a reservoir, and also that most towns have mountains in their vicinity of sufficient extent and elevation to yield more than can ever be required for the supply. Providence has bountifully supplied our country with many blessings; amongst them, with water in abundance. Then why should it be dealt out to us by Water Commissioners with such niggardliness? The proverb says that "what is everybody's business is nobody's business," and in truth, all neglect their own individual interests, whilst a few ambitious persons put themselves forward as commissioners for supplying a town with water, and succeed only in preventing the effectual accomplishment of that desirable object, whilst they inevitably fall into the hands of some cunning attorney who turns them and their projects into money-making transactions for himself. Being in 9 cases out of 10, men of business—grocers, manufacturers, booksellers, auditors, and merchants, anxiously desirous to make money by their calling, whatever it may be—they cannot be expected to devote the necessary share of attention to the affairs of the trust which it would require, whilst, at the same time, none of their antecedents would lead us to suppose that either nature or education had fitted them for properly discharging the duties of a water commissioner.

Then, another evil exists. The staff absorbs a large amount of the annual income. Clerks, collectors, engineers, inspectors, turncocks, gatekeepers, &c., all must be well paid.

Again, the question arises, what is the remedy? Unfortunately we cannot turn to any unpolluted source. If we say it would be better to have the water supply of a large town managed by one paid commissioner who would devote himself wholly to the matter, and be appointed by the Lord Lieutenant, and made responsible for the proper discharge of his duties, we might be told, perhaps correctly, that it would be merely making so many situations for the adherents of the government of the day. We would doubt the expediency of this arrangement. One thing, however, is palpable, viz., that the inhabitants of towns should lay aside their contentions and unite for the common good, selecting a better class of men for public offices. It is high time that we had a little more economy in the expenditure of public money, both in the state and corporations, as well as in the construction of our wooden walls. Our boasted liberty seems little better than a snare to us, enabling the few to govern and tax us for their own especial profit and advantage.

A NEW CEMENT.—Professor Edmund Davy lately read a paper before the Royal Dublin Society relative to a cement which he obtains by melting together in an iron vessel two parts by weight of common pitch with one part of gutta percha. It forms a homogeneous fluid, which is much more manageable for many useful purposes than gutta percha alone, and which, after being poured into cold water, may be easily wiped dry, and kept for use. The cement adheres with the greatest tenacity to wood, stone, glass, porcelain, ivory, leather, parchment, paper, hair, feathers, silk, woollen, cotton, &c.

A WONDERFUL OPERATION.—The *Chicago Press and Tribune* describes the raising, by means of screws, of a solid front of first-class business blocks, three hundred and twenty feet in length. The block comprises thirteen first-class stores, and a large double marble structure—the Marine Bank buildings—all presenting an unbroken front, and filled with occupants. The block had been raised four feet eight inches in five days, and the masons were busy putting in permanent supports. The entire weight raised was about 35,000 tons, and so carefully had this been done that not a pane of glass was broken, and the internal order of the block had remained undisturbed. Six thousand screws, and about six hundred men, had been employed in the process. The paper adds, that the work as it then stood was worth a walk of miles to see, and had been the marvel and wonder of the inhabitants since it had commenced.

OUR PUBLIC MONUMENTS AND FOUNTAINS.

EVERYBODY seeks novelty, with an appetite that seems to grow by what it feeds upon; and as, physically speaking, human nature continually requires sustenance, which to be palatable must be novel, so, mentally, novelty is the very charm of our existence. By novelty invention thrives; and, though the practical man invokes the spirit of routine, he thrives by that of invention, and without it his enterprise will not avail. If we can, then, by suggestion aid in the glorious work of invention, reproduction, and adaptation, we consider that we fulfil an important part of our duty as journalists and dotters down of universal progress in the arts and sciences as applied to the useful and ornamental.

> "A chiel's amang ye taking notes,
> An' faith he'll prent 'em" ——.

When we contemplate the many examples of architectural and engineering talent by which we are surrounded, we cannot but be somewhat surprised that there are works of art—and those the most conspicuous—neglected or forgotten amidst the mass of detail. To enter an architect's office, and find him surrounded by building acts, bye-laws, quantities, &c., and trammelled by some clients who have formed strange notions of architectural beauty, and the value of professional time, we must not wonder that he should pay little attention (amidst such a fever of competition) to those generalities—viz., public improvements, wherein so many party interests are involved, to meddle with what is sometimes dangerous to his pecuniary welfare.

Public men are those, then, who should concern themselves about public matters; but, if these matters be not political or municipal, how seldom do they? In matters architectural, which history records as having been the most important among great nations of antiquity, they are provokingly silent; they heed not the editorial pen, and the truest records of a nation's greatness are often forgotten or neglected. However, the spirit of improvement is ever on the wing, and touches with his wand some patron of his country's genius.

Since the fountain movement was inaugurated by a private individual there have been great strides in that beneficial direction. In every city or town of importance in the three kingdoms they have been erected, some ornamental and some otherwise, by public and private funds. Designs are plentiful, many of them elegant; but we venture to remark, that they have not yet taken that important position which they deserve. To make them, at the same time, ornamental, suggestive, and monumental, should be our study; and hitherto our monumental system, with a few exceptions, has been painfully *outré*. In the public squares of our great cities, in our parks and gardens, to combine the mementoes of departed greatness with the emblems of life and health would be a combination much to be desired, and, when effected, much to be admired. To complain that the great poets, painters, historians, and philosophers find scarce a place among our public monuments, when monarchs of doubtful wisdom or morality, and warriors (we do not grudge the latter one tittle of their well-earned fame), find so many—to complain of this will seem perhaps carping and puerile; for "of what use is the marble, the cold emblem of a life neglected, after years of toil unrewarded?" But we may ask for a tardy acknowledgment of their great genius, their benefits conferred upon this and succeeding generations, by raising their effigies upon pedestals, from which water may gush forth, and surrounded by plants and shrubs, the whole presenting an opportunity for grouping superior to anything yet afforded, and displaying taste and veneration, two qualities of lasting excellence—for truly "a thing of beauty is a joy for ever."

This would we do; and now how to do it. A central pedestal, placed within a square or circular basin (surrounding a bed of plants or shrubs), the walls of which would form, as it were, a base to the whole. From the sides of the pedestal the water may flow in jets into the basin, which could thus return the water by pipes and filters. Piers may be formed in the walls of basin to carry ornamental lamps, which, filled with crimson or amber-coloured glass, would display the whole as clearly by night as by day. Besides being ornamental, central basins are ever useful in large towns and cities, affording ready access to water in cases of fire, when sometimes treacherous hydrants fail. We believe this principle has been adopted on the Continent, but, we think, not exactly as we have here suggested, and it is certainly one that calls for the consideration of our public men. To consider the idea here put forth as one involving too great an outlay may be quite natural; but, upon investigation, the combination would be found less expensive than when erected separately, or according to that system of instalment-building which is too often singularly apparent in works supposed to have a pre-conceived and well-digested plan.

When properly patronized and appreciated, none so ready as the architectural profession, true to their principles of art-worship, to carry out a feasible suggestion. Our ardent wish is to see again revived in our public men that spirit of patronage and appreciation which caused cardinals to step lightly upon the threshold of a Raphael, and princes to court the smile of a Michael Angelo! To induce this much remains to be done by the members of the profession, whose rival interests too often clash, and whose competitions unfortunately in many instances savour too much of hostility.

In suggesting a design, our limited space prevents us from giving more than a general hint or so. To solve it practically is not our province; but when fully assured of its feasibility, we recommend it to the attention of those who by position or profession may be enabled to embrace it. R.

THE ROYAL ZOOLOGICAL SOCIETY.

IT is much to be regretted that public patronage as regards annual contributions is so sparingly awarded to this excellent institution; and we believe that were it not for the combined "pennies" of the working classes—the Sunday visitors—it would cease to exist altogether. The subscription of *One Pound* is a paltry consideration for the upper classes, and the £223 accruing from members' subscriptions during '59 and '60, if such were the sole dependence of the society, would be totally inadequate to defray the feeding expenses of even a small proportion of the animals. Much pleasure, instruction, and healthful recreation is afforded by a visit to these gardens; and it certainly is a stigma on our philanthropists that the resources should be so crippled. How far they are appreciated by the toiling artizans of our metropolis is evidenced by the fact that in the changeable month of April upwards of *six thousand* persons were at one time within the gates on a Sunday afternoon; and during the year the number admitted at the *penny* rate was 134,926. Items in the last report are so illustrative both of poverty and claims for consideration, that we subjoin them in the hope of the desired end being even partially attained by publicity.

"The Council wish that, in turning from the humbler ranks to those who, by wealth and education, are placed above them, they could report with equal truth of increased interest felt, or increased support afforded by the wealthy classes of our metropolis; but the treasurer's balance sheet shows no gratifying evidence under this head. On the contrary, although thirty-seven new members have joined the society during the financial year, yet so many more of our old members and subscribers have ceased (or omitted) to pay their subscriptions, that the funds received from subscriptions and entrance fees are less by £29 12s. than in the previous year. The whole income of the society last year from every source was £1,854 5s. 1½d. At the close of 1858–9 there was a balance of £68 3s. 1¾d. against the society; at the close of the present year the deficiency is £296 0s. 2½d. A new house for the Carnivora, capable of properly displaying the fine series of lions, tigers, and leopards, now owned by the society, is very much needed, but its erection has been year by year deferred for want of *the requisite funds*. New cages for some of the larger quadrupeds and birds are also very desirable. The condor, whose outstretched wings measure ten feet, is at present, of necessity, cooped up in a cage of a very insufficient size; so that the fine specimen we possess of this noble and costly bird is in danger of suffering in health by its present confinement, and cannot be considered as being adequately housed until a cage of at least four times the dimensions of the present coop be provided. At present the unprotected side of the pond, as reported last year, 'permits the escape of our waterfowl, and leaves them exposed to mischievous persons, and to dogs.' It also allows the free ingress of deer from the herd in the park, and exposes the ornamental shrubberies to destruction by those wayward animals. This subject has been repeatedly brought under the notice of the government, and is still before the Lord Lieutenant; and your Council are not without hope that the official difficulties may be speedily arranged, and the entire pond enclosed within the garden fence. 'Impressed with the idea that one day or other arrangements will be made by which these extensions of the site will take place, I have been induced to prepare the accompanying design (No. 1) in which they are comprised.'—(From Report of Decimus Burton, Esq., Surveyor and Architect, 6 Spring Gardens, London, October 27th, 1832.)"

PAPERING WHITEWASHED WALLS.—Apply, a day or two before papering, a solution of common glue to the walls, hot and thin, and as it grows thick, add more boiling water. The brush should be applied thoroughly (a clean white-wash brush is best), and the wall must be well saturated with the solution. In papering, mix flour for the paste, with a weak solution of glue. In this way you can avoid using thick paste, which is very detrimental to the beauty and durability of a papered wall.

IRON BUILDINGS.

A VERY instructive discussion on the employment of iron as a material for structures took place, somewhat recently at the Polytechnic Club, New York, which we substantially, and through favour of *Architects' and Mechanics' Journal*, present to our readers.

Mr. Ayres said that iron buildings belong to the present century. Prior to 1847, there was not in existence one iron house. At that time, at the corner of Centre and Duane-streets, the first iron building was constructed by Mr. Bogardus. He noticed various buildings which had previously been erected partly of iron and partly of other materials. Fire-proof buildings could be made of stone, brick, and mortar, but they would be limited in size, and extremely expensive where ground-room is scarce. There never was a decoration or ornamentation of any kind which could not be re-produced in iron : and many effects could be produced in iron which could not be produced in stone. The cheapness of the variety of form which could thus be introduced, would displace the tedium of uniformity, and thus we should be enabled to imitate the surrounding diversity of nature. The old classic models we could imitate, and were imitated, in iron buildings; and this extended the classic taste even in the construction of stone and brick buildings; for there had been more architectural display within the last ten years than for the two centuries proceeding. He summed up the advantages of iron buildings as follows :—

1. The great facility with which any architectural design can be carried out in iron.
2. Great economy of space ; inasmuch as a thinner column of iron is required to support a given weight than any stone column ever constructed. A cast-iron column would rise to the height of several miles before its own weight would crush it.
3. Economy of construction of foundations, and safety to the building, notwithstanding any accidental imperfections of a part of the foundations.
4. The facility with which the building may be removed.
5. Security against lightning, the electricity being diffused over so large a surface as to be harmless.
6. Facility of ventilation.
7. Admission of light through large openings.
8. Durability ; outlasting all other substances.
9. Incombustibility, rendering it invaluable for public buildings, and for many private buildings, for the storage of valuable papers, works of art, &c.

In rendering buildings fire-proof, especial attention had lately been paid to the interior work. The peculiar form of girder employed by Mr. Bogardus is two pieces of cast-iron meeting in the centre, to the bottom of which, cast two or three feet deep, according to the weight to be sustained, a wrought-iron rod is secured. The old beam was formed by springing the wrought-iron tie-rod into the cast iron arch above ; and there was danger of weakening either one or both of the materials used, particularly if sprung too tight. If it were too loose, the superincumbent weight might crush the cast-iron before it would take any tensile strain upon the wrought-iron. The advantage gained in the combination of the wrought and cast-iron, by making the cast-iron in two sections is, that if the cast-iron does not come close together, it cannot have any effect at all, but the cast-iron will have a bearing finally, and will be precisely as strong as if made so in the first instance. In the support of great weights, experiment has shown this form to be superior to any other. A girder twenty feet long, with two feet rise, will support sixty or seventy tons in the centre without any deflection at all.

Mr. Bogardus's building is not entirely fire-proof. The floors are wood. The intention was, that if the building should burn down, the walls should stand. If an iron building be put up tied together by wooden braces, or the columns resting upon wooden floors, the building would fall as soon as the floors and the braces were destroyed. In the Crystal Palace the supports were of wood ; and the same is true of a great many iron buildings. If we are to have iron buildings, we ought to have iron buildings that will stand, even if all of the wood-work should be destroyed by fire.

Mr. Whittemore stated that in 1853 or 1854, a firm in Chicago put up a building with an iron front eighty feet in length. It was put entirely up, and stood three days. He happened to be standing within fifty feet of it when it came down in the street. There had been several instances since that time of fronts falling completely out. One front, on Lake-street, fell from the heat of a fire opposite. He ascribed the falling to the crumbling of the mortar by the heat, where it fell. It was supposed at the time that the heat was the cause of its falling.

Mr. Ayres—There is no expansion in iron buildings under any possible circumstances.

Mr. Whittemore—I know that at Chicago, I drew a building together some fifteen inches, merely by the expansion and contraction of iron. It bulged out fifteen inches, and was drawn together by nothing else than the contraction of the iron. It was for the firm of Geo. Letts & Co. ; the building was on Water-street.

Mr. Ayres—The building of Harper & Brothers', in Pearl-street, which has been standing there some years, has a front of seventy-five or one hundred feet in length, and it comes up against the brick wall at each end. There never was any expansion of that front to lessen, or contraction to increase, the distance between that front and the walls adjoining.

Mr. Garbonetti said that a building might be fire-proof if kept empty ; but if Harper's building should take fire, or a fire should break out in the contents of the building, they would be in an enormous oven, and the destruction of the property would be more certain than if the building were stone or wood. It was not the stone, brick, or wood of a building which usually took fire ; it was the contents of the building ; and he considered an iron building as more dangerous in case of a fire, for paper, or dry goods, or any inflammable material, than stone. The expansion of Harper's building, if the contents were on fire, would be enormous ; and he had no doubt would force out the walls of the surrounding buildings ; so that an extensive iron building would not be, in that respect, a very good thing as regards the surrounding property. The heat would be concentrated.

Mr. Ayres knew of one instance where the contents of an iron building had been consumed. It was a house in San Francisco, stored from the cellar up to the roof with all sorts of combustible materials. The whole inside was burned out ; for the floor was not fire-proof. After the fire the building was examined, and there was not a bolt sprung. The fire companies endeavoured to push down the walls, and could not do it. It only had three sides of iron, and the other side had fallen out. The next morning, thinking it dangerous to leave those three walls standing, they fastened ropes to different parts of the building, to pull it down, but it was too strong for them. The building was then taken down, piece by piece, and moved to another site, and put up exactly the same as before. There was no damage there from the expansion or contraction of the iron, nor did the water thrown upon it crack it.

Mr. Whittemore stated that a button factory was built in Chicago, two and a half years ago, and it had not been built six months before its contents took fire. It was heated so hot that it drew every bolt-head out, and started every screw in the building. The building came down one solid mass.

Mr. Reed stated that he had to-day accidentally seen a statement in the *Mechanic's Magazine* for 1824, that there was an iron light-house erected upon the wharf in Glasgow in that year.

Mr. Johnson spoke of iron buildings constructed prior to 1847 in this country. He had seen in London, in 1834 or 1835, a gas house entirely of corrugated iron and iron rods. As to these iron buildings being fire-proof, he thought that if the Cooper Institute should take fire below, probably the interior of it would all burn. Casting, when hot, has nothing like the strength it has when cold.

Mr. Godwin mentioned having seen cast-iron columns imported into this country, a good many years ago, and described the plan tried by John L. Mott, many years ago, casting square blocks of iron, in sections, and tying them together by a rod going down through the centre.

A gentleman remarked that with the construction adopted in fire-proof buildings, one floor might be burned entirely out, and the other floors might be saved. There was danger of cast-iron breaking from the sudden dashing on of cold water ; as when a stove is hot, the top may sometimes be cracked by opening the door and thus suddenly cooling the iron. Whether a body of iron like an iron column could be so broken must be determined by experience. When the heat is nearly at the point of fusion, the column must expand in the ratio of about one eighth of an inch to the foot ; for it was found that melted iron uniformly contracts in that proportion, and stove castings are calculated to be so much smaller than the pattern.

Mr. Seeley—I think Mr. Bogardus and Mr. Ayres would not dispute the fact that iron will expand by heat at the rate that is mentioned here, or that the expansion is irresistible. If you have a building a thousand feet long, it is going to expand, between ordinary ranges of temperature, nearly an inch If one end is fastened, the other end will move an inch, and nothing will resist it. If Harper's building is made in the way represented here, so as to be a firm structure, as if it were of one piece of iron, and if one end abuts against a brick wall firmly, it must move something at the other end, if there is anything there to be moved. If it abuts closely against two brick walls, they must be moved. If they are so joined to the iron building as to be a part of it, they will be pushed along. All matter expands by heat. Some expands considerably, though not so much as iron.. This was very well shown by Prof. Horsford, at the Bunker Hill Monument. On the inside he suspended a plumb line, and found that when the sun was shining upon one side, it leaned the other way, away from the sun. The side of the monument upon which the sun was shining would be so extended that the whole monument would sway northerly, opposite to the sun. But in very many iron structures, some account is practically taken of expansion, provision is made for it, and the amount is made visible to the eye.

It was stated at the last meeting, that it was the most modern practice in laying rails, that they should abut as closely together as possible, and I have asked a gentleman connected intimately with one of our largest railroads, who assures me that there must be a little error there in, for that he had noticed a rail damaged from the expansion when the rails were laid closely together, and curving upward from the sleepers.

Mr. Ayres—With perhaps a larger experience than any man in the whole country, Mr. Bogardus has never known a single instance in which the iron has expanded to such an extent as to make it necessary to take that into account in constructing his building. We are putting up a building now 700 feet long. No account is taken of expansion, nor has any expansion occurred. It was built here in cold weather, and sent south in very warm weather. The difference of temperature might amount to 158 dgs., yet there is not the slightest indication of any expansion, nor has there ever been in any building that has been put up. We may come to this conclusion, that if, in view of all the experiments that have been made—for we consider them experiments, although they had not that end in view—we can never discover that in any instance there has ever been the slightest variation, and we may assume that, for all practical purposes, there is never any variation; and consequently, the contraction or expansion of iron, as applied to iron buildings, cannot have the slightest bearing upon the subject.

Mr. Whittemore inquired if Mr. Bogardus ever used the expansion or contraction of iron in building; and alluded to the practice of shrinking collars on to their places to ensure a snug fit.

Mr. Ayres—Undoubtedly we do, in the manufacture.

Mr. Whittemore—If it will shrink in that instance, why not in another?

Mr. Ayres—In making castings, of course we take it into account; and in machinery we undoubtedly shrink on collars.

Mr. Howe reconciled the theories in this way: that the expansion is very slight, and that the resistance to that expansion, when the building is put together, and upon a firm foundation, is sufficient to prevent the force of the expansion from being felt. Perhaps the building does not move, but is held by its weight from assuming the extended form which it would otherwise assume by the change of temperature, unless the heat is greatly increased.

Mr. Seeley—I can very readily perceive that if you put iron in a skeleton form, and make a building in the shape of a cube or a parallelogram, it expands as a whole, and proportionally in every direction. If you increase its length by a thousandth part, by heat, the height is increased by a thousandth part, and the relative proportion of the parts is not varied. The building does not change its shape. Mr. Ayres will not doubt that if he has a building 700 feet long, and an iron roof of a large span, and extending over the whole 700 feet, a very little expansion would throw his ends out. Wherever iron of much length is introduced in the form of an arch in such a way as that, the expansion must be taken into account; and if they have not taken this large expansion into account, it is only, I think, because, from the peculiar manner of putting up their buildings, the parts are at right-angles to each other, forming systems of parallelograms.

Mr. Ayres—The roof of that building covers 150,000 square feet. We have madeno provision whatever for expansion, and are not very apprehensive that it will push the walls down.

Mr. Garvey reminded the Association that there is expansion from other causes as well as from heat. Practically, the expansion from the changes of the weather is insignificant. The expansion of wood from hydrometric changes of the atmosphere leads to much greater results. Nearly all the cracking in buildings is caused either by the expansion or contraction of brick, mortar, wood, and stone. The expansion of iron by heat is utterly insignificant in comparison with the others. Take a piece of wood in dry weather of a given length, and if the weather becomes moist, there will be an appreciable expansion in length, while a piece of iron, with the most minute philosophical examination, shows no expansion whatever. The question with regard to building was merely as to relative expansion. It is said that "an inch on a man's nose is a great deal;" but an inch in a hundred feet is not a great deal. A dozen joiners going over it, one after another, with their rules, would differ nearly by that amount in their measurement. The expansion, therefore, is altogether insignificant in this respect. There is not a wall about a building that does not expand or contract more or less. If one part expands more than another sufficiently to throw the wall beyond its base, it comes tumbling down. Again, the joints in iron buildings, frame them as closely as you can, are not absolutely in contact. There is no such thing as bringing the parts into absolute contact, and those minute spaces must be filled up by the expansion before it can exert a dangerous thrust in either direction.

With regard to the danger of fire, the material of the shell will by no means render a building fire-proof. The great danger in modern buildings is, that the partitions create a flue already charged with kindling and fire wood. They are generally put up with studs, leaving an air passage between them. Shavings fall in, and fragments of chips, and bits of laths, and the partition is wood. Start the fire, and you have it ready to blaze, and a draft to the very top of the house. Every apartment should be cut off from every other to prevent this danger. But even a building wholly fire-proof is not perfectly secure from fire. Any building may be ruined by filling it with cotton, gunpowder, or other combustible material, and setting fire to it. Mr. G. proceeded to speak of the advantage of iron in the increased facility of the introduction of light and air, which was rendered necessary in the advancement of civilization. He would take exception, however, to the model introduced, placing one column directly over the other in the manner exhibited.

Mr. Seeley stated that wood expanded more than iron, or any other metal, from hydrometric changes; but that it was at the same time pliable and elastic, so that the expansion could be easily resisted, while the force of iron was practically irresistible. The hydrometric expansion of wood was chiefly across the grain—in length it had been stated to be nothing at all. The wood in buildings was generally placed so that the strain would be lengthwise.

Mr. M. Haskell exhibited specimens of iron roofing. He said that iron for roofing was so much exposed to oxydization that some special means must be used to protect it from the weather. These specimens were of iron, coated with india-rubber which was dissolved in linseed oil, and brought to a liquid state. The iron was heated to 350 dgs. Fahr., immersed in theliquid, taken out, and dried in a drying-room or oven. It would thus be thoroughly covered with a substance impervious to moisture. To allow for the expansion and contraction of the iron from heat and cold, the joining was so made as to allow an expansion of 1-16th of an inch. The plates are two feet wide, and nine feet long. Each plate has the two sides turned up at right-angles, and projecting pieces at one side, by which to nail it to the roof. The turned-up sides are folded, in putting it on, one over the other, and then both together, so as to make it perfectly tight. After the whole is put on it is painted with india-rubber paint, coloured as desired with various pigments, no drying being generally used. The roof is thus perfectly water-proof and tight. The india-rubber paint never contracts or blisters. Mr. H. stated that when the Crystal Palace was burned, there were on exhibition several large glass jars of the india-rubber paint. The glass was melted, and the paint was baked upon the outside, but inside it was perfectly green. It would not burn even under these circumstances.

Mr. Vanderwede said, that if a beam were contracted by cold, it might be prevented by great weight from recovering its former length. So if a horizontal beam were exposed to a great weight and expanded by heat, it would more easily bend, and might not become straight again.

ANSWERING LETTERS.—That a large proportion of the community seems to be totally ignorant of, or if not so, what is more culpable, wilfully to disregard the courtesy of "*answering letters*" is certain. Yet, strange to say, an infinitely small proportion of *that* proportion are so blind to their own interests as not to become ready correspondents when the subject refers to their own immediate profit, and that the position of creditor and debtor becomes reversed. Write, enclosing an order for goods, or suggesting a benefit, and you receive *per return* an acknowledgment of "*your favour*," but write, enclosing an account for money due, and you *may* write and *re*-write, rejoicing in the privilege accorded to you by your *silent* and *absent* friend of adding to your taxes, and increasing the Queen's Revenue by an unnecessary and useless destruction of postage stamps. Probably *we* are not singular in this—indeed we *know* we are not—but touching ourselves, the discourtesy complained of and from quarters one may have the least right not to expect it, becomes more apparent. Proprietors of periodicals or newspapers, or those whose avocations impose on them much correspondence, learn a *trifle* of human nature after a very short while, experiencing politeness often from the otherwise ignorant and lowly, friendly considerations, and off-handedness of dealing from the stranger; while from those whose education ought *to teach them better*, and overwhelming with professions, they fail to extract even "the favour" of a line, and discover that friendship of the *tongue* and the *pocket* are very widely different. Three, four, probably half-a-dozen letters upon an uninteresting subject may be addressed to some without any notice whatever, but if perchance the recipient be encountered personally, the diplomatic alternative is adopted either of feigning grievance at being "*so dunned*," or the opposite in *suaviter in modo* style of taking your arm, apologising to "my dear friend" for *seeming neglect*, but "really being overwhelmed with business, had not time to reply," &c., &c.

FATAL EXPERIMENT WITH SAFES.

SOME experiments as to the burglar-resisting and gunpowder-proof qualities of safes came off recently at Burnley, near Manchester, and one of them resulted unfortunately in the death, by explosion, of a fine child, aged seven years, by name Robertshaw Frankland. The safes tested were respectively 26 inches by 20 inches by 20 inches, the manufacture of Messrs. Milner, of Liverpool, and 33 inches by 25 inches by 25 inches (fitted with an improved patent "*Ne plus ultra lock*"), by Mr. Price, of Wolverhampton. Mr. Davis, one of Milner's local agents, declared that their safe was not one of the most recent manufacture. According to the *Burnley Advertiser* we learn that Mr. Price delivered a lengthened address on the principle and merits of his safes, admitting that Milner's small locks are gunpowder proof, but denying that the lock chamber is so, and that Milner's representatives challenged Price to test theirs with *his*, which the latter declined, as also a request to allow the chamber of the lock to be examined. Mr. Freestone, a tradesman from Nottingham, undertook to open Price's safe in ten minutes, but made two ineffectual attempts with gunpowder; whereas, Price's assistant applying a fuse to Milner's, it was moved several yards from its position, the door blown completely off the hinges, the dovetails of the body in several places drawn out of the lock-chamber, and the wooden filling blown to pieces. It took 7½ minutes to drill the hole, through which about ten ounces (another account states about two pounds) of powder were put. The third safe tested, however, was Price's, and was blown to pieces; and at this stage of the proceedings the lad lost his life.

The *Liverpool Courier* gives the following version of the affair:—

> About a fortnight ago, a Mr. George Price, of Wolverhampton, who has set himself up as a rival of the well-known firm of Milner and Son, of the Phœnix Works, in this town, appeared at Burnley, with two safes of his own manufacture, for public testing, announcing that they were fitted with his "*ne plus ultra*" lock which defied the efforts of burglars, whether aided with crowbar, drills, or gunpowder, and offered any one present £50 who should be able, by any means, to force them open on the ground. A working mechanic belonging to the town stepped forward, and boldly accepted the challenge, stating that he would blow them open by gunpowder. Mr. Price defied him to get gunpowder sufficient either into the lock or chamber to force open either safe, and the man set to work with one of them, which was placed on its back for the purpose. The man, however, managed to get so much powder into the first lock that Mr. Price declined to let him fire it, but defied him to get as much powder into the other lock, if the safe was placed on the ground in the ordinary position, with the door outwards. Notwithstanding this change of position, however, the operator succeeded in getting a still larger quantity of powder into the lock of the second safe, but Mr. Price still declined to let him fire either, alleging as an excuse that there had evidently been some mistake in the manufacture of the locks, which he could not explain without careful examination. The operator accordingly claimed the £50, but Mr. Price refused to pay it to him under the circumstances, and the experiments terminated amidst the loudly expressed dissatisfaction of the assembly. Subsequently, Mr. Price published an explanation in the Burnley newspaper and elsewhere, to the effect that his men in fixing steel nozzles of peculiar construction on the two locks, had neglected to make them long enough to go completely through, and so destroyed their intended value. He announced, however, that he would make a renewed trial on Monday, 30th April, with a new safe made for the occasion, and fitted with an "improved" *ne plus ultra* lock, which should be really impregnable. It was further intimated that Mr. Price would, in order to show the superiority of his safes "blow up" one of Messrs. Milner's *best* construction, on the ground. Accordingly a very large concourse of people assembled on the spot selected for the trial, and two o'clock, p.m., precisely, had been announced by Mr. Price as the hour for the commencement of what he facetiously termed in his placards and handbills—"This great and highly interesting event—the Fight for the Championship in the construction and manufacture of drill-proof and burglar-proof safes."
>
> Mr. Price had on a lorry a new safe of his own construction, and one purchased some eight or ten days before from Messrs. Milner's agents at Manchester, which he said he would blow up, while defying any to effect the same with his. Messrs. Davis and M'Clunnan, the agents of Messrs. Milner at Manchester, had one of the *latest* constructed Phœnix safes on another lorry, which they on their part defied Mr. Price to open. Mr. Price, however, declined to have anything to do with the *new* safe, but repeated that he would blow up the *old* one. A good deal of wrangling took place as to how the tests should be conducted, and Messrs. Milner's agents admitted that the safe Mr. Price had might be blown open by a person thoroughly understanding its construction, and knowing how to get in the powder. Mr. Davis requested Mr. Price to consent that the chambers of the two best safes of either construction should be examined, but Mr. Price declined to exhibit his safe in this manner, saying that he had improvements in the lock and chamber which he had not yet patented, and must therefore keep secret. Notwithstanding the admission made by Messrs. Davis and M'Clunnan, Mr. Price and his assistants proceeded to drill and insert gunpowder into the door of the *old* Milner safe, and blew it open without accident, the door being wrenched off, and the body of the safe thrown a distance of a few feet, the lock, however, remaining uninjured. Mr. Davis pointed out that this was by no means a fair test, for a burglar would not have that intimate knowledge of the interior construction of the safe which Mr. Price's examination had enabled him to acquire, nor would he venture, for fear of detection, on such a serious explosion as had been necessary to rend open the safe in the present instance.
>
> While these proceedings had been going on the utmost excitement was displayed by some hundreds of persons, chiefly working men, who were assembled on the ground, and there were loud cries to try one of Price's *old* safes by a similar test. A safe recently purchased from Mr. Price's agent in Burnley had now been procured from Mr. Robertson, a local manufacturer, and upwards of a pound of powder was introduced through the lock. The charge was fired, and the immediate consequence was, that the safe was utterly blown into fragments, which flew about in every direction. One piece of thin plate iron, about a foot square, flew off at right angles from the side of the safe and struck the boy, who was crouched in a corner some dozen yards off, cutting away the left portion of the upper part of his skull.

The jury on the inquest found a unanimous verdict of "accidental death," coupled with an opinion, that "*both parties deserve severe censure for attempting such dangerous experiments in presence of the public.*"

The father of the deceased accepted from Mr. Ratcliff, who fired Price's safe, £15 15s. as compensation *for the loss of his child!* funeral and other expenses being likewise paid.

VALUATIONS AND TAXATIONS IN THE NORTH.

IT is not only a matter of notoriety that the tenement valuation of Ireland is still incomplete, but that it is retarded by the exclusion of competent valuators, that the period of service of favourite employées might be protracted. We know of some efficient parties who applied for employment, but could not obtain it, and they complain to us bitterly of the injustice so perpetrated. This is neither just to those whose abilities entitle them to at least "a share," nor to the public whose interest must materially suffer by such a dissatisfactory state of things. In Belfast there are no less than six bodies having powers to tax the inhabitants. The Vestry Poor-law Guardians, Harbour Commissioners (power to tax indirectly) Town Council, can make their different rates. Police, Borough and Bath-house Rates, Water Commissioners, and lastly, the Grand Jury. Three of those make valuations, or pretend to do so for themselves, *i.e.*, Poor-law Guardians, Town Council and Water Commissioners, and the Grand Jury use the Poor-law Valuation. All these taxing authorities seem most anxious to keep their valuations at the maximum point, in which they are greatly assisted by the Town Council Valuator, and celebrated collector of the parish rate in days of yore, when political contests were fierce and frequent. We hope the Chief Commissioner of Valuation will push forward his work with a little more alacrity, and introduce a uniform and unimpeachable valuation into the hands of these taxing bodies with as little delay as possible, and deliver the inhabitants from the tender mercies of them and their valuator, at least so far as regards valuation. The utmost extent of the rating power of the Town Council is 16d. in the pound on dwelling-houses, and the rate demanded is seldom less. This year it is 14d., but in order to increase their income (for it seems that no corporation can ever satisfy itself with the amount squeezed out of the pockets of the people) they cause the valuation of houses to be made at the full sum paid by the tenant, the landlord keeping the premises in repair, and paying insurance and income-tax. This corporate body acted similarly for many years, until a decision of the barrister compelled them to reduce their valuations to that of the poor-rate.

THE ROUND TOWER OF CLOYNE.*

THE ancient and interesting town of Cloyne is situated in the barony of Imokilly, and county of Cork, from the city of which it is distant nineteen miles; it is seated in the heart of a rich and highly cultivated country, being embosomed in gently rising hills, and does credit to the choice of the ancient fathers who here took up their abode in very remote times.

Cloyne is known in our annals as Cluain-umha, or Cluain-vania, the latter being a Latinizing of the former; Dr. O'Brien describes *cluain* as signifying "a plain, a lawn, a remote or retired situation," and *umha*, "a cave, den, grave." Thus it is often styled "Cluain of the Caves," as there are in the immediate neighbourhood caves of remarkable extent and beauty.

The earliest notice we have of Cloyne is connected with its ecclesiastical foundations, as we find that in the sixth century a bishopric was founded here by St. Colman, son of Lenine.

It is a matter of surprise and regret that we know comparatively little of these puzzling and singular structures. Start not, reader! I admit that volumes have been written on them, that lives have been spent in poring over the dusty tomes of antiquity, to ascertain their history, their builders, and their uses; that much acerbity of feeling has been created, and much intolerance exhibited, in the pursuit of these investigations; but I still maintain that those learned and dogmatic Pundits have begun at the wrong end, and are, in consequence, no nearer the truth than when they commenced. As contributions to our general stock of antiquarian knowledge, their labours are not without their uses, but as attempts to set at rest the origin and uses of these structures, they have signally failed. It has always appeared to me that the true key to the mystery existed in the towers themselves, and that, until a careful examination and measurement of all or a great number of them were taken, and a critical analysis and comparison of them prepared in reference to their exact forms, proportions, details, and material characteristics, and a thorough exploration and examination of their contents, collecting all the traditions connected with them; I repeat, until this has been done, we are not in a position to form a sound and credible opinion upon them.

The best practical account that we have of them is from the pen of Mr. Wilkinson, in his "Practical Geology and Ancient Architecture of Ireland." In the section of the work devoted to architecture, he gives a tabular account of the principal towers, yet this is deficient in many respects. In several of the towers he gives no measurements; in others they are only conjectural; much of the detailed information is valuable as being the result of his own personal observation, particularly his descriptions of the materials and masonry, for which branches of the subject he was eminently qualified. It would, however, be utterly impossible for any one individual (unless he devoted a life and a fortune to it), to make a thorough examination of these structures, such as I have described.

Dr. Petrie, in his "Treatise on the Round Towers," has given drawings and accurate descriptions of the doors and windows of several of them; but his work is very deficient in plans, elevations, and sections, and in that practical criticism which, after all, is the safest and most rational foundation upon which to erect a credible theory.

In his work, professedly on the Round Towers, he has given us no description whatsoever of the Cloyne specimen; his only allusion to it is an unsuccessful attempt to invalidate and turn into ridicule the researches of the South Munster Society of Antiquaries, who in the year 1841 excavated the base of the tower, and discovered traces of interments therein.

Mr. Windele, in his very valuable and interesting work on "Cork, Killarney," &c., has given by far the best description of this tower; it is evidently the result of careful personal examination, and not of the wholesale copying system indulged in by most of the writers who have preceded him on the subject, as is evidenced by the above extracts.

The tower stands nearly opposite the west end of the present cathedral, from which it is distant 30 yards; its dimensions are as follows:—Diameter of tower at sill of doorway, 9 feet 2 inches; thickness of wall at same, 3 feet 7½ inches; diameter of tower at upper floor, 7 feet 2 inches; thickness of wall at sills of upper window opes, 2 feet 9 inches; height of tower to top of modern battlement, 100 feet 2½ inches; the ratio of batter in the external face of tower is about 1 in 44; height of sill of doorway over plinth, 11 feet 2 inches; height of plint, 7 inches; projection of plinth, 5 inches. The doorway is perfectly cyclopean in character; it is quadrangular, with converging jambs and massive lintel; its dimensions are—width at sill, 2 feet 1 inch; at lintel, 1 foot 10½ inches; height, 5 feet; its massive dressings are of red sandstone, and on its left hand jamb are several deeply indented scores, to which I shall hereafter allude.

The tower internally is divided into stories by seven off-sets taken from the thickness of wall, the inside face of which is built in a curious manner; from each off-set the wall batters outwardly to about half the height of the story, when it batters in again as it approaches the next; so that, drawn in section, the internal line of wall would show a zig-zag outline. At present there are wooden lofts resting on these off-sets, communicating by ladders. The masonry is of a yellowish brown sandstone, in spalled rubble work, not built in courses; the stones large, and dressed to curve of tower; the workmanship is good; a small portion of limestone is used at the north side, a good way up; and a few blocks of red sandstone are used through the facing.

This tower was originally crowned by the usual conical stone roof, which is stated to have been destroyed on the night of the 10th of January, 1749. The circumstance is thus given by Mr. Crofton Croker, in his "Researches in the South of Ireland," p. 243:—

"A thunder-storm with lightning passed through the county of Cork on the night of the 10th of January, 1749, in a line from west to east, and, after killing some cows in a field south of Cork, struck the Round Tower of Cloyne, used as a belfry to its Cathedral. The electric matter first rent the vaulted arch at the top, threw down the great bell presented by Dean Davies, together with the three lofts, and, descending perpendicularly to the lowest floor, forced its way, with a violent explosion, through one side of the tower, and drove some of the stones, *which were admirably well jointed*, and *worked into each other*, through the roof of a neighbouring stable. . . . The conical stone roof destroyed by this accident was never replaced, but the height of the tower was lowered more than 6 feet, and an embattlement substitute!"

I find, however, that this version of the destruction of the original roof of the tower must be wrong, as by reference to Ware's "Antiquities" we find a plate of "Cloyn" Cathedral and Tower, which exhibits the latter with a battlemental parapet, as at present; the date of this edition is 1739, that is, ten years before the above recited accident; it is, therefore, quite evident that the destruction of the original roof must have taken place previously to 1739.

It is stated that, in 1736, the tower was struck by lightning, the conical roof shattered, and the bell dismounted, falling through three of the roofs; it must have been immediately after this that the tower was repaired, as shown in Ware, 1739.

The tower was one time used as a prison; a man named Colbert, being confined therein, got out on the roof, and descended outside by means of the bell-rope—a daring feat.

The Round Tower at Cloyne is locally known by the Irish-speaking people as Giol-cach; the same term is locally applied at Ardmore, at Kineth, and at Ratto, in Kerry. I was never more struck with the poetic applicability of this term to our Round Towers than at the latter place, when I stood on the ancient causeway opposite the tower, and heard the same name applied to the tall, slender, symmetrical pillar, with its perfect conical spire, as to the tall graceful reeds, with their spiral feathered caps, which lined the banks of the Brick; and of the canal which runs up nearly to the base of the tower. Dr. Petrie (p. 397 of his work) says that by "Giolcach is understood a bell-house, and which is obviously a local corruption of Cloigtheach, or Cloichtheach." Now, I am strongly inclined to think that no one understands Giolcach to be a bell-house saving the Doctor himself; the Irish-speaking people at Ratto do not so understand it; they call it a Giolcach; neither do they so understand it at Cloyne, or Ardmore. As to its being a corruption of the Doctor's favourite term, Cloigtheach, or Cloictheach, it is obviously no corruption of any word, but a pure, simple, and very illustrative Celtic term, as the Doctor will see by reference to O'Reilly's "Irish Dictionary;" "Giolcach, a reed, cane, broom;" and I would further intimate that the way in which the word is pronounced is quite opposed to Dr. Petrie's corruption of the term, being thus—"Quill-cogh," which is far removed from either "Cloig-theach," or "Cill-theach,"—another reading advanced by Mr. E. Fitzgerald in your Transactions for March, 1858, p. 223.

The ancient Irish are not singular in their illustrative mode of nomenclature. Thus the Romans derived the name of a similar class of structures, the obelisk, from *obeliscus*, a javelin.

A nautical compass has been lately invented, which is so constructed as to give at all times the specific leeway of a vessel. It may be placed on a table in the captain's cabin, and will inform him of the least deviation from the course to which the vessel may be heading.

Mr. Maclise, the *Athenæum* says, has determined to paint his great cartoon, in Westminister Palace, in the German fresco—that is in the water-glass medium.

---

* Collected from a paper read by R. R. Brash, Esq., before Kilkenny Architectural and Archæological Society, and published in vol. ii., part ii. of the Transactions.

THE NEW PULPIT, CASTLE CHAPEL.

A very beautifully designed and elaborate pulpit in Caen stone, as illustrated in this number, has been recently erected in the chapel attached to the viceregal residence in this city. Most of our readers are, doubtless, aware that the building was erected after plans by the late Francis Johnston, R.H.A., Architect, between the years 1807 and 1814, and that it is in the Gothic style of the Decorated period. The interior displays some beautiful carvings by eminent artists of the day, together with a handsome groined ceiling, stained glass, and other ornamentation.* It was necessary therefore, that all the internal fittings should harmonize in style, so as not to affect the beauty of the *toute ensemble*, and the old pulpit being deemed unsuitable, Messrs. Hardman and Co., of Birmingham and Dublin, were entrusted with the designing and execution of a new one. We anticipate, with some confidence, that our approving opinion of the manner in which this firm have fulfilled their task will meet with ready endorsement from those who either inspect the design, as shown in our illustration, or the execution of the original. It is placed at the end of the nave adjoining the communion rail, and is polygonal on plan, the dimensions of the preacher's compartment being in clear 3 feet 4 inches. The height of the clustered shafts sustaining the superstructure is 4 feet, and the total height from the ground to top is 9 feet 8 inches. The figures represent the four Evangelists and St. John the Baptist. We understand that the entire cost was about £120, a sum which, considering the delicacy of the execution and the beauty of the sculpture and the carvings, seems to be very moderate. It may not be amiss to add, that though this work bears the *impresse* of English paternity, it is in reality not so, but is essentially an *Irish* work, in all its departments, even to the illustration, which was reduced, drawn, and engraved (from a photograph by Simonton and Millard) by Mr. George Hanlon, of Rathgar.

KINGSTOWN.

Foremost in the category of "noted spots" whereon the hand of nature has been more than ordinarily bountiful in disseminating the picturesque element, is the subject of this notice; but as the most vivid delineations of the poet's pen and the artist's pencil, in depicting the beauties of "Irish scenery," pale into insignificance before the stern reality, *we* dare not—sensible of our inability—attempt a coloured picture, but confine ourselves merely to the rigid outline of those features coming within our immediate province. Thanks to the genius of steam—that modernizing giant—thanks to the progressive development of the age, and the professional skill of modern engineers and architects, the poor fishing village, the asylum harbour of "Dunleary," has been metamorphosed into a great highway between this and the sister kingdom, replete with artificial as well as natural beauty! An important and populous business town—with outskirts thickly studded with princely mansions, handsome ecclesiastical, hotel, club, and other buildings, and a noble harbour to boot, with outstretched piers and quays, containing an area of some 250 acres, wherein the stateliest craft afloat may ride—has sprung into existence. Of the very recent works, we may remark, that the new pier for the conveyance to and fro of passengers and luggage direct from Westland-row to the vessel in fifteen minutes, attains a desideratum, and reminds us of a similar arrangement at Folkestone. The four powerful steamers, with guaranteed speed of 20 miles an hour, to ply from 30th inst. between this port and Holyhead will assist in the achievement of a miracle in transit—11 hours from Dublin to London—at which the Dominies of our age may well exclaim—"Prodigious!" Quoting from the statement of the respected Chairman of the Town Commissioners, and Mr. Reilly, when urging upon the Chief Secretary the claims of Kingstown to be made a borough, we observe that—

> "The population of Kingstown is 21,000, the valuation £50,000, and the area 923 acres." "It is an important and rapidly rising town. During the last three years 370 houses have been built in it, and there are 80 on the stocks."
>
> "The valuation of the electoral division has increased by £10,000 since 1857. Of that, £4,255 was an increase within the municipal boundary, and the valuation of the entire is now £60,000. The number of houses built in Kingstown in 1857 was 40; in 1858, 60; and in 1859; 120. There are seven churches in Kingstown, and there is still a cry for church accommodation. There is one bank and another is spoken of. Dalkey, in the immediate vicinity, contains a population of 10,000. There are but five boroughs in Ireland, including Dublin, that exceed Kingstown in valuation, population, &c., and there are ten Irish boroughs the aggregate of which are only equal to it in those respects. House rents in Kingstown have nearly doubled within the last seven years, and the average valuation is £28, a circumstance unparalleled in any other town in Ireland. The rapid increase of houses in Kingstown is the more extraordinary on account of the impediment to building speculations arising from short leases. The building leases there are only for forty-one years. During the last three years longer leases had been granted than before, but these are not given on the liberal terms on which Mr. Sidney Herbert granted *his* leases; for in Kingstown a shilling a foot was added to the present rent for the residue of the old lease when a renewal was granted As Kingstown is forcing itself into importance, notwithstanding these adverse circumstances, it deserves encouragement from the Government. It is the duty of the Government to assist those who assist themselves. Ireland is accused of being devoid of enterprise and industry, but the inhabitants of Kingstown have proved that they possessed them in a greater degree than any other town in the United Kingdom."

RESTORATION OF ST. PATRICK'S CATHEDRAL.

It would be ungracious to take exception to the motives which induced Benjamin Lee Guinness, Esq., to volunteer single-handed the wherewith to restore from impending ruin this time-honoured relic; but the possessors of worthy spirits and generous hearts are not always proof against errors of judgment. Such at least would it seem to be, and in this instance we cannot attribute to the usual penny-wise, pound-foolish fallacy prevalent, the absence of professional supervision in the carrying out of a work, which the very act of the benefactor proclaims to be one of national moment. An amateur of taste and discernment *may* try his hand somewhat successfully in adapting the internal arrangements of his mansion to suit his domestic requirements, or he may, peradventure, even do the artistic in matters of decoration, with a skilful painter at his elbow; but to tamper, by way of restoration, with a venerable edifice—whose every detail speaks a history—and without competent professional aid, would be quite unpardonable. Already has the structure in question been so thoroughly vandalized by experimentalists, that with example staring in the face, the omission is doubly culpable, and the continuance of the system would be but a perpetuation of monstrosities, alike injurious to the cause of architecture, and a stigma on our national taste. Rumour says that £20,000 are to be expended in the so-called restorations, but a reliable authority informs us that if *double* the amount be *requisite*, the inexhaustible coffers of the philanthropic brewer and ex-alderman will supply it. Seriously must we ask, therefore, is this important outlay to be incurred without *a head* to direct the operations of the builder, who in his *own* province, we must advance, is fully up to the mark, and too respectable a man to ignore the rights of others by undue assumption? For the present we defer touching upon the nature of the proposed works, being only in a position to communicate an idea thereof, *vague* as any of the parties concerned, donor or employées, can form—strange, yet true! and equally true, that in this state of bliss the operations have actually commenced.

Civil Service Estimates.—The total cost of public works and buildings during the financial year on which we have entered is estimated at £621,990, showing a decrease from last year of £171,854. A large portion of this decrease arises from the diminution of the expenditure on Holyhead Harbour, which absorbed £80,000 last year, and will only require £30,000 this year. £24,130 is saved in the expenditure on probate courts and registries, the cost of maintaining which during the year will not exceed £5,000. The large expenditure of last year on Port Patrick Harbour is almost totally extinguished, and a saving of £20,000 thus effected, and £18,000 are saved in the expenditure of the new Houses of Parliament, which are expected to absorb £39,597. Of the thirteen items in the estimate, all but one—that of "Kingstown Harbour"—require a smaller disbursement than they did last year, and in the exceptional case the increase is trifling.

OF THE
UNIVERSITY OF ILLINOIS

ARTISTS IN "THE MINSTER"—THE LATE SIR CHARLES BARRY—HIS FUNERAL.

RICH as are the associations of the "Minster" with names in almost every path of renown, it seems to fail in respect of painters. Sir Godfrey Kneller, a native of Lubeck, who painted for Charles the Second, James the Second, and finished the Court Beauties for William the Third, though of a gay and convivial turn in life, was so eclectic, not to say irreverent, as to his grave, that when the honors of Westminster were spoken of he would not hear of such a disposition of his remains; so that, although commemorated here, they really lie at Twickenham. But among the men of science are Sir Isaac Newton, James Watt, Sir Humphrey Davy, Telford, and Stephenson. There is Banks, the sculptor, and the prince of sound, Muzio Clementi, with Arnold, Burney, Blow, and Croft. Of architects may be mentioned:—Robert Adam, the chief of the brothers, or "Adelphi," who, after designing many monuments for others, was laid to rest in 1792; Sir William Chambers, in whose hands Palladian architecture reached its culminative point for the time in Somerset House, and who it seems was a Swede by birth, though of Scotch descent; and James Wyatt, who has been occasionally styled "the great," more as it would seem from personal and general qualifications than from the transcendent merit of his works.

The importance attached by the ancients to the performance of funereal rites led to the erection—when the bodies could not be found—of cenotaphs, or honorary tombs, before which due observances were paid; and, besides the monuments of those actually buried in the Abbey, are some of this character; and the names of artists not interred here are also kept alive by the association of their works with famous names, in the same way that some people are recorded in the peerage from being allied to daughters of noble houses. Thus the subscription monument to Shakspeare bears prominently on the face of the great poet's pedestal the names of Kent, the architect, who designed, and of Scheemakers, the sculptor, who executed it.

From this rapid glance it will be seen that Barry is treated with a distinction befitting his high excellence; though no notice be made of Chaucer, Milton, and a list of poets, of the warriors by sea and land, the "long lines of noble ancestry" displayed in the tombs of royalty, or the knights and noble dames, whose honored dust comingles in the reverend pile. "Than Westminster Abbey," says Shenstone, "there is no place more suitable to moralise upon the futility of all earthly glory, as there is none which contains the ashes of men that have acquired a greater share of it."

But, though the "storied urn or animated bust" may serve to record the honors paid to the dead by those among whom they lived and moved and had their being, yet it is the momentary gush of feeling poured rapidly out that is the truest reward of high excellence—is most honorable to the departed and most soothing to the bereaved.

To members of the same imperial body it matters little in what part of the British realm a great man first breathed, still it is a circumstance that always attracts curiosity; and now that Sir Charles Barry is gathered to the "illustrious dead," it becomes a thing to note that his birth took place near the scene of the great monument of his genius—the Palace of Parliament at Westminster—though the name would seem to indicate an origin in Erin. Girald Barry, or Giraldus Cambrensis, the author of "Topographia Hibernica" and "Itenerarium Cambriæ," is the first celebrity of the name. Then James, Lord of Santry, Chief Justice of the King's Bench in Ireland; and Barry, the painter, who was born at Cork. Spranger Barry was a man "in person taller than the common size," and an actor of so great a celebrity as to divide the praises of the town with David Garrick a century ago, and to obtain for himself the distinction of interment in Westminster Abbey.

An obituary memoir was delivered at the Institute on Monday evening, the 21st ult., by Mr. Digby Wyatt, in which Barry's professional career was ably traced from its earliest stages to its close.- Mr. Beresford Hope adding, in his usual graceful and thoughtful way, a few words, tending to draw into stricter bonds of amity the followers of one art, and exhorting *Greek* and *Goth* to think of higher warfare and a holier fight than the merely temporary *battle of styles!* On Tuesday, 22nd ult., the Union Jack was displayed half-mast high on the summit of the Victoria Tower, and a sable pennon floated from each of its angle turrets.

The hour of one was appointed for the ceremony, the personal and professional friends of the deceased being invited to assemble previously to that time at the Jerusalem Chamber, of time-honored celebrity. The assemblage was most prompt and numerous; and not only were those who had some mournful duty to fulfil high in the ranks of art and fame, but there were many such among the general mass by whom standing room alone could be obtained. The top of the organ screen, or the rood-loft, as it may be termed, was occupied by many ladies, and others even essayed the dizzy heights of the triforium arches to witness the procession, while

> ". . . Through the long-drawn aisle and fretted vault
> The pealing anthem swelled the note of praise."

The choir could only hold a small proportion of those congregated; but the first part of the service being there performed, the body was again carried through the beautiful screen of decorated Gothic designed by Blore, who preceded Scott, the present architect to the Dean and Chapter. At the length of three full arches to the westward the grave had been hollowed in the sacred earth, and at the close of the impressive service it was crowded round by many anxious for a final look; then came the last heaving booms of the organ, and in silence, as in honor, repose the remains of Sir Charles Barry. Long will it be, however, before his name becomes "to dumb forgetfulness a prey," and the story of his life will, no doubt, be given to the public in a worthy form, whether by Mr. Digby Wyatt or the deceased's son, the Rev. Alfred Barry, of Leeds.

The drawing of the prizes in the Shilling Art Union of Dublin takes place this day.

The Carmelite community of Whitefriar-street have purchased Terenure House with a view of adapting it for the purpose of a noviciate and house of studies.

The Committee No. 1 of the Dublin Corporation have advertised for tenders for a quantity of new sewerage works, to be executed in the city. Time limited to this date, 1st instant.

The corner stone of a Wesleyan Methodist Chapel was laid on the 22nd inst. (by G. F. O'Flaherty, Esq., of Lemonfield) at Oughterard, County Galway. The style, early English. The architect, Mr. Edward Tarleton. The builder, Mr. Geo. Glanville, Ballinasloe.

THE ROMAN CATHOLIC CATHEDRAL, CARLOW.—This handsome edifice has been, we learn from our vigilant contemporary, the *Freeman*, undergoing extensive repairs and decorations under the direction of Messrs. Barff & Co., which have been carried out in a high style of elaborate ornamentation. The chancel is decorated in colours and gold finely wrought out in suitable designs. The ceiling is tinted a light azure, with appropriate and emblematic ornaments. Over the side altars are two representations painted in encaustic, sixteen feet high each. The one on the Gospel side represents the Saviour in glory, the lower part being occupied with figures of St. Conleith and St. Lazarene. On the epistle side the altar is in honour of the Blessed Virgin, who is represented bearing in her arms the infant Redeemer, the lower part of the picture consisting of figures of St. Bridget and St. Dympana. The vaulted roof of the church is treated in the same manner as the chancel. The walls are highly ornamented to correspond with the rich decorations round the high altar and sanctuary. The transept ceilings are decorated so as to harmonize with the other embellishments of the sacred edifice. The four new stained glass windows in the chancel contain figures of angels bearing the instruments of the Passion. A new organ, by Bevington & Sons, of London, containing 1506 pipes, and of great compass, has also been added.

THE BOOK CLUB.—We were peripatetic, and moved the scene from house to house. We arrived with punctuality, and coffee was served at eight o'clock. After imbibing that not inebriating beverage, and exchanging its concomitant little courtesies, the host for the evening was called to the chair, supported on either hand by the treasurer and secretary. The business then began in the correct and formal manner by a perusal of the minutes; and although it may be thought that the record must necessarily have been of a most simple kind, the discussion was just as animated as though it had taken place in a large assembly. The cornucopia of literature was emptied on the table, and a bouquet selected for the coming month. The works of theologians were freely admitted, but theological subjects—never! General topics after this, with a libation, as modest in quantity as though we had been Epizephrii, but of rare and curious age and quality, usually detained us till the eleventh hour. A two guinea subscription covered the purchase and circulation of books, and the fund was augmented by the produce of the last year's works, which were sold to the members after dinner, at our anniversary meeting—an expensive way of doing the business, but it was our only festival. While a member of that little republic, I noticed that although the books sold for half their average cost, and the current subscription was annually augmented in this ratio, it never doubled itself. According to this view a subscription of £20, augmented by ten for old books, would make £30 at the commencement of the second year, half thirty, added to twenty, would be thirty-five for the third year, and so on; but when, let me ask the mathematician, would it arrive at £40? The property of that singular curve which always approaches a given point, but never reaches it, seems here brought into practical application.—*Morris' House for the Suburbs.*

SCIENCE FOR THE PEOPLE.

"There is a spot of earth supremely blest,
A dearer, sweeter spot than all the rest,
Where man, creation's tyrant, casts aside
His sword and sceptre, pageantry and pride,
While in his softened looks benignly blend
The sire, the son, the husband, brother, friend;
Here woman reigns: the mother, daughter, wife,
Strew with fresh flowers the narrow way of life!
In the clear heaven of her delightful eye,
An angel-guard of loves and graces lie;
Around her knees domestic duties meet,
And fireside pleasures gambol at her feet:
Where shall that land, that spot of earth be found?
Art thou a man?—a patriot?—look around;
O, thou shalt find, howe'er thy footsteps roam,
That land thy country, and that spot thy home!"

THUS does the pleasant, bold, and vigorous pen of James Montgomery direct our thoughts to the blessings around us, and our reply is, that we are ever ready so to turn them. "We love the land we live in," and are filial, fraternal, and fatherly—patriotic, connubial and domestic. Nor these in a light or formal way, but seriously, earnestly, rationally, and deeply!

So far so good, and in proportion to our regard will be an anxiety to adopt every means of increasing the health and happiness of all those who in any way appertain to us, and the general welfare. It seems a very proper course, then, to impart to every individual the power of discerning the principles on which his own good, in a natural point of view, is dependent—a branch of knowledge termed SOCIAL SCIENCE. It takes a wide and comprehensive scope, and admits of universal application.

We cannot but look with interest, therefore, to sanitary enactments, to the proceedings of boards of health, to the growing attention of public cleanliness and propriety, indoor comfort, and health-securing observances. We notice with good will the exhortations of writers and the facilities afforded by inventors and manufacturers, who have already brought many appliances into use, and which our physicians, architects, and scientific men are labouring daily to increase and improve.

To such efforts we shall no doubt have to ascribe, among the results of the next census, an advanced longevity in various ranks and classes, and a corresponding diminution in the fevers and other diseases consequent upon imperfect drainage, insufficient ventilation, impure water, and such like contingencies. The subjects which bear upon these and similar considerations are now grouped, as we have already said, under the designation of Social Science, and are attracting a large share of public attention.

Mr. Morris, in "A House in the Suburbs," has pointed to the danger of internal water-closets, which, when unsupplied, "admit into our dwellings gases of the most poisonous character, fraught with fevers, cholera, death! while the cause is perhaps unsuspected. I used," he says, "to visit a family, who resided in an old house at Islington. The smell from the drains was intolerable to strangers, though not noticed by the inmates, all of whom had, however, most indifferent health, and the doctor was seldom absent. I built a house for them afterwards, at a short distance from town, and their health has improved in so marked a degree, that medicine is almost unheard of. Now, the foul air from the drains escapes unchecked into every house the moment the closet is without water!" Attention to soil and waste pipes cannot indeed be too strongly insisted upon.

Wherever a drain communicates with the atmosphere of a house, the architect carefully provides traps to prevent the passage of unwholesome odours, yet how commonly do we find these very precautions rendered inoperative by the negligence of servants and the want of perception in their superiors. The subject is now well rooted in the minds of certain pioneers, and an association of schoolmasters has been formed, with a view to introduce into school teaching the elements of economical and sanitary knowledge, the advantages derived from mechanical inventions, &c. A class has been opened at University College, London, and Lord Brougham presided at the recent inaugural meeting. The effort is entitled to our best wishes, as such a feature in the education of the industrial, as well as higher ranks, must prove of great advantage to the community; and although the sons of Erin may be running abreast of their London brethren in the race of intelligence, the curling waves and sharp breakers of the Irish Sea are still between them, and the exchange of notes cannot be too frequent and reciprocal.

THE FOSSILIFEROUS GREYWACKE ROCKS OF IRELAND.

AT a recent general meeting of the Geological Society, held in the Museum building, T.C.D., Mr. Kelly read a paper on this subject, of which the following is the substance :—

"He said that this greywacke of Ireland was by no means easily recognised in its subdivisions. The general grey colour was very constant in the north, in both slates and grits. In the south the grits were mostly greenish or brown, the slates were green, grey, red, or purple. All those varieties of both kinds were frequently repeated, and the bands mostly narrow. In fact our greywacke rocks had no constant type. The Tyrone district had but few features in common with Galway, the Kildare and Dublin were different from either. Wexford had a resemblance to the unexplored counties of Ulster, but unlike Tyrone, Galway, or Dublin, and the Kerry and Cork district, in the detail of the beds, lithological character, and other particulars was very different from all or any of the other four. The silurian system of Sir Roderick Murchison had been the guide for the identification of zones of superposition in the greywacke rocks for the last 20 years. By that system the world was led to believe that the greywacke formation was made by nature into seven definite fossiliferous zones, founded on superposition, and that each zone contained a peculiar group of fossils. This was a great error. There were no such seven zones to be found in any known natural sequence of those old rocks. The district of country between Colebrook Dale and Ludlow was selected as the model of this system, but that country had only three of the zones. It is a peculiar district, unlike any other, and therefore unfit to be put forward as a model to teach all nations in geology. In Ireland there was nothing like that district physically, although many hundreds of the same fossils occurred up and down in both. In Connemara the fossils occurred in local groups, and neither the species of the fossils, nor the lithological character of the rocks was persistent for any great distance. Were it not for the basal brownstone band, which was an indisputable index in Connemara, a table might be found of seven or eight columns from those local groups. It was found on examination of the table in the silurian system that scores of the fossils which were put into the upper zone there have since been found in lower zones in other parts of Great Britain and Ireland. This spoiled the system. Connemara, where the bottom of the system was clearly visible, would never suggest a division of the greywacke into seven zones. The original silurian district and the Tyrone district appeared to be geological equivalents. The so-called old red sandstone of Hertfordshire overlays the silurian rocks at Ludlow and Aymestry conformably. The brown stone of Tyrone, the same kind of rock, overlays the fossiliferous rocks at Lisbellaw and at Pomeroy. In both cases the brown rocks were from 7,000 to 8,000 feet thick. Putting the Tyrone fossils in the upper part was contrary to all the laws of fossils hitherto made. The table of evidence alluded to showed that scores of the fossils, which were put as upper silurian, had since been found in lower zones. He got at Dudley 52 species. Professor Sedgwick got there 45, but of those 13 were the same as the author got, leaving 32 not found there before. Those added made 84 species, 34 of these were corals or crinoids, which, taken out of the above numbers left 50 species. If those 50 were strictly examined by the new table it would be seen that 49 of them had been found in lower silurian localities in other places. Even leaving in the corals and crinoids, from 84 take 49, left 35 upper silurian fossils. Thus more fossils were found at Dudley belonging to the lower silurian zones than to the upper, and Dudley cannot be called an upper silurian locality. Another locality, called upper silurian, tried by the same test, gave 16 fossils found in lower silurian zones, and three exclusively upper. With the majority of the fossils this locality must be called lower silurian. At Benson Knot, in Westmoreland, Professor Sedgwick got 50 species. He gave a list of them at p. 352, of the Brit. Pal. Fos. Of these 15 were new, so that he found 34 species known before. Trying this list by the same test as before, it turned out that 31 species had been found in lower zones in other places, leaving only three species upper. In the original silurian country, lying between Coalbrook Dale and Aymestry, 20 miles long and four miles wide, there were found 122 pieces. Testing this truly upper silurian area, the model farm of the silurian system, as it might be called, as before, the result was 82 fossils belonging to lower silurian zones and 40 upper. This also, with the majority of the fossils, must be called a lower silurian district. This extraordinary result could not have been foreseen by the author when he published the silurian system, it had been developed by discoveries and publications made since that time. From the above results, it would be seen that that system must fall to the ground."

The idea of erecting a statue to Gerald Griffin, the author of "The Collegians," is being agitated in Limerick.

Is is sought to place the town of Balbriggan under the Towns Improvement Act.

TURN OFF YOUR GAS.—A boy has been killed at Exeter by sleeping in a room in which the gas had been imperfectly turned off by his mother.

ON ANCIENT MASON-MARKS AT YOUGHAL AND ELSEWHERE; AND THE SECRET LANGUAGE OF THE CRAFTSMEN OF THE MIDDLE AGES IN IRELAND.

Mr. Edward Fitzgerald, Architect, Youghal, in an excellent paper, read before the Kilkenny Architectural, &c., Society, communicated the following .—

The Rev. James Graves has discovered some very interesting specimens in the Cathedral of St. Canice, Kilkenny, and Dunbrody Abbey, on works of about A.D. 1250; the same marks occur in both buildings to a certain extent, and two from St. Canice are identical with two marks from the Cathedral of Presburg, published on the plate to my former paper, being the two last but one on the plate. Mr. W. Gillespie, Architect, Cork, mentions the discovery of some on the ancient parish church of Drumcliff, county of Cork; they consisted chiefly of the favourite emblem in masonry, the square, and were often repeated through the building. In a note from Archdeacon Rowan, he says—"You will find some worthy your attention in Holy Cross Abbey, where I saw them a few years ago, in a hasty visit made between two trains from the adjacent railway station. I had not time to copy them, and I dare say there are a great many more than I noticed in a cursory inspection, especially on the interior north wall of the nave."

The Rev. John W. Hopkin also, in a note, mentions the discovery of some on the south transept of the old church of Kinsale; they chiefly consist of varieties of one of the marks found at Youghal, which were published with the former paper.

On a semi-Norman arch in the ruined Cathedral at Ardmore, I discovered one mark very similar to a specimen given in Mr. Chalmers' Plate, in the "Archæologia," which was taken from the ancient hospital at Brechin.

At a comparative late period, it would appear that others beside the building operatives used mason-marks on their handiworks, as we find them on cooking and other utensils, showing that a fraternity existed in which *they* were included. On an ancient bronze three-legged pot, which was found in an Irish bog, and now deposited in the Museum of the "Royal Cork Institution," are some interesting mason-marks. This old culinary utensil is no bad specimen of the sixteenth century casting. The exterior is divided into ornamental compartments by radiating raised lines, two of the compartments being ornamented with mason-marks, and the Roman numerals, DMI, which I am inclined to consider is the date 1501. The marks represent interlaced triangles and a heart, similar to the marks taken from St. Ninian's Lodge-books, Brechin, figured on the plate to my former paper. In the second volume of the *Dublin Penny Journal*, at page 249, an interesting woodcut is given of an ancient drinking vessel—the old Irish mether—on the surface of which is carved several mason-marks, and among them the owner's name forms a conspicuous object, DERMO + TULLY, 1590. Dermo, it would seem, was a thirsty old soul, from the value he seems to have set on his old wooden wine vessels, and there can be little doubt that he was a free-and-easy member of the mystic fraternity.

In the former paper on this subject, an inference was drawn from the remarkable fact that the Irish mason-marks, already discovered, exactly coincided with those copied from ancient British and Continental buildings, and the conclusion come to, that instead of the early Irish being indebted to English and Continental architects and artists for their architecture and arts—so generally asserted by superficial writers—we have the strongest reasons to conclude that they were the debtors to the early Irish; and not only for their architecture and arts, but also for their religion and literature, as the following gleanings from numerous sources will amply prove—all-important facts, tending to show the close connexion which existed in the early ages of Christianity between the Irish, British, and Continental Churches.

The learned Dr. Prideaux, speaking of Ireland during the early ages, mentions it "as the emporium and prime seat of sacred learning in Christendom." Dr. Johnson also mentions the "times when Ireland was the school of the west, the quiet habitation of sanctity and literature." In Guizot's "History of Civilization" we read—"Of all the western countries, Ireland was that wherein letters maintained themselves and prospered, amidst the general confusion of Europe." And lastly, from a host of evidence of similar import, I select a word from St. Bernard, where he says—"From Ireland, as from an overflowing stream, crowds of holy men descended on foreign nations."

In the "Ordnance Survey of the Parish of Templemore." p. 230, the writer (believed to be Dr. Petrie), speaking on the Grianan of Aileach, places the masonic dialect or Barelogirnasair much higher in the scale of antiquities than I have done. He says:—

"The ruined fort of Aileach presents an example of barbaric art, not imitative of the refinement of the Egyptians, the Greeks, or the Romans, but of that ruder and more distant effort at civilization, belonging to the heroic ages, of which so many vestiges have been recently found in various countries; an example of the architecture of that race who have left so many other evidences of their existence in Ireland, as to their religion, their language, called the *Masonic dialect*, and composed of Semitic words, and the Punic or early Greek-shaped swords and other antiquities of bronze, silver, and gold, so constantly discovered in the country. In the general characteristic of this ancient work the antiquary will at once recognise the features of the first efforts in architectural art, 'les ouvrages *d'un art sans art*,' as they have been fancifully called, which, whether ascribed to the Titans, Cyclopeans, Pelasgians, or 'Wandering Architects,' are found to pervade so extensive a portion of the old world."

OBITUARY.

SIR CHARLES BARRY, R.A., ARCHITECT.

THOUGH anticipated by our brother journalists to the extent of a fortnight or so in the chronicling of this sad and unexpected event, we must not—even though hazarding censure for repetition—refrain from adding one quota *in memoriam* of the great architect of universal fame yet modest worth that has passed from this breathing world to, we hope, a better. He too, like his illustrious brethren in the engineering world, Brunel and Stephenson, was summoned to eternity before his professional mission was accomplished, and though he lived to see the main features and "the cloud-capped towers" of his noble work, the Westminster Palace, realized, yet "death tolled his knell" before the infant offspring of his genius was fully matured. The national loss thereby sustained will, we trust, be mitigated to an extent by the judicious appointment of a successor. Sir Charles Barry was born on the 23rd of May, 1795, in Bridge-street, Westminster, the scene of his future great triumph, and was articled to Messrs. Midleton and Bailey, surveyors to the parish of Lambeth; and died on the 12th ult., after a few moments illness, of disease of the heart and lungs. There appears to be a supposition that Sir Charles Barry was a Corkonian, in which, however, as we learn, there is no truth whatever; though the frequent occurrence of the name in that county may present a possibility of some of his relatives being natives thereof. Sir Charles's chief works, in addition to that before alluded to, were the Earl of Ellesmere's house—perhaps his *chef d'œuvre*—the Traveller's Club, Reform Club, the Manchester Athenæum, and various palatial residences throughout England. In Italian as well as Gothic architecture the late professor was pre-eminent—indeed his works in the former style somewhat supersede in excellence the latter, and he may with all truth be adjudged the palm therein, before his fellows in any quarter of the globe. We are not aware that Sir Charles's practice at any time extended to this country. On the 11th February, 1852, after the new House of Commons was opened, her Majesty conferred the honour of knighthood on the then Mr. Barry; but it must be regretted that that perishable title was not afterwards supplanted by one assignable to perpetuity. His remains were interred in Westminster Abbey on the 22nd ult., in presence of an artistic constellation—an honour to which both the country and the profession will bear grateful recognition.[*] It is enough to add that Sir Charles's genius did not—like that of many, "whose light is hid under a bushel"—pass unrequited, for he has left outside the tomb—and perpetuated in substantial monuments of his skill, for posterity "to admire and be instructed"—a name immortal as his great predecessor, Sir Christopher Wren, and, despite his treatment by Government in the £ s. d. matter of fees for the Palace, has left a handsome fortune to his family.

Mr. Thomas Hughes, a respected fellow-citizen, and for a large number of years proprietor of the Oxmantown Foundry, North King-street (now in possession of Mr. William Turner), expired on the 14th ult., at the advanced age of 72. He had executed some important contracts in iron castings during his lifetime; amongst the ornamental of which, we may name the railings of the Four Courts. Viceregal Lodge, &c.

The organ of St. Patrick's Cathedral—which, doubtless, our readers are aware, was taken from the Spanish Armada—has had new stops added thereto by Messrs. Bevington, of London, at a cost of £200.

Mr. Frederick S. Barff is to deliver a lecture at the Dublin Mechanics' Institute on "Decorative Art."

Mr. Foley has completed his statue of Caractacus, which will immediately be placed at the Mansion House, London. The artist has also received the commission to execute a statue of Goldsmith, to be placed in Trinity College, Dublin.

KERFS AND COGITATIONS.

BY A CRAFTSMAN.

NO. III.—ARCHITECTURAL FUNGI.

IN the midst of a building mania, now almost chronic in its duration, one seeks for something of progression in architectural taste, and constructive ability; but, alas, little truly worthy in name as regards correct classical taste, combination, or chaste ornamentation in detail are to be met with. Ability we have; innumerable are the pens and pencils employed in our service, competition is rife, and contract rebellious; but we lack the Spartan rigidity of principle, the fixity of purpose, the moral code of honour, the self-denial and disinterestedness the manly spirit, and the manly act, and the many other *traits*, which go to distinguish the man amongst men before studious perseverance and acquirements make him a prominent worker of the world. Archimedes is reported to have said—"Give me a proper position, and a lever, and I'll move the world." But it would take a greater than Archimedes, with all his putative profundity, to raise the antique taste of architecture from the ruin, and rubbish, and cold neglect, which for two-thirds of a century, in this city, has been obscuring it. Architects we've many, capable of better than the "foundlings" that bear their name. and which are continually appealing to them for a parent's protection, but the niggardly spirit of the age often obliges them to strip nude the children of their brain before they can present them to a callous public for adoption; thus the chiselled granite of their imagination often becomes the plastic patchwork of their patrons, and by it, the glowing genius of many a youthful aspirant in marble perishes on the mortar-board of the scaglioli worker. Builders we have, but few indeed of the old school, the claims of the scientific man are ignored—forsooth his estimates are too high, he wishes to carry on his work under the superintendence of an architect—and to escape the never-ending alterations of ever-changing novice, or eccentric over-seeing owner, he usurps no office but his own, he pays his workmen a fair and remunerative rate of wages, and, come what will, he finishes his work in a creditable and workman-like manner. Not so the confirmed botch, turned incipient builder, escaping by some fortuitous help, he chooses 'twixt continued degradation and resuscitated respect, opens "shop," and begins. Quantity not quality becomes the order of the day. Contracts are undertaken at first, not for *paying*, but for popularity; not the popularity of credit, but the notoriety of *consequence*. Matters go on for awhile, work increases, hands are put on, profits *must* ensue now, fortunes *must* be made, and to do all this the toiler must be driven; but all fails, stagnation staggers on, and the *finale* is bankruptcy and ruin. Need we wonder that artizans, under such a system, become mechanical automatas instead of invaluable workmen?

Architecture—practically speaking that which springs through the manipulations of the finger—has certainly degenerated, but its decline is more or less attributable to the contract system, and the low condition which the artificer, by the abuse of that system, was reduced to. The architecture of any age is the surest criterion of its civilisation; but if *some* of ours be judged by *that* standard we shall appear in a pitiable plight before posterity. Let us stroll through our suburban districts and see what a medly of architectural monstrosities present themselves—a conglomerate of all sorts of styles zig-zag meddled together in indescribable confusion, sometimes detached, sometimes twin—like Siamese, and inseparable—Saxon and Saracen, mock Mosiac and Moorish, Oriental and outlandish; all evidences of a morbid and corrupt taste, and distorted design, alien in nature and in name; even the native vocabulary was eschewed for their baptism, and they were accordingly christened after some disembowelled bandit, or Russian redoubt; their access is guarded by some Cerberus, or Centaur of defunct genera—fitting emblems to the imbecile erections they are supposed to adorn. But if the foregoing be taken as a sign of the discriminating task of our people, let us help them out. Up then with inverted consoles and composite cornices! up with mock entablature and sham pilaster,—the reign of vandalism begins; up with baseless shaft and headstone capital! up Peter de la Roche from the grave of the Capulets, age will lack no disciples now. But enough! If the "Modern Master" wishes to excel the grace and perfect proportion of his Pagan prototype, let him try, but let him not mutilate and disfigure what his little knowledge may citicise, but which it can never create. Oh, art-student and artist-craftsman, would you take a lesson from one of noble monuments of your own, pass out with me into that old hallowed "green" on one of the mellow midnights of this moonlight May! Come out too, *ye dilletanti* of our squares, and *ye* pale enthusiasts of our liberties, if the iron has not entered your soul, you will see something worthy of admiration in that grand old pile before you! Alas, no sculptural Titan of Ireland's past greatness adorns those naked niches—the accumulating *deltas* of time seems incrusting on column and cornice—but age is only shadowing forth in greater relief the undying grandeur of Corinthian capital and Ionic volute—old haunt of buried hopes and baffled aspirations, fit symbolization without, of the intellectual stature once within! Where are now the souls that quickened, the hearts that leaped, the bosoms that swelled, as fiery tongues with lightning flash, and thunder declamation lit up and reverberated within those walls? Gone! all gone! Speaker's chair and strangers gallery are vacant now! Mammon alone sits here in council supreme, and close by, bartering Jew and gabbering Gentile beat time to that never wearying accompaniment on "change;" but let's home! on out, under piazza, and round underneath portico. Behold where the corruscation of Gandon's genius left an everlasting frontispiece for succeeding generations to admire and copy! While works like these are amongst us, we can never grow poor or disheartened—they will act as incentives for emulation and study, and under their shade some youthful aspirant may yet take courage. Sooner or later some great architect will arise, trampling down the trammels of his time, soar to heaven with the conceptions of a soul sublime for the ennobling of an art that has outlasted the wreck and ruin of empires, somnolent systems, and degenerated species.

C. C. H —y.

LAW NOTES.

WE learn that the case of *Kempston* v. *Butler*, fully reported in our Nos. for March and April, and upon which the jury disagreed, will again come on this (Trinity) Term. It appears to be a matter greatly to be regretted, after the lengthened and expensive contest that has passed, eventuating in nothing, and the scales so evenly divided for plaintiff and defendant that an amicable adjustment is not being come to even at a sacrifice to either party rather than again risking "the hazard of the die."

Hugh Kelly v. *John G. Smyley*.—Action brought by plaintiff to recover from the executor of the late Sir Philip Crampton £663 for extra work and labour. The amount of the original contract (£2,000) was paid. The plaintiff stated he had a series of interviews with the late Sir Philip Crampton, relative to the construction of a house at Violet-hill, county Fermanagh, for his son, the Rev. Josiah Crampton; in the course of which, Sir Philip desired him to make any alterations in the building which the Rev. Josiah Crampton wished. The house was intended for his (Josiah's) benefit, and therefore he was the best judge as to what was requisite. There were several conversations between them about the progress of the work and the requisite changes and improvements; and Sir Philip invariably said that he (plaintiff) should make any alteration which the Rev. Josiah Crampton desired. He saw Sir Philip upon four or five occasions, and received four instalments. The plaintiff was cross-examined at much length. Sir Philip said, that he ought to make any alterations that his son suggested, and he thought Sir Philip added, "any alterations directed by the architect." He might have the sanction of either, and was to do whatever his son or the architect desired.

Mr. Sergeant Fitzgibbon for the defence said—In reference to the evidence of the plaintiff relative to his alleged conversation with the deceased baronet, that assuming his version of the conversation to be accurate, Sir Philip merely intended that the plaintiff should follow the written orders of the Rev. Josiah Crampton, or the written orders of the architect, approving of the recommendations or suggestions of the Rev. Josiah Crampton; but in any case written orders were necessary, which had not been given.

The jury, at an advanced hour, came into Court with a verdict for £300 for plaintiff over and above the £100 lodged in Court.

Messrs. Rollestone, Q.C., and Armstrong, Q.C., and Mr. Coffey, were counsel for the plaintiff, with Mr. Tinkler as attorney; Sergeant Fitzgibbon, Q.C., Messrs. Chatterton, Q.C., and Levinge, for the defendant, with Mr. Franks as attorney.

Relative to the same matter a counter-action is on the *tapis*.

Smyley v. *Kelly*.—Mr. Coffey for the defendant, applied for liberty to plead double matter. The action is for alleged breach of contract, entered into with the late Sir P. Crampton, to build a glebe-house near Enniskillen, and in reference to which the defendant lately obtained a verdict against the present plaintiff. It was sought to plead that the work was done in accordance with the plans and specifications, and that the work done and the materials used were not of the description alleged in the summons and plaint.

Application granted.

Harford v. Right Honble. Sydney Herbert, Secretary at War.—This action is being brought by Mr. Hans Harford, of Green-street, builder, for £530, for works done upon a chapel school at the Curragh Camp, and liberty was granted by the Court of Exchequer to substitute service upon William Roche, Esq., Solicitor, Colonel Frome, R.E., and Captain Synge, R.E.

Correspondence.

THE GEORGE'S DOCK BRIDGE.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR,—May I beg the favour of your publishing the following letter, originally addressed to the *Freeman's Journal*—but for some seemingly unaccountable reason not inserted therein—as a reply to some of my anonymous friends, who, I believe, think it fair sport to hunt a man to death—particularly if he be Irish, and attempt anything new—but who "little know the ills that envelop him that meddles with cold iron."—I am, Sir, your obedient servant,

M. KENNY.

TO THE EDITOR OF THE FREEMAN'S JOURNAL.

SIR,—In justice I hope you will publish the following in reply to the continuous attacks made in your commercial notice against the George's Dock Bridge, of which I am the patentee. The last article is so insulting, injurious, and untrue, without the slightest pretext or foundation, that I must individually, in self-defence, protest against its continuance; for a better, sounder, or more substantial work of the kind has never been executed, and I defy the writer to point out any single portion of the principle of workmanship to which his choice language is applicable. The only argument I need offer in favour of the design is its subsequent adoption in four instances by the leading engineers of the day. The calculated speed of the bridge has been exceeded by two minutes—not a very grievous error in so large a piece of work, and the first of the kind executed. The other portion of the writer's information is so preposterous as not to need a reply. I may add, that it is rather discouraging and dangerous to attempt anything national or new, if one is to be subjected to the ordeal of the continual annoyance consequent on the evidently limited information of any gentleman having the ear of the public through your popular and valuable paper.—I am, sir, your obedient servant, M. KENNY.

THE EXCURSION SEASON—RECREATION AND IMPROVEMENT.

SIR,—That enterprise which always characterizes our English neighbours, both in matters of business and pleasure, is prominent even at this early period of the season in their excursion arrangements for the million. Many coloured bills, scattered everywhere, and feet—not inches—of the advertising columns of newspapers announce a complete system of "cheap trips", commencing with the Whitsuntide holidays—for example, per two trunk lines from Manchester, Liverpool, &c., to London and back, allowing three days to visit the metropolis, for 12s. 6d.! and *vice versa;* again from Manchester and Liverpool to Dublin and back for 8s. 6d!—to Belfast and back, or to Isle of Man and back for 8s.! besides innumerable others proportionately cheap. Now is it not a strange fact that our City of Dublin or Liverpool Steam Packet Companies display no desire to reciprocate these trips, and, by a mutual understanding, give the Irish public the benefit of such facilities to recreate and improve themselves by a short visit to the manufacturing districts and metropolis of England—should I not say the world? To meet the trips alluded to, the cabin fare from Dublin to Liverpool is alone 12s. 6d.! and *another* 12s. 6d. back!—viz., *double* the amount of a return excursion ticket from that town to London, and *treble* the sum for which a Manchester excursionist may visit Dublin, Belfast, or the Isle of Man, and return home. Is not this deficiency worthy the consideration of a Marcus, a Cole, or a Stanley, the enterprising conductors of various excursion systems? May not the London and North-Western and Great Northern Railway Companies—both of whom now hold constant communication with this metropolis—be convinced of the desirability to extend their speculative arrangements to Ireland, and on a clearer principle than that adopted some years since by the former company?

AN ARTIZAN.

CITY NUISANCES.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR—Your vigilant exposition of "municipal improvements," and various sanitary abuses demanding reform, suggests to me to seek aid—denied me by a morning cotemporary—from *you*, towards the suppression of what may well be characterised a "public nuisance." In your and other columns the popular phrase "dear dirty Dublin" is sometimes quoted, and though an Irishman to the back-bone, I must admit that there is much truth in it. In the slums of the Liberty, the Poddle, and other classic (?) localities, it may not be a matter of *much* wonder that filth and indecency find some countenance; but in a leading thoroughfare, the high road to the most important of our southern coast suburbs, and to the terminus of our most prosperous and fashionably patronized line—the Kingstown branch—that the evil I allude to *should exist unheeded,* "shocks all common sense." Compared with other cities and towns of even less magnitude, Dublin is fearfully deficient in structural provisions for necessity, and the substitutes therefor found in her lanes and alleys, are positive outrages on decency. To *one specially* of these I would now direct your attention, and when I particularize it as the notorious Spring Garden-lane, leading from Great Brunswick-street to Townsend-street, and intersecting the former at Giblan's, the stucco plasterers, and Clarke's the upholsterer's respectively, I trust you will not deem my occupancy of your space an uncalled-for intrusion. Surely something might be done, if not totally to suppress, at least to mitigate, this nuisance? May I, Mr. Editor, ask your opinion?

A HOUSEHOLDER.

[Being a public thoroughfare, it cannot be interfered with without the consent of the Corporation; to obtain which, a requisition would be the proper course. Assuming assent to be granted, we have no doubt that the parties locally interested would, by subscription, defray the expense of a pair of gates, a duplicate key to be held by each party having now a right of passage.—ED.]

THE APPOINTMENT AT THE ECCLESIASTICAL COMMISSIONERS BOARD.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR,—In the leader of your May number, entitled "Appointments and *dis*-appointments," you say, with reference to the above matter: "Whatever the result may be, clamour infallibly will arise, not amongst the professional competitors whose abilities might entitle them to the office—for gentlemen would contemn the course—but with those garrulous, useless, busy-bodies, who meddle and talk and write for the sake of notoriety, without one particle of sincere feeling of interest in the issue." Probably, on principle, you *may* be right, and I think you *are;* but, as there is no general rule without an exception, I must, though having some claims to the appellation of a "gentleman," take respectful exception, without being "clamorous," to the course pursued towards the profession by the Commissioners—not, mind you, to their *act* in making the appointment in question, but to the *course.* In your and other journals advertisements issued from the Board soliciting candidates for the vacancy in the architectural department, requiring testimonials, &c. Quite an *emeute* amongst those members of our worthy fraternity who are not burthened with the good things of this life followed the announcement, and every credential that could be hunted up was speedily deposited in the "sanctum sanctorum," 24 Upper Merrion-street, while, all aghast, the owners awaited their honours' "ultimatum." In suspense protracted and dire, consequent on various adjournments, were the candidates detained, until lo! the startling announcement at length was made, that the Board had selected Mr. Gillespie and Mr. Welland—the son of the late architect—two of their own *employées*—conjointly to fill the office. Now, sir, I abstain from personalities to either of these gentlemen—though one of them was most insultingly assailed in the morning journals—assuming, for aught I know, that they are both perfectly qualified to fill the office, and certainly convinced that the latter gentleman had more than an ordinary claim to a preference from the Board. But, quoting your words, though I am not "garrulous," nor "useless," nor a "busy-body," I nevertheless feel myself justified in proclaiming that such a result could not have arisen from an *impartial* consideration of *all* the candidates' claims, and, therefore, the form gone through was a mere mockery, giving much useless trouble, and causing much chagrin to each professional who, like me,

SOUGHT FOR THE APPOINTMENT.

REPAIRING RAILROAD IRON.—The Great Western Canadian Railway Company has introduced a new system of repairing damaged and worn-out railroad iron in its shops at Hamilton. The mode of accomplishing this is simple, and it is said to be successful. The Hamilton *Spectator* describes the process somewhat as follows:—"A rail which is damaged at the end by the peeling off of a portion of it, or the spreading consequent on hard wood, can have a new piece put in in a very short time, and that, too, in such a manner that the rail is better, and will stand more wear and tear than when new. The rail is heated to a white heat, and a piece of common bar iron welded into the damaged spot, and the rail is as good as new. This operation may be performed to a greater or less extent, as the case may be; some of the rails we saw would require only one foot of new iron, while others would require as much as seven feet. The great advantage of this system over re-rolling is its cheapness. Messrs. Dunning and Wormley, the conductors of this work, say that they can repair these rails at a cost of 6 dollars per ton; while to re-roll them would cost 30 dollars, besides the expense of transportation and duties, if they were done in the United States.

Notes of New Works.

The Mining Company of Ireland are about having twenty cottages erected at Knockmahon; also additions made to the Manager's house, according to plans by Mr. Charles Tarrant, C.E.

The churches of Donacloney (Waringstown) and Drumgooland, county Down, are to be enlarged according to plans, &c., by the Ecclesiastical Commissioners' architects.

A new Roman Catholic church is to be built at Crosspatrick, county Wicklow, for which tenders were received up to 1st inst.

The dwelling-house of Anthony Fox, Esq., of Glenageary, near Kingstown, is being improved under direction of Mr. Caldbeck, architect. Additions were also made thereto recently.

The church of Narraghmore, county Kildare, is to be rebuilt. The rector states that the present roof—flat, ill-constructed, and ceiled—the present windows—wretchedly mean, ill-proportioned, and crooked—the present plastering—uneven, patched, and whitewashed—the present floor—of rough, cracked, and mis-shapen flags—must all be removed; in short, he is about to carry out the designs of the architect for a church more worthy of its holy object and name, including a nave, chancel, and vestry (the two latter are already built) also a porch and spirelet, at a proposed expenditure of about £500. The style is early gothic, and the architect Mr. B. J. Withers.

The new Roman Catholic Church at Raheny is progressing after designs by Mr. Patrick Byrne, architect. It is situated on an elevated mound opposite the church, and at the intersection of two main roads. Interiorly it will comprise a nave 60 feet by 28 feet, and choir 28 feet by 23 feet, sacristy, porches, &c., and display a great chancel arch, traceried east triplet, and west four light windows, five lancets at either sides, and open timber roof, stained and varnished, rising from ornamental stone corbels.

The solemn dedication of the new cathedral at Enniscorthy took place on the 20th ult.

The chapel school at Newbridge, county of Kildare, is to be completed. Tenders till 4th June.

A villa is to be built at Clontarf according to plans by Mr. Joseph Maguire, architect. It is much to be regretted that building works are not more numerous in this locality.

The new church at Newtowncunningham is stated by a correspondent of the *Derry Journal* to have all the advantages of a fine site, being situated on the right hand side of the road leading from Derry to Letterkenny, near the shores of Lough Swilly, and in the midst of a beautiful and picturesque country; and within a short distance of it are the very interesting ruins of the old churches of Belleban and Killyodonnell, overhanging the glassy surface of Lough Swilly. It is built on the site of the old chapel, the foundation stone of which was laid in 1810. After a short time the old chapel became entirely inadequate for the wants of the congregation. The new church is built in the mediæval style of architecture (from a design by Mr. E. W. Godwin, architect), with high pitched roof, &c., and comprises nave, chancel, porch, and sacristy, with bell tower over chancel arch, terminating in a cross. There is also provision made for a transept on the north side, which shall soon be added. The chancel is apsidal and semicircular, and is lighted by three windows, each of one compartment, trefoliated, all filled in with stained glass in rich colours. The central light contains a full length figure of "the Redeemer carrying the Cross," in ruby and purple colours, over which is a canopy, on a blue ground, of passion flowers. The windows on either side are also of stained glass, and contain emblematical devices. In the west gable is a quatrefoil window, the spandrils of which are pierced with geometric forms, and filled in with richly-decorated glass, surrounded by a vine branch and clusters of the rich fruit of fair Italy. The traceried windows in the nave, each of two lights, are made up of tinted cathedral glass, with stained borders, with monograms and flowers in the tracery. The stained glass has been supplied from the studio of the Messrs. Barff and Co., Dublin.

The house No. 39, Westmoreland-street is now undergoing alterations and improvements prior to occupancy by the proprietor, Mr. Austin, of St. Andrew-street.

An effort will be made at no very distant period to carry forward the project of making a railway from Waterford to Fermoy.

The contract for the entire completion of the Newry and Armagh Railway has been taken by Messrs. Wm. M'Cormick, M.P., Green, and King. The works will be completed in eighteen months from the present time, and delivered up to the company, with the rails laid, stations built, and everything in complete working order.

The directors of the Ulster Railway Company have accepted the tender of the Messrs. Edwards for constructing the line of railway from Monaghan to Clones, for which Sir John Macneil is the engineer. The works will be commenced at once, and will be completed by autumn, 1861.

Reviews.

The Poet Shoemaker. By John Carroll. Dublin: John F. Fowler. 3 Crow-street.

"MODEST merit in the shade" is fully exemplified in this little work, and though only dropped casually into our letter-box with the intimation that "its purchase will be thankfully acknowledged as a support" for one "to fortune and to fame unknown," we volunteer it a notice in our columns. The author, with true nobility, prefaces that "he does not offer his composition to the world as the poetry of learning, but merely as the effusions of a naturally sensitive heart, a poetic, yet not highly cultivated mind," and "pleads the many disadvantages surrounding a poor mechanic, whose only opportunities of courting the muse are a few moments now and then abstracted from incessant toil or needful rest," being a member of that humble confraternity which often before gave proof to the world that the making of boots and shoes is an avocation not altogether deserving of the oft-flung learned approbrium, "*Ne sutor ultra crepidum.*" Our poet, for such we term him, believing him to have no small claim to the appellation, must bear in mind the example of many amongst the working classes who "never saying fail," by the dint of energy and perseverance, rose to eminence and opulence;[*] and be not discouraged because *his* sun has not *yet* peeped from behind the clouds which overshadow him. The poetry throughout, though lacking in some respects prosodaical orthodoxy, nevertheless displays an intuitive taste and a naturally musical ear.

"THE POET'S MISSION.

"INTRODUCTORY POEM TO THE AUTHOR'S VOLUME.

"The man who makes one little flow'r
Bloom where no flow'r had bloom'd before;
Born 'neath some happier planet's power,
What blessings he on earth might pour!
That simple, honest, useful man!
He builds a monument to fame,
Where, though the world may fail to scan,
Heaven reads a worthy hero's name!

"So, in the higher realms of thought,
The humblest Bard that brings to light
One flow'r of soul, divinely taught
To root, and bud, and blossom bright;
That anxious, toiling, tearful Bard!
Though slow the world to recognize,
And hears his name but to discard—
Angels may breathe it in the skies!

"On desert wastes the traveller fails—
Parch'd—fainting 'neath the simoom's wings;
But lo! the camel snuffs the gales
That call him to the isle of springs.
Some thoughful patriarch in his day
Had sunk these pleasant fountains here,
And pilgrims halt upon the way
To gild his memory with a tear.

"Thus, in this wilderness of woe,
The Poet strikes the desert's sands,
And forth sweet springs of comfort flow—
Cool fountains in the barren lands;
And oh! when I shall breathless sleep!
Some weary traveller by the brook
For me a grateful tear may weep,
And love me for this little book."

Photographic Etching. By William Strudwick, 2, Bolton-terrace, Newington, London.

THE object of this little pamphlet is to show how drawings may be copied *ad infinitum*, by a simple but certain photographic process, and without a camera or other expensive apparatus. We have seen some specimens of the process, and to architects, engineers, surveyors, &c., the invention is an incalculable acquisition. Relative to the saving of time effected, we may state that, on a fine day, one person can produce from thirty to forty copies of any drawing; and, if the drawing be simple and worth while to make two originals, separately or on the same plate, of course double the number of copies could be obtained in the same time. We trust that appreciation will be evidenced by extensive demand for possession of the manipulatory secret, which is obtainable from the author as above for *eighteen* postage stamps. Who, for such a paltry consideration, would notbe enlightened?

Kilkenny and South-East of Ireland Archæological Society. Dublin: M'Glashan & Gill.

WE have to acknowledge receipt of Vol. II., part ii., new series, 1859, of the proceedings and transactions of this excellent Society. The contents evidence increased energy and devotion, and are replete with matters of interest to the antiquarian and archæologist.

Engineering Journal.

RAIN AS AN AUXILIARY WATER SUPPLY FOR TOWNS.

SITUATED as Ireland is, with the Atlantic ocean on her west, an almost boundless expanse of sea on the south, everywhere surrounded externally by water, and abounding in internal lakes and rivers, it ceases to be matter of marvel that rainy weather is the "rule" and fair weather "the exception" in an island so placed. To this abundant supply of moisture we are indebted for the verdure which everywhere abounds, and the consequent soubriquet of "The Green Island." The quantity of rain which falls per annum in Ireland varies from 22 to 42 inches in depth. The average of those two extreme quantities being 32 inches, may be safely taken as the average, and is fully verified by meteorological observations. One-third of this rain fall flows into the sea, and might be reckoned on as a source of supply for any purpose. Hence the rain fall in one square mile, if impounded and preserved, would yield about 500,000 gallons daily, or sufficient for the supply of 25,000 persons on an average throughout the year. Now nearly all our large towns in Ireland are built almost on a level with the ocean, and in the neighbourhood of hills towering above them many hundred feet, on whose tops the rain descends unheeded and unrecognised, whilst the inhabitants of the adjacent towns are suffering innumerable inconveniencies from the insufficient and impure water supplied.

We would suggest that it be made compulsory for the builders of any tenements, whether domestic, commercial, or otherwise, in cities and towns, to provide for the preservation of water falling from roofs, and its collection first into cisterns for local use, and thence by an overflow into a special main communication, with a public reservoir or reservoirs of sufficient capacity. By this means much waste might be prevented, and much water of superior quality, now used for inferior out-door and household purposes, find a fitting substitute in the unfiltered dews of heaven.

APPARATUS FOR CONVERTING SALT-WATER INTO FRESH.

THE ingenious invention of Dr. Normandy—so says the *Architects' and Mechanics' Journal*, New York—converts the briny sea-water into clear, sparkling, spring-water. It first purifies it of salt; it then charges it, not only with the common air which all wholesome water contains, but also with those other gases which are far more difficult to compose artificially, and which the tongue instantly recognises and craves from habit; it then cools it down to the temperature of spring-water; and finally extracts from it the foreign oily particles made sensible by the act of distillation, and delivers it sparkling and clear. If our own taste is any criterion, we must say that we never tasted better water, either from the purling spring on the mossy bank, or from the well's deep fountain, than that which flowed from this apparatus; and this water, but a few minutes before, was laving the docks of the East River. The first sensation upon drinking it, is that of surprise at the perfect manner in which the object sought has been obtained. This being the case, the great importance of the invention is at once made manifest.

The apparatus is sometimes placed on deck, in which case the sea-water is forced into it by means of a steam pump, which is connected with it for that purpose; and sometimes it is placed in the hold of a ship, below the water line, when the sea-water flows through it by means of two pipes which pierce the vessel's side, one at a lower and the other at a higher elevation, but both under water, the sea brine entering at the lower pipe, and discharging at the upper one.

Steamships, by using this apparatus, can remove a portion of their water-tanks, and thus make room for 30 tons more cargo—the saving effected paying for the apparatus in one voyage. A number of steamers and sailing vessels have had it for a shorter or longer time in use. It is destined to work a complete revolution in the comforts or discomforts of sea voyages, and shortly no passenger ship will be patronized which does not carry within it this artificial fountain of living waters.

A semaphore signal, stated to be "in point of safety, accuracy, and simplicity, one of the greatest improvements in railway arrangements ever contrived," has been placed at the Mallow Station of the G. S. & W. Railway.

Relative to the new patent balance rolling bridge erected over George's Dock, and of which we gave a drawing in April number, a correspondent writes that "for the opening and closing of the late swivel bridge the public were only detained *four* minutes in addition to the time occupied by the vessel paseing, and that *four* men were sufficient to do the work, whereas that with the new, *eight* men, with strength considerably overtaxed, are employed, and the operation takes *thirty-six* minutes to draw back the bridge partially, and would *ten* minutes more if the entire space were required." [For the patentee's explanation we refer to correspondence to be found in another column.—ED.]

A draw-bridge is about being erected by the Corporation of Drogheda, crossing the River Boyne at Shop-street. The time for receiving tenders is limited to this date.

Messrs. Kitson and Co., of Leeds, have made an eight-wheeled engine for South America. She has around the frame a beautiful hand-railing, mounted with brass, so that the driver can walk round the foot with perfect safety. In front there will be fixed a "cow catcher." The trial of the engine was perfectly satisfactory.

The time for sending in proposals for the erection of a lighthouse tower on the Calf Rock, also dwelling-houses in same locality, is extended to 6th inst.

The bog-water of low countries causes a galvanic action in boilers, where brass and iron come together, in contact with it or the steam; and the effect is, rusting away of the iron.

The remarkable increase in the English railway returns is attracting much attention.

The Carrickfergus and Larne Railway Bill has passed.

The Blarney and Macroom Junction Line, as at present projected, is almost straight between the termini.

The committee have reported the preamble of the Letterkenny Railway Bill proven, but rejected the bill for the Lough Swilly extension.

Lord Redesdale refused a deputation on behalf of the West Cork Railway to assent to a proposal for £100,000, at 5 per cent., on baronial guarantees, in lieu of the £80,000, with guaranteed interest, at 4 per cent.

The Mallow and Fermoy Railway was executed at a cost of about £6,500 per mile, total £110,000; including expenses of bridges, stations, and every adjunct. At present only a single line of rails has been laid down, but provision has been made for a double line at any future period.

The viaduct built to carry the railway over the Carrick glen, a deep valley and stream of the Blackwater, is of hewn limestone, on six solid columns of mason-work, the centre columns being 72 feet high, each arch being 45 feet span and 20 feet in the arch.

The Kilcummer viaduct consists of ten arches of iron framework resting on the same number of columns of solid masonry, built of hewn stone. The length from the first column to the last is 250 yards, and greatest height 72 feet. The iron work which though in reality exceedingly strong and capable of withstanding a load of 300 tons at full speed, appears of singularly light and compact construction, was completed by Mr. Anderson, of Dublin, sub-contractor under Mr. Dargan. The mason-work was executed by Mr. Cunningham, also sub-contractor for Mr. Dargan. The construction of the viaduct occupied nearly a year and a-half. There was great difficulty experienced in getting good foundations, but after great labour and anxiety on the part of the resident engineers, Messrs. Dillon and Cotton, and the contractors, Mr. Dargan and Mr. Edwards, solid foundations were obtained, and a thick bed of concrete laid under the highest piers which support the fine lattice girders. The total length of the viaduct is about 540 feet.

TURBINE WATER-WHEELS.—During the trial of the model of a turbine wheel on the Jonville principle, 925 pounds were raised 25 feet, by 70¼ cubic feet of water falling 6 feet. This produced a result of nearly 88 per cent., and to this should be added 3 per cent. for friction of the transmitting machinery, making the true value of the wheel 91 per cent. The chief engineer, and the committee of councils, under whose supervision all the experiments were made, say that no country could have produced wheels of greater power of practicability in their results, than those exhibited. The experiments have brought together inventors and machinists from all parts of the United States, and the comparison of the various wheels, under careful tests, will do much to increase the knowledge of the inventors, and add ultimately to the value of their wheels.—*Phil. Ledger*.

WANT OF LIFTING CRANES ON THE QUAYS.—It seems that there is no crane upon our quays capable of lifting more than five tons, though there is a fifteen ton crane in the Custom-house Docks, and owing to this want Messrs. Cook & Co., of Glasgow, found a considerable difficulty in landing a rivetting machine to the order of Messrs. Courtney and Stephens, and had to employ a pair of shears from the light-house yard, with fifteen men assisting, for that purpose.

Miscellaneous.

LEAD AND PAINT.—A writer in the *Mining Journal*, who has given some calculations, produces very curious results as to the consumption of lead. Taking the export of red and white lead, the chromate of lead for paints and other purposes in the arts, and of litharge for glass making, at 5,000 tons, he proceeds to calculate the yearly waste in connection with the absorption of metals, a subject little investigated, and, so far as building is concerned, of much interest to the trade. He ascertains the home quantity of lead applied for all purposes to be 60,000 tons, being an increase from 30,000 tons in 1825; he estimates that of these 60,000 tons there are worked up for perishable purposes not less than one-half—namely : Paints and glass making, exclusive of export, 20,000 tons ; shot, ditto, 2,000 tons ; paper lead for wrapping, capsules, trade purposes, mechanical uses, chemical works, refining, lotions, pharmaceutical purposes, &c., 8,000—30,000 tons. This is most likely under the mark, for the consumption of lead in the glass manufactures, besides that for glazes, cannot be less than 4,000 tons, leaving only 16,000 tons for paints. The estimate, therefore, cannot be regarded as excessive. The export of white and red lead alone was 5,000 tons in 1857, besides chromate, and quantities employed for engineering and in paints, and further 662 tons of litharge, and the unknown quantity employed in flint and crown glass exported. Taking 30,000 tons as the figure it is estimated that this amount is yearly taken out of the market, leaving not more than 30,000 tons in a metallic shape, such as sheet lead, piping, &c. ; and contribute to the total stock of lead in the market, to be worked up over and over again until consumed. The total value of paint exported cannot be altogether ascertained, but the following are the approximate figures:—Painters' colours (1857) £442,719 ; white and red lead, £140,000 ; ditto unenumerated, £50,000 ; total, say, £630,000.

WARNING TO GAS CONSUMERS.—There is a prejudice against gaslight as being the most injurious form of artificial illumination. There can be little doubt that, from its abuse and bad management, it is really doing more mischief than any other kind of light; its very excellences are turned to bad account; its extreme cheapness, compared with other sources of illumination, naturally leads to its use in excessive quantities: floods of light are poured forth, so that persons may read and sew for hours together in the remotest corners of the room. The air is heated by the excessive combustion, and poisoned by large quantities of carbonic acid, which there are no means of removing. In cold weather shopkeepers shut their doors, so that the gas may warm the place—this, however, is a most dangerous and unhealthy practice, as dangerous as a charcoal stove. When you burn gas take care to have plenty of ventilation.

ROCHESTER, N. Y.—This city contains nearly 50,000 population. It has four English-speaking Catholic Churches, two German, and one French; with convents of the Sacred Heart, Sisters of Mercy, &c., a large hospital, and schools. Two of the churches—St. Patrick's and St. Mary's—are of large dimensions; the latter is a noble edifice, and very handsomely situated, fronting a beautiful park. The church, convent of the Sisters of Mercy, and schools, as projected, will occupy nearly the entire front of the square.

CARBURY CASTLE.—This once noble building is now a complete ruin ; the length of the line of the southern wall is alone 100 feet, and the general view of the castle, with its chimneys, narrow pointed gables, and large stone sashed windows, is one of the best specimens of the castellated mansions of about the time of James I. which we know of in this country, combining lightness, taste, and comfort, with strength and durability. The eastern front, which measures 60 feet, still remains, with several of its mullioned windows even yet quite perfect; and upon a gentle slope leading down from its walls on this side may still be traced the vestiges of a garden with a few of its flowers now wild and neglected mingling with the rank florin grass with which it is surrounded. We perceive from the character of the masonry, the massive walls, the deep, stone-roofed donjons (the principal of which runs for 85 feet underneath the great keep from south to north) the manifest antiquity of the western end, and the general arrangement of the whole, that the present ruin consists of the remains of structures very much older than the early part or middle of the 16th century—indeed some of them would appear to be as old as the twelfth century—and there are remains of walls of great thickness, built with rubble masonry and grouted, extending even beyond the confines of the present ruin to the north-west. The modern additions all exist on the opposite side, and their later date is at once manifest. Four of the chimneys, three of which are in the eastern front, have sixteen sides, and are like some of the chimneys of English castles built about the year 1530, being beautifully wrought and moulded at the top.—*Beauties of the Boyne, by Dr. Wilde.*

INTRAMURAL INTERMENT, ST. PAUL'S PARISH.—On the 8th ult. a meeting of the parishioners was held to denounce and stop the present system of intramural interment. The movement was alleged " to have arisen out of an imaginary cause," and " to injure the rector by depriving him of part of his emoluments." Dr. Madden, a near resident, had no reason to complain of it as a nuisance; Mr. Johnstone deposed similarly; but Mr. Stephens alleged that " the complaint was not any offensiveness of smell, but that in one instance *two* coffins had to be dug up to make room for one to be buried ; that skulls and human bones were at a distance of 18 inches from the surface, and that such had actually been sold at bone-yards in the city." An argument on the illegality of the meeting terminated the proceedings without any result being arrived at ; and very unfortunately, say we, for we believe that on principle the requisitionists are strictly right, and that under any circumstances, intramural interments should not be tolerated.

TO DESTROY WOODLICE.—Place some boiled potatoes, broken in small pieces, into flower-pots, or any other small vessels. Cover the potatoes lightly with some dry moss or hay, and place these where the woodlice are most troublesome ; they will feed upon the potatoes during the night, and finding an agreeable hiding-place beneath the moss will remain there, and can be emptied in the morning into boiling water, and the traps replaced again.

BRITISH DEMAND FOR AMERICAN OAK.—The British Government is drawing largely on the white oak forests of Virginia. Over three hundred men are employed in getting timber in the mountains near Rowlesburgh, on the Cheat River, which is to be used for gun-carriages. The contractor has orders which it will take two years to fill. The Cheat River oak is said to be the best yet imported into England, far surpassing the Canada oak, which it is fast superseding.

BELFAST SCULPTURE—NEW ULSTER BANK.—The top stone has been placed in its position, in the centre of the parapet of this edifice, which is, even under all its disadvantages of situation, by far the most splendid detached building in Belfast. The chastely-classic, yet magnificent, group designed for the crowning ornament of the structure received its principal figure. These highly ornate sculptures, which since their elevation have attracted much attention, consist of, first, an erect and noble figure of Britannia, eleven feet in height. The right hand extends in an easterly direction a wand emblematical at once of imperial sway and mercy; the left is intended to grasp an oar—the rudder of early navigation—symbolical of maritime commerce. Britannia stands upon a massive heraldic shield, two quarterings of which show the arms of Ireland in relief, and the other two those of England and Scotland. The shield is encompassed with a wreath of shamrocks, exquisitely designed and chiselled. The central piece is supported on the right by a recumbent female figure, representing Commerce, as is indicated by the cornucopia, bales of merchandise, and other emblems of abundance and traffic piled in her vicinity. She is delineated as reclining upon a rock, amid verdant and graceful tendrils of the national plant. The figure on the left or western side of Britannia symbolises Justice. As at present seen, Justice is merely armed with her sword, her more appropriate insignia—the scales and nicely-poised beam—having still to be supplied. Whenever it may suit the sculptor to complete the gracious lady's order, it is to be hoped that more respect will be paid to the horizontal line in the beam than that so unaccountably adopted for her prototype on the apex of the County Court-house. "Justice," for a couch has, like St. Kevin, a " flinty rock ;" yet the graceful lines of the figure impart a degree of grace even to her rude resting-place. At the base of the figure are a terrestrial globe, cannon, and other ideal adjuncts of such imagery, whether in stone or on canvas. They, as well as all the rest of the appliances, are admirably executed from the solid block. The measurement of each of the recumbent figures equals that of the Minerva-like statue in the middle—namely, eleven feet as extended. The boldly-defined helmet of Britannia, however, and her commanding position, cause the figure to appear considerably larger than either the others. The entire height of the centre-piece, plinth included, is sixteen feet, and the breadth of the whole group is twenty feet. We learn that the stone used for these sculptures, procured from a highly-prized quarry in Scotland, is excessively difficult to mould to the workman's model, but very durable. After having thus noticed, somewhat in detail, the beautiful ornaments above referred to, we have only further to state that they were executed by our townsman, Mr. Thomas Fitzpatrick, of Wellington-place, to whom also the new Ulster Bank owes whatever it can boast of beauty in the sixteen splendid vase-like ornaments which are scattered about its parapets, and also for the classic heads so generally admired, forming the keystones in the architraves of the principal windows. All the finer sculpture of the building, indeed, we believe, was completed by the same talented artist. He was also the sculptor of the beautifully-massive groups of figures in the tympana of the pediments of the County Court-house and New Custom-house.—*Banner of Ulster.*

THE FINE ARTS.—"THE LIGHT OF THE WORLD."—(Painted by Holmar Hunt.)—When the word "Let there be light" went forth from the lips of God, swift as his thought, light permeated chaos and illuminated the darkness; but time has passed by, year has followed year, and no branch of art has taxed more severely the labour and the patience of the artist than the imitation of light. In our public exhibitions we have had some pictures that surprised and delighted the spectator, but few, if any, challenges the scrutiny of the public more than the picture at present on view in the establishment of Mr. Cranfield, Grafton-street. It may well, indeed, be said that the Arts are handmaids to each other—Poetry suggests the beautiful to Painting, and Painting supplies Sculpture with the features of some beloved one, to which it gives in marble a more permanent existence. Lope de Vega had written some striking lines upon the subject of our Lord waiting, throughout the gloomy nights of winter, outside the shut-up casement of a sinner's soul seeking admission, and the "To-morrow, and to-morrow, and to-morrow creeps on its petty pace from day to day," the casement remains closed. The poet Longfellow has translated these lines, and the painter Hunt has embodied them in a small but effective painting. The picture at first looks like some most highly-finished Japanese or Chinese picture, Pre-Raphaelitic in its every degree; but it is a myth—an allegory—and requires more deep study than the public can generally bestow upon a work of its class to be understood. The lights and shadows are marvellous in their effects, but "one touch of nature" there is not. It is for the hermit in his cell, the nun in her cloister as a study, and not for the busy mass of mankind attractive. How it will engrave it is hard to divine, for the charm of colour for the eye as now present will not be found. This work will have its worshippers in this country, as it has had elsewhere.—*Saunders.*

GRAND JURY PRESENTMENTS FOR THE YEAR 1859.—DUBLIN COUNTY.—New roads, bridges, pipes, gullets, quay walls, hills and hollows and ditches, £1,153; repairs of roads, bridges, pipes, gullets, or walls, £21,053 14s. 10d.; court and sessions houses repairs, £65 8s. 10d.; gaols, &c., building or repairing, £714 5s. Gross amount, £37,543 17s. 2d.

DUBLIN CITY.—Repairs of roads, &c., £300; court of sessions repairs, &c., £194 7s. 9d.; gaols, &c., repairs, &c., £758. Gross amount of presentments, £32,294 6s. 6d.; re-presentments, £3,566 12s. 3d. Net amount, £28,727 14s. 3d.

The total net amount of presentments for all the counties in Ireland is £1,046,409.

STAINING *v.* PAINTING.—There can scarcely be a second opinion that stained and varnished woodwork is in every respect, *when well executed*, superior to painting, however excellent, especially for internal decoration; but we are far from admitting that a couple of coats of clean, plain, ungrained painting is not infinitely preferable to an unsuccessful effort at staining. The latter work must be well done, and the material employed be of the best quality, otherwise it is, like all mere attempts, quite intolerable. Judging from the specimens forwarded to us, with request for special attention, by Mr. F. Swinburn, 22, Bush-lane, Cannon-street, London, we may state, that his fluids and varnish are quite up to the mark of his professions; and the testimonials from eminent architects appended to his prospectus, attest the excellence of his work more forcibly than we are enabled to do practically.

CHROMOTYPOGRAPHY.—M. Rochette has devised a new method of printing the different colours used in this art. Instead of applying a series of plates of stones, each bearing one colour in the usual way, he ranges his plates upon a rotating platform, of smaller dimensions, but like those used on railways. Suppose four plates thus arranged with black, red, blue, and green, and a sheet of four pages, which it is desired to print imposed upon them. One page will be printed in each colour, and by turning the sheet a quarter round each time, the remaining colours will be printed in succession. This apparatus has a mechanical contrivance to ensure accuracy of position; and as the colours admit of super-position, green may be formed by successive printings of yellow and blue, orange by yellow and red, &c.

RAILWAY TRAVELLING ON THE CONTINENT.—Calculations based upon the most authentic returns have established that since the introduction of railways into France there has been only one traveller killed outright in every 2,000,000 of passengers, and there has been only one traveller wounded in every 500,000 passengers. What was the ratio of such casualties in the good old times of slow travelling? Why when the diligences were in use there was on an average of 10 years one killed of every 356,000 travellers by these vehicles, and one wounded in 30,000. It seems, also, that in France, where every care is taken to prevent timid dowagers, nervous *rentiers*, and fast young people getting into danger at stations, the results have been less favourable than in Belgium, where only one has been killed in 9,000,000 of travellers, and one wounded in 2,000,000. Against railway accidents one ought to be able to assure his life and limbs at a very small figure in Germany. In Prussia and the Duchy of Baden there has been but one killed in every 17,500,000 of travellers, and only one wounded in 1,200,000.

THE PALACE OF THE FINE ARTS AT PARIS.—The new buildings of the Palace des Beaux-Arts, on the Quai Malaquais, are advancing rapidly. They are to comprise two large galleries—one on the ground floor, to be specially set apart to the works sent by students at the school at Rome; and the other on the first floor, for the exhibition of the works of pupils of the Ecole des Beaux-Arts. The gallery on the ground floor will be less extensive than the other, as at each end of it space will be reserved for the formation of a small saloon. The entrance to the palace is by a large gateway on the quay. At a later period, a large gallery is to be constructed, somewhat in the style of the Bibliotheque Sainte-Genevie, to unite the Ecole with the new buildings.

THE THEATRES, ETC.

THE THEATRE ROYAL.—Madame Celeste and her Royal Lyceum Company commenced an engagement on the 23rd ultimo, at our National Theatre, and shortly after the extravaganza of "King Thrushbeard" was presented, in which a beautiful transformation scene is the chief attraction. It seems to be a pity that the encouragement afforded to our excellent lessee by theatrical habitués is not sufficient to enable him to keep his establishment open even during a reasonable proportion of the year; and it is doubly a matter of regret, considering the number of his employeés who are thrown out of bread during the intervals. Has public taste declined so much that it is *now* more impracticable than *heretofore* to have a theatrical season? It must be so; for the well-known enterprise of the lessee supplies an affirmative answer! We presume that he yields to the conviction that "an empty house is better than a bad tenant," *ergo*, that it is better to shut up shop altogether than keep open at a *loss*. To the "starring" regimé the fact, however unfortunate, is palpably attributable; for during the first three or four years of Mr. Harris's lesseeship, and while the novelty, contrasting with previous management, of a permanent stock company of excellence in the various branches of histrionic art, tragedy, comedy, opera, burlesque, &c., &c., lasted, did we notice "overflowing houses" during nine months in the year at least, and constant employment afforded to all. But the scene changed, "old favourites" lost their attractions—even Robson, who owes his immensely successful career to his graduation on the Dublin boards, and now A 1 in his peculiar line; T. C. King, admittedly a tragedian and melodramatist of the first order; Henry Haigh, our second English tenor to a certainty; Durand, the barytone, and last, not least, the ladies—Miss Lanza and the Misses Cruise, whose excellence as vocalists is unquestionable; nor even forgetting our old friend, Granby, with his "mustard plaster, sad disaster," his "ma conscience," and "prodigious;" all this combined talent were insufficient to draw a house; and our lessee, yielding with the tide, was compelled to change his tactics and espouse the "starring" system, hitherto prudentially rejected. Hence it is now that none others but a Grisi, a Piccolomini, a Titiens, a Garcia, an Alboni, a Tamberlik, a Mario, a Guiglini, a Sims Reeves, a Graziani, or a Ronconi in Italian opera; a Catherine Hayes, or a Louisa Pyne in English opera; a Charles Kean in tragedy; or a Mathews or a Buckstone in comedy, will serve to keep the coffers of a lessee even reasonably full. And when some one of the constellation is not to be fetched for love or money from their metropolitan engagements, the lessee, feeling that mediocrities *will not pay*, has to close his doors, turn his staff adrift on the chance of their re-assembling, should nothing better turn up, until "the stars," in their annual course, with some speculating deity to guide their movements, pay us a periodical visit. Such is the picture, and for the mutability of public taste we exclaim, "O Tempora, O mores! Tempora mutantur, et nos mutamur ab illis."

HENGLER'S CIRCUS.—This is the most complete establishment of its kind out of London or Paris, and although only a temporary structure, is substantially and tastefully erected, the rostra radiating octagonally with stepped stages from the equestrian circle, and the ventilating arrangements, so necessary in a place of the kind, admirable. The performers are of superior ability, and the appointments and stud such as must command admiration. Much variety is introduced in the bills of fare, and the happy countenances of the audiences proclaim unanimous approbation.

IRISH ACADEMY OF MUSIC.—The Annual Amateur Concert, in aid of the Funds of the Irish Academy of Music, will take place at the Ancient Concert Hall this evening—the Lord Lieutenant has signified his intention of being present. The Concert will consist of an Opera Recital of Bellini's "I Puritani," and a Miscellaneous Selection from the works of eminent composers. The Committee announce that the following distinguished Amateurs are to take part in the performance:—"I Puritani"—Elvira, Lady de Vere; Arturo, Mrs. Edward Geale; Ricardo, Mr. Hercules Macdonnell; Giorgie, Mr. John Stanford; Bruno, Mr. Alan Close. And in the Miscellaneous Selection: Mrs. J. Stanford, Mrs. Joseph Robinson, Colonel Hume, Mr. J. Scott, &c., will assist. Conductor—Mr. Joseph Robinson.

FREEMASONRY PRESENTATION.—At a quarterly meeting of the Provincial Grand Lodge of Munster, held last month, Brother George Chatterton, J.P., Provincial Grand Master of Munster, was presented by Sir John Benson, as Provincial Grand Architect, on behalf of the Mayor, Brother Sir John Arnott, M.P. (unavoidably absent), with a handsome mallet, manufactured by Mr. Hawksworth, having silver head, pure ivory handle, with silver square and compass, in commemoration of the valuable assistance rendered by him and the masonic body at the laying the foundation stone of the new bridge in November last.

CATTLE SHOW BUILDINGS AT CORK.—The plans for these buildings, by Mr. Walker, Architect, C.E., pupil of Sir John Benson, provide for cattle sheds, covering an average of 1,000 lineal feet, horse sheds, do., sheep and pig sheds, implement sheds, 1,300 lineal feet, and 1,000 additional if necessary, a central covered promenade, another at northern side, 330ft. by 81ft. The tender of Messrs. James O'Connor & Son, for the timber, was accepted.

CURIOUS COINCIDENCE.—The four new and powerful steamers in progress for the Atlantic Royal Mail Steam Navigation Company, intended to ply between Galway and America, and those of the City of Dublin Company for the Kingstown and Holyhead route, are, by a singular similarity of thought, christened the same names, viz., Ulster, Munster, Leinster, and Connaught. The words "Province of" attached to those of either company would remove the awkwardness and still serve the purpose.

TO CORRESPONDENTS.

Collenzo, Edinburgh (Your communication is rather *cool* and too palpable *a puff* for our pages, besides being unauthenticated with a name, by which the *competency* of the authority might be judged); W. A., Cork (The same writer in both cases); J. M., Dundalk (In time); C. C. H——y (Please call); Subscriber from the First (Vol. 1 has been bound in wrapper, with index complete, and Vol. 2 will also be separate, with special index, but is paged consecutively, that, if desired, it and Vol. 1 may be permanently bound together); W. T. M., Belfast (Too late).

NOTE.—*Our Subscribers will please to observe that the Journal is (again) enlarged from 24 to 32 pages, irrespective of illustrated supplement, and double the original size, without extra charge.*

BANKRUPT.

Mr. J. H. Carroll, of Upper Dorset-street, formerly of North Frederick-street, Dublin, builder.

TENDERS

For erection of three small houses at Sandymount. John S. Sloane, C.E., architect:—

Mathers	£1220
Laughlin	1120
Pennefather	1055
W. Butler (accepted)	1050

[We are often asked why we do not publish more lists of tenders; the fact is, we cannot obtain them. Architects practising in Ireland seem to be peculiarly churlish on this point, while their brethren elsewhere are only too glad to furnish voluntarily such information. For those, however, as will favour us, we shall be happy to publish them.]

A NEW SQUARE AT RATHGAR.

NEW and very superior Building Sites are now about being laid out and offered to the building public between the top of Kenilworth-square and Roundtown, with approaches from Kenilworth-square, Rathgar-avenue, Garville-avenue, Roundtown-road, and Harold's Cross-road, to be called

KENSINGTON SQUARE.

The collateral roads will be called Kenilworth-avenue, Kensington-road, and Garville-avenue, South.

This property will be sold in Lots in the Landed Estates Court within a couple of months. In meantime proposals will be received for the purchase or letting, without fine, of any portion. Leases for 900 years can be given.

Garnavilla House and Garnavilla Cottage (the latter now vacant) are on this property.

BENTLEY & SON,
110, GRAFTON-STREET, DUBLIN.

IMPORTANT—THE ONLY MANUFACTORY OF OIL-CLOTH IN IRELAND!!!
61 & 62, GREAT STRAND-STREET, DUBLIN,
Entrance, 69, JERVIS-STREET. Established 1791.
JOHN D. FRANKLIN, PROPRIETOR.

J. D. F. invites the Public to see the Floor-cloth making, which cannot be seen in this country unless at his Factory.

HOUSE PAINTING, DECORATING, &c., carried on as usual in the same superior style, with that economy and despatch for which FRANKLIN'S Establishment has been celebrated for the last Sixty Years. J. D. F. begs to inform the Nobility and Gentry that he has been so fortunate as to secure the entire services of two of the first GRAINERS and Ornamental PAINTERS, LETTERERS, &c., in Ireland, and can with confidence undertake the most superior class of work, in addition to the plainest description.

N.B.—A carefully-selected Stock of Room Papers, Decorations, &c., suitable for all description of rooms, at prices not known before. Workmen sent to all parts of the country.

Publications.

A HANDY BOOK on VILLA ARCHITECTURE. By C WICKES, Architect. Five designs, thirty plates, with outline, specifications, and estimates, royal 4to (12½ in. by 10 in.), half morocco, gilt edges, &c., &c. £1 7s.

"An elegant quarto volume. The plans are very well arranged, and the whole may be regarded as decidedly a Handy Book."—*Builder*, October 29, 1859.

"The plans are on the whole conveniently arranged, and merit attention. . . . . It is a handsome volume."—*Building News*, Nov. 4, 1859.

London: THOMPSON and Co., 111, Strand, W.C.

TO TIMBER MERCHANTS AND BUILDERS.
Will be ready on the 15th of January, 1860,
Price 7s. 6d.

THE CALCULATOR; or, TIMBER-MERCHANT'S and BUILDER'S GUIDE. By WILLIAM RICHARDSON & CHAS. GANE, of Wisbech.

Containing about 500 pages, 12mo. Should be on the desk of every one connected with the trade, and will be found invaluable for casting and checking invoices, etc., both in reduction of quantity and money, with other information. Order early of

KELLY & CO., OLD BOSWELL-COURT, STRAND, W.C.

Demy 8vo., 7s., Plans and View.

A HOUSE FOR THE SUBURBS. Socially and Architecturally sketched by THOS. MORRIS.

"Interesting reading, full of valuable information and suggestions."—*Literary Gazette*.

"Beautifully executed, displaying great skill and taste."—*Dublin Builder*.

London: Simpkin, Marshall, & Co., and of the Author, 12, Regent-street, St. James's, S.W.

Imperial 4to, Cloth, Price 12s.

COUNTRY COTTAGES: a series of Designs for the Dwellings of Agricultural Laborers; 20 plates, in Lithography, of plans, views, &c., with letterpress. By JOHN VINCENT. London: E. and F. N. SPON, 16, Bucklersbury.

Will be Published, July, 1860,
A NEW WORK.

ANCIENT IRONWORK from the 13TH CENTURY, containing about 120 most beautiful Examples, in 48 Imperial 4to Plates.
With Letterpress by EDWARD CLARKSON, Esq.
Price, Bound, with Device, £4 4s.
Being a Series of Examples taken from Existing Specimens.
Drawn by D. A. CLARKSON, Architect.
Executed in the best style of Tinted Lithography.
London: ATCHLEY & Co., Publishers, 106, Great Russell-street, Bedford-square, W.C.

On receipt of letter (by post) a New Catalogue sent free.

PHOTOGRAPHIC ETCHING.—A simple method of obtaining, without a Camera or expensive apparatus, Fac-similes, Copies of Plans, Drawings, or any artistic design, entirely free from spherical aberration, and therefore true to scale. Specimens at Architectural Exhibition and Society of Arts. Book of Instructions, post free, eighteen stamps. Wm. Strudwick, 2, Bolton-terrace, Newington, London, S.

MESSRS. JAMES & EDWD. BARKER,
CONTRACTORS
To Her Majesty's War Department, and the Ecclesiastical Commissioners for Ireland.
All orders executed to satisfaction.
32, UPPER ABBEY-STREET, DUBLIN.

ROYAL HIBERNIAN ACADEMY OF ARTS—ANNUAL EXHIBITION OF PAINTING, SCULPTURE, AND ARCHITECTURE. Admission One Shilling. Family Tickets to admit four persons Two Shillings. Season Tickets 2s. 6d.

By Order,
B. MULRENIN, R.H.A., Secretary.

ART-UNION OF IRELAND.—
President—THE EARL OF CHARLEMONT.
AMOUNT OF SUBSCRIPTION FOR THE YEAR,
ONE GUINEA EACH SHARE.

Prizeholders have the right of selection in all cases. Subscriptions will be received by Members of the Committee; by the Secretary, George F. Mulvany, Esq., 113, Grafton-street; and by the Local Agents in Dublin and throughout Ireland. Copies of the Report of last year and Prospectuses sent free by post.

HENGLER'S EQUESTRIAN PALACE, GREAT BRUNSWICK-STREET.

Open every Evening at a Quarter-past Seven, commencing at a Quarter to Eight o'Clock.

Prices of Admission:—Stalls (select), 3s Boxes, 2s. Second Class and Promenade, 1s. Gallery, 6d. Children under Twelve Years of Age Half-price to all parts except the Gallery. Second Price at Nine o'Clock to Stalls and Boxes only.

After the close of the Dublin season, this Establishment will visit all the principal Towns in Ireland.

Director and Proprietor—Mr. CHARLES HENGLER.

MESSRS. TELFORD & TELFORD,
ORGAN BUILDERS.

Several new and second-hand FINGER & BARREL ORGANS, suitable for Church or Chamber, will be sold on very reasonable terms, to make room.

109, STEPHEN'S GREEN, DUBLIN.

TO ARCHITECTS, BUILDERS, ETC.

MESSRS. J. AND J. M'MAHON, to meet the wishes of many friends, have commenced business (after an experience of 20 years) as BUILDING SURVEYORS, MEASURERS, and APPRAISERS, and all matters entrusted to them shall be executed with punctuality, accuracy, and despatch.

OFFICES, ULSTER CHAMBERS, 9, DAME-ST.

TO Architects, Builders, and Gentlemen Building for themselves.—The Subscriber begs to announce that he has commenced business as a MEASURER and SURVEYOR of BUILDINGS, &c., feeling that a vacancy now exists for a person of experience and abilities. He flatters himself he can produce testimonials of the most unexceptionable nature as to his competency and experience. He has been engaged for the past twenty-five years superintending and measuring on the extensive works of the eminent firm of Messrs. COCKBURN and SONS, and, with few exceptions, made out their estimates.

He feels confident he can give the utmost satisfaction to all who may favour him with their orders.

Any communication addressed to PATRICK FEE, 179, GREAT BRUNSWICK STREET, or 14, CLANBRASSIL TERRACE, shall be punctually and respectfully attended to.

The Dublin Builder.

Vol. II.—No. 19.

THE CLOSE OF THE ARCHITECTURAL SESSION.

THE Session of 1859-'60, which commenced last November, has now reached its close, and it is impossible to deny that very great exertions have been made, we will say with undeviating aim; and though we may not, in all cases, add, with uniform success, still zealously made, in the cause of architecture and its allied subjects. Mr. Tite may be said to have opened the campaign in Conduit-street, with a paper, in his usually comprehensive manner, "on the present condition and future prospects of architecture," in which he rapidly glanced at the characteristics and tendencies of the present time, both domestic and foreign.

Then came Mr. G. G. Scott, with his Gleanings from Westminster Abbey; that building, above all others, pre-eminent in mediæval beauty, in historic associations, in the value of its relics, and the ashes of its honoured dead. Mr. Burnell gave a sketch of the improvements in building materials and construction, during the present century.

Another evening was devoted to Mr. Wyatt Papworth's inquiry into the superintendence of buildings in the middle ages, in which he illustrated the subject by a more particular reference to the life of William of Wykeham. But one of the papers, which, to our mind, is of a most important class, from its direct practical character, was Mr. E M. Barry's description of the design and construction of, together with the mode of carrying into effect, the Italian Opera House, Covent Garden; which he accompanied by several of the working drawings.

Dr. Druitt went into the consideration of the construction and management of human habitations, with direct reference to their bearings on health; and in the course of the subject gave some extraordinary instances of early neglect, and of the circumstances attending the gradual development of ventilation and sanitary improvement.

The subject of Symbolism in Art, with reference to Christianity and Architecture, was ably treated by Dr. Barlow; and the origin and development of the use of Crypts was very fully gone into by Mr. Ashpitel. The closing paper, being that of Mr. Digby Wyatt, on Illuminated Manuscripts, exemplified by illustrations in chromo-lithography, by Mr. Owen Jones and other artists, displaying the progress of illumination, from the fifth century down to the introduction of typography.

From this enumeration, it will be seen that subjects of a large and varied scope, all bearing with more or less directness upon architecture, have engaged attention during the past eight months; and it may be noticed, that the observations elicited by the papers read are often of the greatest interest and value, so that did the Institute alone represent the entire architectural sphere, it could hardly be said that matters had been stationary, or that the working within the great seat of centralization had not kept pace with, and reflected, the general movement of the outer world. So far, however, is the Institute from being that sole seat of energy, that many other societies of vigour and importance might be enumerated, as for example, the Association, which, although to some extent absorbed with considerations touching its own vitality, has not failed to render efficient service to the general cause. The Architectural Museum, at South Kensington, where a series of seven lectures of considerable professional value, though treated with an eye to popular entertainment and instruction, was delivered; but in this case the opportunity of discussion is from necessity precluded. The Architectural Exhibition has also produced a similar number of lectures, more strictly appertaining to the subject of architecture, but still addressed to the general public, and rendered in a form suited to popular acceptance. Then there are the Ecclesiological, the Oxford, the Cambridge, and the Liverpool Architectural Societies, which have all been working with more or less of energy and benefit. Would that we were afforded an opportunity of including in the category an "Irish Institute of Architects," but for some unaccountable cause the pleasure is denied us!

But we must not confine our view to the societies alone, when the character of the press devoted to the objects and furtherance of the profession is daily increasing in utility, importance, and public estimation. The most valuable contributions to art and science being by its means widely disseminated and rendered effective in the grand advance of civilisation. Not only are many articles of great value originated in the pages of the architectural journals, but they afford the most ample reflex of those which emanate from the associated bodies, and which, but for the assistance thus rendered, must be confined to the immediate hearers, or, at most, to the subscribing members of those associations. Nor does the usefulness of the press end here; but it attracts to its aid the powers of graphic illustration, thus presenting at once to the eye faithful representations of works, which for their varied associations may be invested with great interest. So we have had, during the last few weeks, in the *Builder* a very accurate representation of the Bridge over the Rhine, at Cologne, intended for the use in parallel lines of the railway, and a road for general traffic. The house of an architect at Paris, which is certainly one of the most *piquant* little specimens, both in plan and exterior, that we have had the pleasure to meet with for some time; and a view of the interior of the Oxford University Museum, a building of very considerable pretension, in which not only is the spirit of the middle ages attempted to be generalised, but the new constructive element of iron is largely employed internally, and in a form of free and even elaborate ornamentation, the illustrations themselves evincing great merit.

In the *Building News* we have had isometrical plans of agricultural buildings, to say nothing of the reproduction of Sir William Chambers' work on Architecture, gratuitously furnished to its readers. An example of Provincial Street Architecture, at Folkestone, where some of the hybrid features of the day are brought under notice; a view of Elvetham Hall, by Mr. S. S. Teulon, in which the prevailing love of banded walls and surface decoration are prominently displayed; a Country House in Norway, unimportant in itself, but deriving interest from its locality, the employment of an English Architect, and the very clever drawing and engraving. The rich features of Spanish Mediæval Architecture are well displayed, by a view of the cloisters of San Juan de los Reyes, Toledo.

An eye has been very properly turned to the subject of public monuments, that is to say, of those most interesting vestiges of remote ages which yet remain, but which have hitherto suffered most extensively from the wanton and devastating hand of the ignorant and inconsiderate. What an Irish antiquary would probably feel, if our round towers were blown down by gundowder, and the materials converted into buildings of the most ordinary and vulgar purposes, we may suppose the British antiquary to feel, when he sees stone after stone removed from such memorials as Stonehenge; and building after building, though of great antiquarian and professional interest, blotted out of existence. Some society or body having for its object the preservation of such works of national interest ought certainly to be established; and though the Institute cannot, perhaps, be said to have taken the initiatory step in this good cause, it evinces a welcome sympathy by its memorial to the Dean and Chapter of Worcester, for the preservation of the Guester Hall in that city; and last, not least, we may notice the agitation which originated a few years since in the Architectural Association, and has been from that source communicated to the senior corporation, respecting professional examinations.

After some preliminary consideration of this subject by the Council of the Institute, a special meeting of members took place on the 25th, when it was resolved, "That it is desirable to afford an opportunity for a voluntary professional examination."

It is well, perhaps, that the simple affirmation of a principle, and a most important one it is, was the only achievement of the evening; for the subject demands extreme delicacy of treatment, and may be permanently prejudiced by one precipitate step. Far better, therefore, was it to pause at the point to which perfect unanimity extended, than to hasten into the field of practical difficulty and diverse opinion.

To see how the case stands, let us look for a moment at the Institute itself, and we behold a body of gentlemen associated for the general advancement of civil architecture, and for promoting and facilitating the acquirement of the knowledge of the various arts and sciences connected therewith. It has three classes of members, one being honorary, and the other two comprising the efficient members, divided by considerations of age, standing, or certain peculiarities of practice; but all bound to abstain from any interest or consideration, except such as may be directly and openly derived from the patron or client, nor can any candidate be elected except on the recommendation of three Fellows.

The operation of such a bond is to place the members of the Institute on a higher platform of public estimation than they would otherwise have held; and it is certainly undeniable that this attested respectability of position, high professional principle, and the concomitant dignity of character, are the very highest credentials that any man courting public confidence could be armed withal: therefore to restrict an examination to members of the Institute, is but to create invidious distinctions, it may be enmities, among honourable men, already raised above their unassociated brethren—to do which is surely needless—"is wasteful and ridiculous excess."

It should be recollected, too, that the Institute, though professing to facilitate, does not undertake to impart, by direct teaching, the information her members are presumed to require, or to possess; while to place an educational barrier on her threshold, might preclude the desire of many to enter, and the sap and sinews of her being would fail.

Now, in our humble opinion, the entrance of all engaged in architecture, who are duly recommended, and are willing to conform to the existing rules, should be by all fitting means encouraged, and the influence of the Institute rendered universal, her funds be augmented, and her power for good increased. This ingathering of all the members should extend however to the associateship, and between that and the higher class of Fellows, the academical barrier should intervene, though in cases of great ostensible merit the Fellowship might be conferred at the instance of the Council, as now done in ordinary.

The examination, though entrusted to the Institute for administration, ought not to be restricted to its members, nor ought it to be of such a character as to preclude those intelligent men, who bring into the general stock a vast amount of practical experience, but are not adepts in theory—who may feel the beautiful, but cannot reduce it to metaphysical analysis. It should not be such, indeed, as would give the prating critic an advantage over the more highly but differently endowed artist.

The examination to which all candidates for District Surveyorships are now subjected, would be quite sufficient as to building science; and a similar inquiry on artistic principles would complete the necessary course which ought to be kept at a minimum, both as a safeguard for the nervous, and against the possible infusion of malice. The examinations should be held quarterly, and be open to all candidates; but the rules of the Institute would always invest its members with a stronger hold on the public mind, and those of the class of Fellows would stand in high social estimation, while the liberal artistic character of the vocation would remain uninvaded and unimpaired.

LAW NOTES.

Cunningham v. *Knox.*—Action for injuries sustained by plaintiff, a hotel and tavern keeper in Lower Abbey-street, by reason of defendant's (the proprietor of the *Irish Times*) machinery used in printing a newspaper in the house adjoining.

Mr. Whiteside, Q C., on behalf of the plaintiff, described his client's case substantially, thus.—The result of the working of the machine was, that when the visitors in the Ship Hotel sat down to dinner, the plates danced before them, and the knives and forks indulged in the same amusement. Cheap news might be a desirable object, but counsel doubted very much if a man would not be sulky if he was to read a newspaper while hungry and deprived of his dinner. The thumping of the engine shook the plaintiff's house. the heat passed through and became offensive, and wooden tops put on the chimneys of defendant's house took fire, burned a hole in plaintiff's roof, and burned the lead on the gutter, besides doing other damages.

The action was ultimately arranged by the defendant paying £5 and costs, and undertaking to have the requisite building alterations made, under the direction of Mr. Murray, architect.

Kempston v. *Butler.*—This action, which our readers are aware is for damages sustained by reason of the fall of a house in Grafton-street owing. as plaintiff alleges, to defendant's neglect as a builder in not taking the proper precaution to shore up, &c , is again, for the third time. before the Chief Justice of the Common Pleas, and a special jury. The proceedings of the last trial were fully reported in our Nos. for March and April, and all particulars together with the evidence of the various witnesses on both sides, being substantially the same as before, we deem it unnecessary to repeat them.

Cooper v. *Gray.*—Action by a plumber for £13 16s. 6d. for contract and extra work, and materials delivered. The defendant only acknowledged £6 2s. 6d. as due on foot of contract, and £4 14s. 6d. for the extra work, which sums were lodged in court, leaving only £3 in dispute. The Chief Justice severely censured plaintiff's attorney for bringing the case to a superior court, and directed his client not to pay him any costs, and the attorney to pay all costs if there was a verdict against his client. The case was settled by the acceptance of the sums lodged in court.

M'Curdy v. *Taaffe.*—Action for damages for injury to a house in Cole's-lane, adjoining defendant's, by interfering with the foundation of a flank wall. Defendant traversed the allegation. Several professional witnesses were examined, whose evidence as to the cause and origin of the damage was contradictory. Verdict for the plaintiff, £100 damages, and costs.

Colley v. *Connolly.*—Action for £251 9s. 8d. for work and labour done as a builder, and materials provided. Defendant pleaded no agreement, that the alleged cause of action did not arise within six years before the institution of the suit, &c., &c. Verdict for defendant, with 6d. costs. Counsel for plaintiff—Messrs. Armstrong, Q.C., and Malley; for defendant—Messrs. MacDonough and Walsh, Q.C's., and Walker.

Burke v. *Carroll.*—Action brought by the proprietor of the Shelbourne Hotel, against a neighbour, Dr. Carroll, for alleged damages owing to defendant having caused to be pulled down a stack of chimneys, by which plaintiff sustained material injury. Defendant denied that he committed the damage. Verdict for the plaintiff, £10 damages and 6d. costs.

Michael Brophy Moran v. *Walter Bourke.*—Action by an architect and surveyor to recover a sum due for making drawings, surveying. and superintending erection of sundry works, measuring and valuing buildings, paying workmen, &c., at defendant's request. A sum of £5 was lodged, but Mr. Sidney, counsel for defendant, offered £20 as payment for debt and costs, to which plaintiff's counsel acceded.

Meighan v. *Baker.*—Action by a builder to recover £662 claimed as a balance for the erection of a residence, Frankfort Castle. Co. Dublin. The Chief Justice said he had been considering this case. and he found that it was purely a matter of account, which could be better investigated by an architect than in that court. He would, therefore, suggest that the question in dispute should be referred to arbitration. The parties adopted his lordship's suggestion, and agreed to refer the matter to the arbitration of Mr. Murray, architect, Lower Gardiner-street.

The Chief Justice said that if any question of law arose, he would be happy to receive Mr. Murray in his chamber, and afford him any assistance he might require.

Counsel for the plaintiff—Messrs. Rollestone, Q.C., Kernan, Q.C., and Heron. Attorney—Mr. H. K. Butler. Counsel for the defendant—Sergeant Fitzgibbon and Messrs. Armstrong, Q C., and Sidney. Attorney—Alderman Hudson.

THE *AUSTRALIAN BUILDER*—MELBOURNE.

OUR professional brethren at the antipodes are represented by a publication of similar mission to our own, and judging from a recent No. (14, vol 2), that has reached us, the conductor is turning comparatively limited resources to such good account that we anticipate a very prosperous future for the undertaking. Through its pages we learn that there is to be a competition for "the new Bank of Victoria," that there has been "a turn-out of masons at the Treasury buildings," that there is "a Victorian Institute of Architects" holding monthly meetings, at which valuable papers are read; that there is also "a Builders' and Contractors' Association" in the colony, together with information relative to local building matters, Original papers on appropriate subjects are also introduced. We say with all sincerity to our contemporary, "go on, and prosper."

DISINTEGRATION OF GRANITE.

THIS mineral, in its perfect form, consists, as our readers are aware, of three constituents—mica, feldspar, and quartz. The mica being that shining substance which may be detached by a sharp instrument in their flakes; the quartz is the hard white body which the masons call horsetooth, when in large irregular pieces; and the feldspar is the cementing medium in which the others are embedded.

Sir Gardner Wilkinson has noted the liability of the feldspar to decay under the action of nitre, so that in Egypt, where a block of granite has by displacement or accumulation of soil been brought into contact with the earth, the granite has suffered from nitrous agency, while, where exposed to the air only, it has remained perfect. The fact, he thinks, was well known to the ancients, who usually placed granite on a foundation of sandstone.

When this communication was made to the Institute the other evening, the President remarked, that granite, which at a time within his recollection was applied almost exclusively to paving, had now acquired an important position among the materials at the architect's command, and that observations of this practical character were therefore of the greatest value.

A partnership has been entered into between Mr. J. J. M Carthy, M.R.I.A., architect, and Mr. Daniel O'Connell, grandson of the "Liberator," and late pupil of Mr. Hansom, of London, architect.

The distribution of prizes to the students of the Government School of Science applied to Mining and the Arts, took place on the evening of the 25th ult., at the Museum of Irish Industry, Stephen's-green, East, at which His Excellency the Lord Lieutenant presided, and delivered an appropriate address.

AMUSEMENTS.—Madame Celeste and her Royal Lyceum Company, including Miss Kate Saville, Messrs. James Vining, Villiers, Rowse. Johnston, &c , terminated a very successful engagement here on the 19th. The magnificent transformation scene from "King Thrushbeard" elicited universal commendation.

THE ARCHITECTURAL PROFESSION.

THE architectural world seems to be in that state of peculiar confusion that precedes every revolutionary crisis. For years past it has been rushing on like a reckless stream—swelling beyond its bounds with alien waters, and carrying strays and rubbish to that mighty sea of Commerce which imperceptibly and surely increases. No longer is the cool and refreshing ornamental, health-giving water decked on each side by the classic schools of Greece and Rome, or the sombre though majestic lake—as we could picture to our imagination for a simile—reposing beneath the moonlight in Gothic splendour. No! the stream has become muddy, and how little mud taints the whole! Our ideas have become commercial, rather than tasteful or artistic. That all-important and all-powerful revolutionist, money! is working the change. To attempt to stem the torrent individually, would be rushing to certain destruction; to write, and fill whole pages with indignant ink, will be but waste of time that could be more valuably spent, perhaps, and treated by those whose cause it is intended to espouse, as theoretical and useless.

To come to the point, then—in what does this mud and rubbish consist, tainting our architectural river? The cause is a commercial spirit of activity and speculation; the effect is deterioration of the architectural profession. Your man of capital builds; he wishes excellence and cheapness, two articles that by a strange process peculiar to juggling are now made to class together. He thinks he gets them, at any rate the latter, and charitably leaves it to his heirs to discover what sort of heirloom it is. Finding such a sudden rage for cheap houses, surveyors, valuers, auctioneers, have entered the field; and now what is the result? Members of a scientific profession are frequently known to undersell their commission to purchase a job—we do not say these compose originally the clear part of the stream (the simile that we have adopted), but they certainly lay claim to the mud and strays of the polluted river. "Get money honestly if you can, but get it," seems to be the maxim generally followed, and we cannot see any difference or distinction between commercial monopoly—or fraud, and architectural want of faith, or using means of competition which the user would be ashamed to avow. The jerry-house building, then, has given rise to so many evils, that we scarce know on what side to face the hydra-headed. Unfair competitions, professional disputes, and public suspicion follow, and the coming generation of architects must be content to bear the punishment for the sins of their fathers, if they would attempt to revive the true spirit of architectural science.

To rake up the competitions unjust, and competitors maltreated, will be useless; enough of this is done every day to shew the mischievous system that is prevalent. We are daily importuned to expose some scandalous trickery, but such things are so managed as to elude proof. It must all work its own cure; the assumption of degrees by the Institute of British Architects and the Architectural Association, perhaps, will do little if not coupled with a determination among the members to reform their professional morals. Acts of parliament cannot moralise people, nor can degrees really elevate a profession whose members will not elevate themselves; but in such a case we should have the consolation of knowing that they who aim at fine houses at small prices, fee included, cannot derive the glory of having employed first-rate talent, or what is considered as such. If the conferment of degrees be honorably and rigidly enforced by *practical* examinations and admissions, then indeed we may hail it as a regenerator of the architectural profession. It will at least constitute a citadel from which legitimacy may eject the bastard or irregular, and be a rallying point for those who work harder than any other profession, in proportion to their profits.

Consider the case of the engineer, and his work in proportion to his commission—we mean the civil engineer. Suppose the works he is entrusted with to be railway, dock, or otherwise. He gives plain, general directions, and his drawings are carried out by subordinates, and the work by others, without requiring that practical supervision which an architect in an elaborate structure is presumed to use. The most trifling ornament placed wrongly may derange the whole of the design; it is a work of detail, and as it rises, ideas occur by certain combinations of form, colour, light, and shade, that the architect must constantly think, contrive, and execute. The engineer generally has his whole scheme planned, and, being rather precise than artistic, it must fall, each portion to its place, and when finished, is really so, and he has done with it. He hands it over to the contractor to keep in proper repair for a twelvemonth, and responsibility is off his shoulders. But the architect's work is never finished—a tint here or a finial there, and so on, and he has not a truly architectural soul who cannot watch over his production after its completion as a mother her darling child. We bring forward this in support of our assertion as to the architect being the hardest worked professional man in existence in proportion to the remuneration he receives.

To return to our subject—the present relative position of the genuine architect and the *quasi* one, reminds us somewhat of the satirical description in "Gil Blas" of the reception of the author by the "comedienne," wherein the sporter of others' brains assumes the dictatress and bombastic. Very much akin to this parallel is that of the architect and builder of the present day, who, though they cannot of necessity be hostile, need not so energetically play into each others' hands. Truth is unpleasant, but it must be spoken, and we as faithful chroniclers must speak it.

The agitation going on in the metropolis concerning the assumption of degrees by the Institute, to which we have already had occasion to allude, if properly carried out, will indeed be a step in the right direction, and may tend to exalt, whilst it instils the principle of study into the younger members of the profession to gain an honorable grade, which we only hope may be done without cramming, as is fashionable now-a-days.

HARD CEMENT.—The following cement has been used with great success in covering terraces, lining basins, soldering stones, &c, and everywhere resists the filtration of water. It is so hard that it scratches iron. It is formed of ninety-three parts of well-burned brick, and seven parts of litharge, made plastic with linseed oil. The brick and litharge are pulverised; the latter must always be reduced to a very fine powder; they are mixed together, and enough of linseed oil added. It is then applied in the manner of plaster, the body that is to be covered being always previously wet with a sponge. This precaution is indispensable, otherwise the oil would filter through the body, and prevent the mastic from acquiring the desired degree of hardness. When it is extended over a large surface it sometimes happens to have flaws in it, which must be filled up with a fresh quantity of the cement. In three or four days it becomes firm.—*Scientific American.*

ON ECONOMY OF FUEL, IN DWELLING-HOUSES, PUBLIC BATHS, AND FACTORIES.

In drawing attention to some methods of preventing waste of heat (and consequently of fuel), I beg to premise that I am not about to advocate bad fires and deficient warmth; nor do I flatter myself that I can lay claim to any great originality in the means which I recommend. It is, however, of equal advantage to the public, as if some ideas (previously unknown) were for the first time brought forward. What can be more absurd, than to object to the adoption of a principle, that we have heard of it before; if, all the time, we ignore its existence, and act as if the opposite view of the question were the true one? When I say that the atmosphere itself is one of the best, and cheapest non-conductors of heat that has ever been discovered, I do not tell you anything new; but I lay down a principle, whose existence seems to be forgotten, notwithstanding the beautiful exemplifications of its truth which nature furnishes in such never-ending profusion. In the fur of the quadruped, in the winter garment of the earth, in the soft lining of various spring buds, and in the husk of the cocoa-nut, which is to resist the sultry beams of an equatorial sun, we see the perfect arrangements of an All-wise Providence, for the purpose of preventing the too rapid transmission of heat, from within outwards, or from without inwards. Man knows how to avail himself of the non-conducting properties of natural substances; but he will not adopt the simple expedient which pervades them all, of using confined strata of air, as barriers against the conduction, or convection, of heat. That the so-called warmth of wool, fur, feathers, silk, &c,, is really owing to the entanglement of air in their interstices, is a fact which can be very easily demonstrated; and it is obvious that where high temperatures are to be endured, the medium selected as non-conductor, must be such as not to lose its properties in consequence of the heat to which it is exposed.

Now, it so happens, that no ordinary substance, with which we are acquainted, is so little altered in this respect by heat as atmospheric air, and it therefore affords a much better protection against its escape than most of the substances which are now employed with this view. Of this I shall say more when speaking of the construction of baths; but, as our greatest national consumption of coal is in its domestic use, I shall first say a word about the construction of grates; and especially of the kitchen grate, where cooking is performed. The abundance of coal and iron in England lead us into two great errors in the construction of fire-places; as we are thus disposed to waste the former, and to make too frequent use of the latter. If I address anyone who does not care (personally) how much coal he consumes, let me remind him that the amount in our mines can never be increased, however much it may be diminished; and that, therefore, every day's consumption enhances the value of the remainder, and diminishes the comforts of the poor. I do not speak at random, when I say, that very high authorities expect a great rise in the price of coal during the life-time of the present generation. And, as our continental neighbours are now being provided by us with the above-mentioned munitions of war, we may expect a further advance in the value of our staple productions. It may, perhaps, surprise some to be told that a fair representation of the amount of coal annually consumed in England alone, would be a mass of it equal in area to the surface of Hyde Park and Kensington Gardens, and in height to that of the tallest houses in the neighbourhood. But, perhaps, it is unnecessary to say more to prove the importance of wisely using so great a material blessing. The disadvantage of using much iron-work in the construction of fire-places, intended to throw heat forward into a room, is very apparent. That iron is a rapid conductor of heat, is well-known; and it is also known to be exceeded in radiating properties by bricks and other cheap and common substances.

The amount of labour and knowledge required to set a few fire-bricks in the back of a grate, ought, surely, not to be a very formidable barrier against their substitution for a material which is dearer to put up, and more wasteful of fuel than a properly-constructed fire-place. It also appears to me very strange, that almost all grates (as now constructed) should have sloping backs, which throw the heat rather upwards instead of directly into the room. The latter object may be accomplished without impairing the draught, by only commencing the slope at the top of the fire-place. The coverings of ordinary grates are also too oblique, (and therefore badly suited for reflecting heat) as may be seen by comparing the best reflecting surfaces, when at a wrong angle, with the worst, when properly set. I once set a grate myself (with the assistance of a journeyman mason), making the covings at each side, at about an angle of 45 degrees with the back, (which latter was nearly perpendicular); and I can vouch for the amount of heat thrown out, although there was no metallic surface to reflect it. Perhaps this may be the proper place to remark that the mantels of fire-places are generally placed too high above the grate, which occasions an influx of cold air into the chimney; and, in windy weather, very often causes the smoke to puff backwards into the room, from the diminished draught occasioned by the cooling of the smoke. It is quite amusing to see the number of kitchen-ranges which now advertise their rival pretensions to convenience and economy, but I should be flying directly in the face of the public interest if I were to recommend the general adoption of any one of them. The mass of metal in them is so utterly disproportioned to that which ought to exist in any fire-place, that even if they were cheap as regards first cost (which none of them are), they might be stripped, on this ground alone, of all pretensions to economy in the application of heat.

Most of them are also constructed with but one fire-place, which is intended to heat an oven, or roaster, on one side, and a boiler on the other; and the mode in which this is effected is by the creation of a strong draught which causes the flame to rush violently over (and partially at the side of) the boiler, and oven; but never directly under them. It is easy to see that where there is a strong draught, no contraction of the fire-place is any guarantee of diminished combustion, and it is also very plain, that if a given amount of heat be generated, the more directly it is applied, the sooner will a proper temperature be attained. In the ranges alluded to, the metal plates on the top sometimes get red-hot during cooking, thus giving evidence of the heated condition of the air which is suffered to escape up the chimney. This is the secret of the efficacy of these ranges for the cure of smoky chimneys, which they certainly do effect, but in the most expensive conceivable manner. The same amount of draught may be produced in any chimney by bringing down the mantel, removing the hobs, and contracting the throat of the chimney to reasonable dimensions, whilst the flame may be made to give off heat (where it is required) before it escapes, (as cool smoke), into its proper flue. There can be no doubt at all but that the best position to apply heat to an oven or boiler is directly under it, as fluids are heated by convection; and the heated particles have a natural tendency to ascend. This principle is duly attended to in some continental ranges, and the practice is certainly as old as the time of Count Rumford, who erected a kitchen for the Baron de Lerchenfels, of which I have here a rough sketch, showing the disposition of the flues. It represents a mass of masonry, extending two or three yards into the room, and furnished with several distinct fire-places, all of them small, and situated directly under the principal boilers and stew-pans. The flues from these fire-places give off their heat successively to several vessels before they enter the chimney, and as they are double (or surrounded by strata of confined air) no loss of heat by conduction is experienced. In addition to the damper of the modern ranges, the fire-places of this kitchen have separate doors to the ash-pits, provided with register-slides. to regulate the amount of air to be admitted. The quantity of fuel consumed in this range is stated by Count Rumford to be small, and the quality of the cooking unusually excellent. The covers of the fixed boilers are all double, and therefore, their contents are very easily kept warm, as none of the heat is abstracted by the atmosphere. I may be told that this is very fine in theory, but that practical men will not adopt such ideas, because they find they can do very well without them. Of course there is no use in reasoning with a person who declares that he has no desire to do better, when he knows of a better way; but any one who really doubts that much heat can be lost in this way, can easily satisfy his mind by placing his fingers on the lid of a boiling pot or kettle having a single cover; and if burning his fingers does not convince him, anything that I can say will have little effect. The same principle is indispensable for furnace doors, which ought never to be single, the outer plate being made a little larger than the inner, thus forming a rim which shuts against the frame. I need hardly say that when rooms are required to be kept at a high temperature, the walls ought to be built double, as the truest economy in the end. The stratum of air enclosed ought to be, at least, equal to the thickness of a brick, and will form so good a barrier against conduction, that the outer wall will be scarcely perceptibly warm. This mode of building was well understood by the Romans, and is practised by the modern Turks in the construction of their Baths. The ventilators of these, and of all other buildings ought to be in, or near the ceiling, as the Romans were also aware, although Vitruvius imagined that the air came down through them instead of going up, as it must necessarily do. In the construction of furnaces and boilers, we are far ahead of both the Romans and Turks, and therefore we can learn nothing from them; and the ordinary furnaces which are employed in factories will be found well-adapted for the heating of public baths. I have examined the construction of the heating apparatus in some large establishments, viz.—baths, breweries, and in a factory employing at least a thousand hands, and do not hesitate to say that some points require more attention than has yet been given to them. The simple matter of controlling the ingress of air into furnaces (when the combustion is too rapid) by means of register-slides to the closed ash-pit doors, is seldom or never put into practice, and most firemen continually leave the ash-pit door open. But the most important suggestion which I wish to make, for the prevention of the entrance of cold air into the furance, is respecting the operation of stoking. Everybody knows that periodical clouds of black smoke are seen issuing from factory chimneys, when this is going on, and that such smoke represents soot to be breathed by the public, and coal to be paid for by the proprietor of the factory. Now, it seems to me, that the chief reason why there is so much smoke on these occasions is, because cold air rushes into the furnace when its door is kept open; and that at the very time when the presence of a quantity of fresh fuel makes combustion difficult. To obviate this, the plan recommended by Count Rumford seems to be very efficacious. It is simply the construction of a porch opposite the furnace, with a close window and a well-fitting door. It should be large enough to contain a few charges of coal, a seat for the stoker, and the ashes which may be raked out in twenty-four hours. The door may be left open except when stoking is going on, and should then be closely shut. The effect is, that the cold external air no longer rushes into the furnace in a torrent, carrying off the heat and preventing the combustion of the fuel which has been freshly thrown in. If this porch could be entered by an ascent, the effect would be still better, as heated air naturally accumulates in the top of a room which is not provided with a ventilator. We may even learn in this respect from the practice of the uneducated Esqnimaux in the construction of their snow-huts; and from the vapour-bath of the Russian peasant, which costs him nothing but the labour necessary to scoop out a cave in some bank, and to arrange a few hurdles round its sides at some height above the floor. As it is impossible to disconnect the subjects of warmth and ventilation, I shall take this opportunity of bringing forward an idea which lately struck me, by which the flue of the kitchen fire may be employed for creating a draught sufficient to ventilate an entire house. I am not unaware that the kitchen chimney has often been proposed as a receptacle for foul air, which thus is discharged along with the smoke; but I think the same object may be much better effected by keeping the smoke flue perfectly distinct from that which carries off the consumed air of the house. My proposal is to let them lie so near one another (only separated by the thickness of a brick) that the air-flue may be sufficiently warmed throughout its whole extent, to excite a gentle current of air upwards through the flue. This air-shaft may begin at the bottom of the chimney and be continued upwards until it discharges at the base of a chimney-stack, or under the eaves of the house. Communications may be made with every room by short tubes commencing at the ceiling directly over the mantel-piece, and running into the air-tube, which never puffs back smoke, like Arnott's, or other valves opening into the chimney.

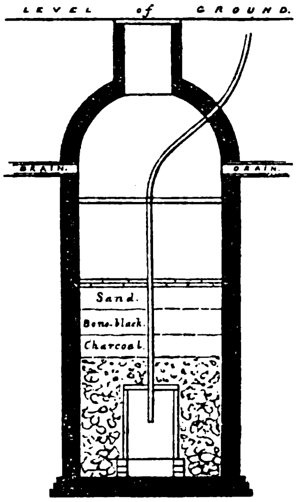
This system will work well if the fire be freely supplied with air, but in tightly closed rooms the current will set down the air-shaft to the supply of the fire. To obviate this, air-tubes from without may be carried under the grate so as to allow the warmed air of the room to remain, until gently wafted upwards by its own altered specific gravity. In a complete systen of ventilation all these tubes might be regulated to the greatest nicety, so as to alter the temperature of a room immediately without poking, or otherwise interfering with the fire. This is best effected by register-slides, such as I have already described. Tubes to admit air into the body of the room can also be adapted when required, being made to pass at the back of the fire so as to warm the air in its passage; and may be made to open in any position, or by any number of apertures, by carrying small branch tubes round the floor or walls of the room. A perfect arrangement of this kind, is (of course) unattainable by the poor, but if the principles I am advocating be sound, the poorest cottage in the land may at least have a properly-constructed grate, and a ventilator in the right position. Moreover, physiology teaches us that less food is required when the body is kept sufficiently warm, and therefore, any plan which will enable the poor to maintain a better degree of warmth within doors (without restricting the ventilation), must diminish their expenses as well as increase their comforts. These considerations invest the subject with no ordinary interest, and as we cannot do without fuel, nor increase the quantity which the country now possesses, it is plainly the part of wisdom to construct our fire-places in such a manner that the heat actually generated may not be suffered to escape without being of some service to us. I have carefully avoided allusion to the housekeeper's province, as I do not think that a careful builder will throw the "onus" of management on the occupants of a house; nor do I think that stinginess has any pretensions to be called economy, and should never be confounded with it. On the contrary, I consider a genial warmth within doors to be both conducive to health and happiness, and perfectly compatible with real Economy of Fuel.

E. HAUGHTON, M.D.

Mr. Keile, the eminent architect, has erected no less than 197 Catholic Churches in various parts of the United States.

FILTRATION OF WATER.

CONSEQUENT upon our remarks at page 283, concerning rain-water as an auxiliary supply for towns, a suggestion has been made to us by an architect for a simple and rapid method of filtration applicable to insulated situations and country houses, where the observance of economy in water may be necessary.



Let the rain falling on the roofs of such buildings be conveyed by gutters, pipes, and drains to a tank or water-tight reservoir sunk deep in the earth, and a separate set of drains be provided for taking off the slops and sewage to another and distant receptacle.

We may assume the rain-water tank to be six feet diameter in the clear, and the bottom to be twenty feet below the surface of the ground, the sides and bottom being built of brick in cement and lined with a coating of tiles. On the bottom let a few circular courses of bricks be built in the middle, forming a ring two feet diameter and nine inches high, without mortar or cement of any kind. Upon this, place a length of the large stoneware drain-pipe, with a stone cap cemented on the top, and a perforation in the middle for the suction pipe of the pump, which must be inserted and have the joint made close. The pipe having been fixed and brought up to a wooden stage near the top, the well has to be filled with clean rough stones, large at the bottom and diminishing in the successive layers. There must then come some wood charcoal, mixed with the animal charcoal or bone-black, and then some fine shingle and sharp grit-sand, covered loosely with flag-stones or tiles, to prevent displacement by the fall of the water as it enters from the drains. It will now be obvious that as soon as the pump draws the water upwards in the suction pipe, it takes that which has first percolated through the screening beds, and a corresponding action must be kept up whenever the pump is at work.

It may be worth an enquiry whether filtering pits on this principle would not be suited to the purification of stagnant lakes such as the Serpentine, of which so much has lately been heard? They must, for such a purpose, be sunk below the bed of the lake.

ART PRIZES OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

WE may serviceably, at this season, remind our architectural and engineering readers of the medals which are open to their enterprise and talent, as the rewards of this body are calculated to confer a high and permanent distinction on those who obtain them.

There is the INSTITUTE MEDAL for the best Essays on—

1.—The application of wrought iron to structural purposes.
2.—The application of wood in England, constructively and artistically, from the year 1500 to the present time.
3.—An essay on the introduction of Italian architecture into England, particularly with reference to the influence therein of John of Padua, or John Thorpe.

The SILVER MEDAL, with five guineas—

For measured illustration of a mediæval building, in Ireland, Scotland, or Wales, hitherto unpublished in that manner.

The SOANE MEDALLION—

For a design of a grand railway station, adapted for the junction of two or more lines of railway.

This medal is limited to persons under thirty years of age, and carries with it the chance of a travelling gratuity of £50.

Kilconnell Abbey,[*] Galway, was the subject of Mr. Blake's drawings two years ago, and obtained for him the medal and five guineas, with some very encouraging words from the late Earl de Grey, the President, whose name is remembered with honor as our Lord Lieutenant.

⁂ We advise those who think of studying these subjects, to obtain the printed particulars from the Honorary Secretaries to the Institute, T. H. Lewis, Esq., and James Bell, Esq., 9, Conduit-street, London, W.

---

[*] We regret to notice in the "*Building News*" of June 8, an obituary record of Mr. Blake, who obtained the medal for his memoir and sketches of this Abbey; and who was—as stated in our contemporary, a native of Galway.

THE NEW KILDARE-STREET CLUB-HOUSE.

THIS building is rapidly approaching completion, the masonry and brickwork being quite finished, and the planting of "the flag" celebrated convivially by the contractors' employées at the expense of the club, whose members thereby laudably revived a time-honoured custom. A multitude of hands are busy at the interior, and the decorative portions generally; and whatever may be the opinions entertained by fastidious critics, respecting the architectural merits of the building, it must be conceded by all, that it is the most important structure of its class in Ireland; and we may add, that we hope to see many others equally so, speedily reared in this metropolis. We present, herewith, a plan of the principal storey, whose features explain themselves; and as a lengthened description of the building appeared in a previous No.,* we refer thereto for further particulars.

BUILDERS AND THEIR SECURITIES.

WE learn that it is a practice amongst some public bodies, to require from builders contracting for the execution of certain works security to *double* the stipulated amount. Really this seems to be preposterous in principle, and certainly is vexatious to the trade generally. As a rule, every public body and every private individual has a right in embarking in building matters to protect his own interest, and ensure the due performance of the contract by obtaining security to the *amount* in question—though there are various exceptional cases in which it might, with perfect safety, be altogether dispensed with, and the employer protect himself beyond the possibility of an exigency by making only proportionate advances—say two-thirds—on work executed and materials delivered. But why security to *double* the amount should be necessary seems to us inexplicable. The Board of Public Works adopts the course suggested, and it forms an excellent precedent for all other departments.

ST. PATRICK'S CATHEDRAL,

REFERRING to the "restoration" now being proceeded with, a correspondent (Fides) thus writes—

"Having heard of the doom which now threatens our ancient cathedral of St. Patrick, I was induced to visit the building last Sunday, and with much regret perceived that the work of destruction was rapidly advancing; scaffolding had been raised for the support of the roof, windows have been ruthlessly broken away, and apertures made through the walls for the introduction of beams of timber, &c. I understood that the whole of the south wall of the church, with its flying buttresses and graceful demi-arches, and the beautiful south transept, or chapel of St. Paul, (now the only remaining ancient portions of the building, with the exception of the great tower,) are to be altogether removed and re-built. Is this, may I ask, what is called *preservation*, and can the Cathedral, after it has undergone handling, be deemed an ancient one, when not a stone of the original building can be said to remain? And is there really no other alternative than thus to destroy these last remaining relics of antiquity? the walls appear perfectly sound throughout, and the flying buttresses at the south-west part of the church seem strong enough to defy the power of time. The arches on which the walls of the nave rest, have lately been repaired and new columns been erected; ought not this, with the proposed groining of the ceiling by supporters springing from the columns, with the addition of two or three buttresses on the outside where the walls were deemed weakest, be sufficient to strengthen the building, and at the same time preserve its ancient attributes? Indeed it is strange if the architectural skill of this city could not devise some means for the preservation of a building that has so long withstood the hand of time, and carried down, even to our own day, some traces of its original grandeur, despite the storms, the wars, and vicissitudes of five long centuries, and, worse than these, the improving hands of modern vandals."

MEDIÆVAL ART IN METALS.

THE devotedness with which our brethren at the other side of the channel have applied themselves to the revival of mediæval art in Ecclesiastical structures, is especially noteworthy in the department of furniture and decorations, an excellence being attained therein, both in originality of design, and beauty of manipulation, by some of the modern manufacturers, fully equivalent, if not superior in many respects, to the works of any of their great prototypes. On more than one occasion we have noticed in this journal, from observation either during personal visit to the manufactories or otherwise, the executed designs of some of the firms most eminent in this line; but we are, nevertheless, not thereby precluded from recurring to the subject where additional novelty is offered in the communication. A new and improved edition of an illustrated catalogue issued by Mr. Thomas Brawn, of Birmingham, now lies before us, and it comprises numerous original patterns—both external and internal—in the mediæval style, of church utensils, ornaments, and furniture. We learn that the author and manufacturer was, for a lengthened period, intimately connected in a mechanical department with that great Master of Gothic Art, the late A. Welby Pugin, and, doubtless, imbibed more or less the principles of a school whose pre-eminence is universally patent. The sketches throughout the catalogue, which are given in a free and bold style of pen-and-ink etching, are effective, and the designs both in detailed and grouped subjects, most meritorious. It will be found to be an acquisition to the Clergyman, the Ecclesiologist, the Church Architect, and Builder, and in fine, to all connected with the rearing of Ecclesiastical structures.

"ANGLO-HIBERNIAN ROMANIST" ARCHITECTURE.

UNDER the foregoing somewhat complex heading, our contemporary, the *Ecclesiologist* for June, notices the designs of "English Architects for Churches said to be on the eve of erection in Ireland;" but we have good authority for knowing that *at least* one of those referring to a local structure, and even presumed by the reviewers for kindred periodicals of the drawings at the recent Royal Academy Exhibition, to have been completed, is not only not yet commenced, but not commissioned. National spirit is not quite departed from the country; and as long as we have the testimony of works actually erected, and of such designs as many as those exhibited for the proposed St. Andrew's Church, we apprehend that no necessity exists for calling in foreign aid, more especially if volunteered to the detriment of our own practitioners.

SOLID PARQUETRIE FLOORS.

THIS invention, by Messrs. Arrowsmith, of New Bond-street, London, seems to find favour amongst not only our architects, but amateurs of refined taste. Sir Thomas Esmonde, Bart., of Johnstown Castle, Wexford, has had his principal reception-room laid therewith, as also an interlaced pattern introduced with considerable effect into the dado of the apartment, as similarly applied in numerous instances in England. About 2,000 feet of this flooring has also been laid by the patentee, at the newly-erected and magnificent mansion of Phineas Riall, Esq., at Old Connaught, Bray, Messrs. Lanyon and Lynn, architects, and it is said to the great satisfaction of all parties concerned. The invention combines the advantages of endless variety of patterns, applicability to any and every style of architecture, and durability of wear.

NEW INVENTION TO OBVIATE RAILWAY COLLISIONS.

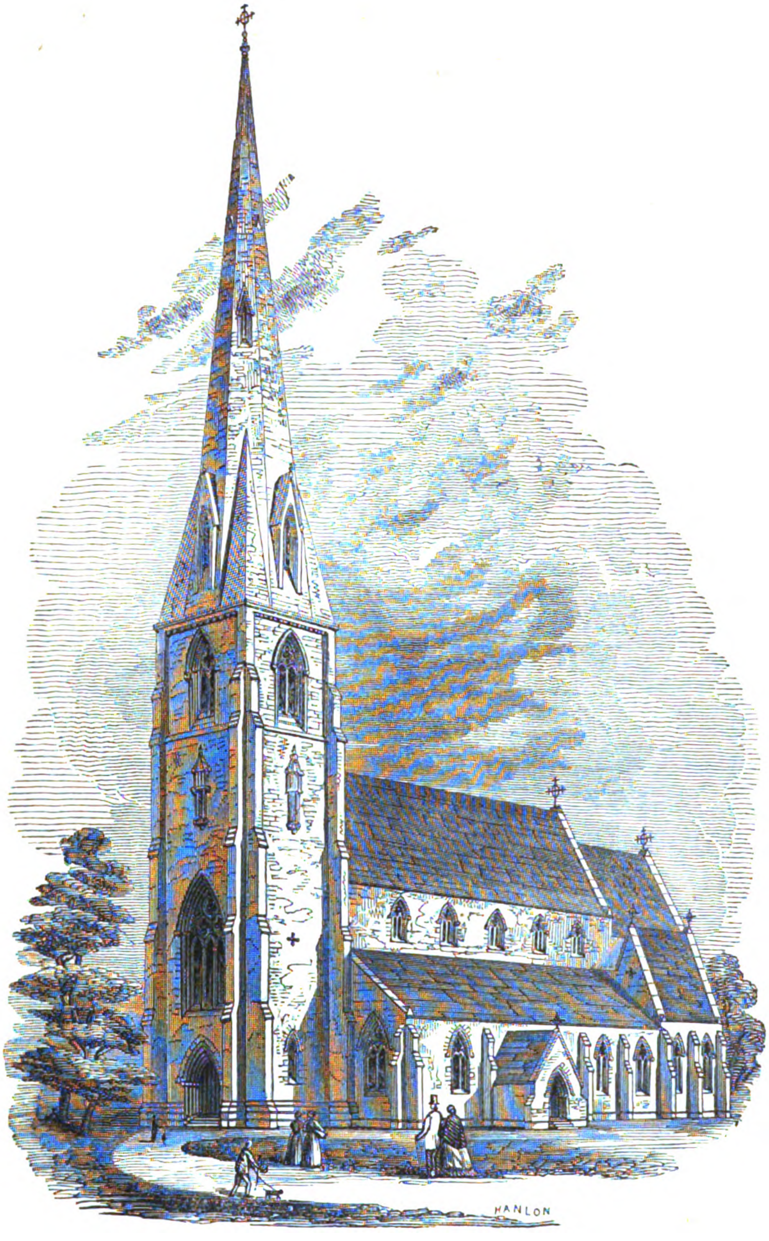
AT a recent meeting of the Royal Dublin Society, Dr. William Bevan communicated some particulars, illustrated by a diagram, of an invention which he alleges will obviate collisions on railways. He stated that, "hitherto the effort used to prevent a collision was the pulling up of the train, that the momentum of the train was generally such as not to allow of stoppage—steam off, and break on—within a less distance than half-a-mile; that statistics showed that very little injury to life and property occurred where the train slipped off the rail." This gave him the hint for his invention, which was a wedge projecting from the front of the engine at the right-hand side. Two trains coming in opposite directions, the engines having these wedges would, when they met, be forced off the line by the transverse forces coming in contact, and the trains would pass side by side. Dr. Bevan promised a model at next meeting. The chairman (Dr. Waller) expressed a doubt of the efficiency of the invention, and Professor Haughton said that the mechanical theory was correct, but how was it applicable when trains met *in* an embankment? (A laugh.) We presume that of the two evils the unhappy passengers might choose the least!

---

* See page 144, Vol. 1.

HOLY TRINITY CHURCH, COOKSTOWN.

This building—of which we give an illustration—was consecrated on the 3rd ult. by the Most Rev. Dr. Dixon. The plan is a parallelogram, and combines all the requisite arrangements for a symmetrical and commodious parish church. It consists of nave, 80 feet by 25 feet; aisles, 80 feet by 14 feet, separated from nave by an arcade of pointed arches, 23 feet 6 inches, to soffets, and springing from circular shafts; chancel, 32 feet deep; tower, 12 feet 6 inches square; chapels of the Blessed Sacrament and Blessed Virgin, sacristy, and vestry. The interior is lighted by aisle and clerestory two-light traceried windows, three-light ditto in the side chapels, and a five-light in the chancel, filled with stained glass, by Messrs. Hardman, mediæval artists, of Birmingham and Dublin—the upper compartments containing symbols of the Blessed Trinity, and forming a memorial of the late Rev. Canon M'Conville: and the lower displaying figures of St. Patrick and canonized bishops of the diocese. The roofs are of open timber-work, stained and varnished, arched ribs being introduced over nave. The height to wall plate of nave is 36 feet; to ridge, 57 feet 6 inches; and to wall plate of aisles, 16 feet 6 inches. The chief entrance is through a deeply-recessed and moulded arched doorway in the tower, which is placed central on west elevation, and will, with the spire (when completed), attain a height of 175 feet. The label moulding of this door is supported on two corbel heads, representing St. Patrick and St. Athanasius. An inner porch of massive wood-work protects the interior of the church from draughts, and forms the groundwork of a beautiful organ gallery. The high altar is of Caen stone, by Mr. Lane, of Dublin and Birmingham. It is a magnificent work of art, with a frontal consisting of three panels, enclosing sculptured representations, in bold relief, of the Last Supper of our Lord (the institution of the sacrifice of the New Law) and the typical sacrifices of Melchizedeck and Abel. The panels are separated by shafts of highly-polished coloured marble, with moulded bases and foliage capitals. The interior fixed carvings are by Messrs. Purdy and Outhwaite, of Dublin. Mr. J. J. M'Carthy, A.R.H.A., was the architect, and Messrs. Johnson (M. D.) and Charles, the contractors.



NEW CHURCH OF THE HOLY TRINITY COOKSTOWN—Mr. J. J. M'Carthy, A.R.H.A., Architect.

DALKEY.

Bountiful as has been Nature, in her general dispensation of gifts to our "Green Island," she was peculiarly beneficent in modelling the subject of this sketch. Supremely picturesque, replete with noble and romantic grandeur—poetic even in its pristine rudeness—hallowed by historic associations, and dignified with the prestige of *ci-devant* royalty, "Dalkey," within eight miles of the Irish metropolis, and possessing a facility of access by rail, reducing distance to a time consideration less than that between the metropolis and other much nearer, less beautiful, but more *fashionable* suburbs—remains comparatively neglected; still a wild, barren waste, a field whose apparent infertility seems, with few exceptions, to deter modern innovators and speculating capitalists from investment.

That, however, the "Dalkey" of to-day is not the Dalkey of bygone times, when "ye Saxon nobles," with brazen helmet and nodding plumes, the Deputies of Majesty and Governors of Ireland, with pageant and pomp landed or embarked in her—then assumed to be—"noble harbour," it is not our purpose to advance; but that she has not kept pace with the subsequent progress of the age—that she has not been clad by the hands of man with artistic garments commensurate with her natural dignity and rank—that, in short, her aspect bears the impresse of apathy and absence of appreciation for her natural beauties, admits of no controversy. Assume her transport possible to the site of a Greenwich, a Gravesend, or a Margate, and we may, without much stretch of imagination, picture, "in our mind's eye," an altered landscape; princely mansions, lordly villas, substituted for the few usually ill-fashioned, depressed cottage structures, partly fishermen's huts—dressed to the highest capabilities of their owners' finances, on speculation "of lodgings" for the summer season—balustraded terraces and handsomely-planted esplanades, in lieu of the rough, but *not* ready, almost inaccessible "stile" approaches now in vogue. Let us hope, however, that there is in embryo a more befitting prospect; that the numerous available sites for residences will be taken advantage of speedily; and that those locally interested in its progress—the Dublin and Wicklow Railway Company especially—will offer inducements to capitalists corresponding with those in others of our suburbs.

The Dublin Builder.

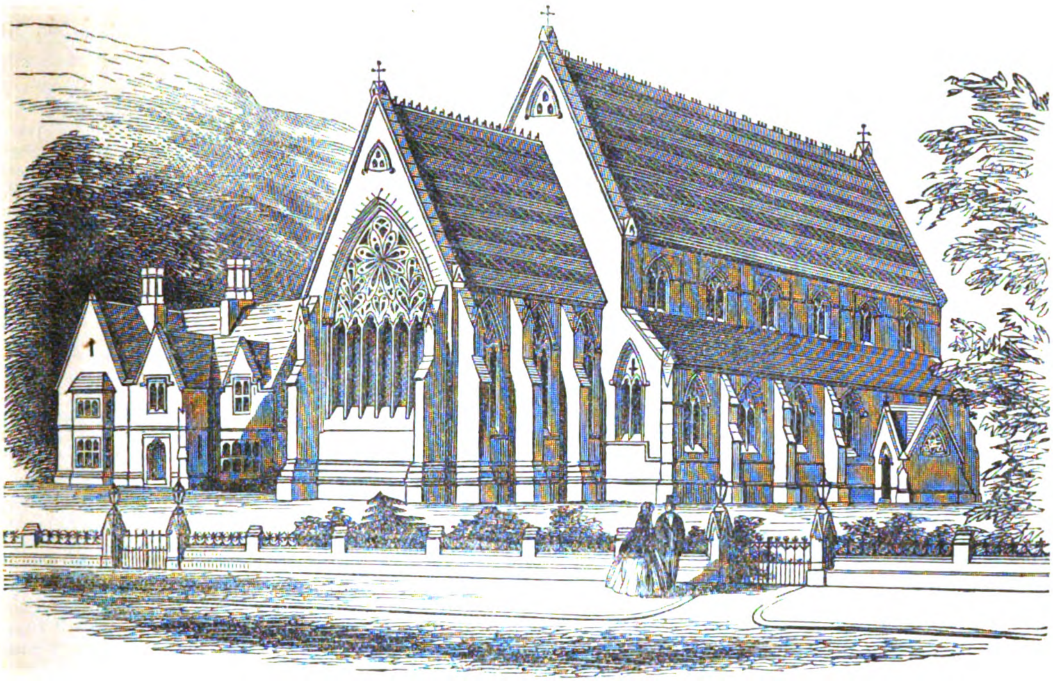
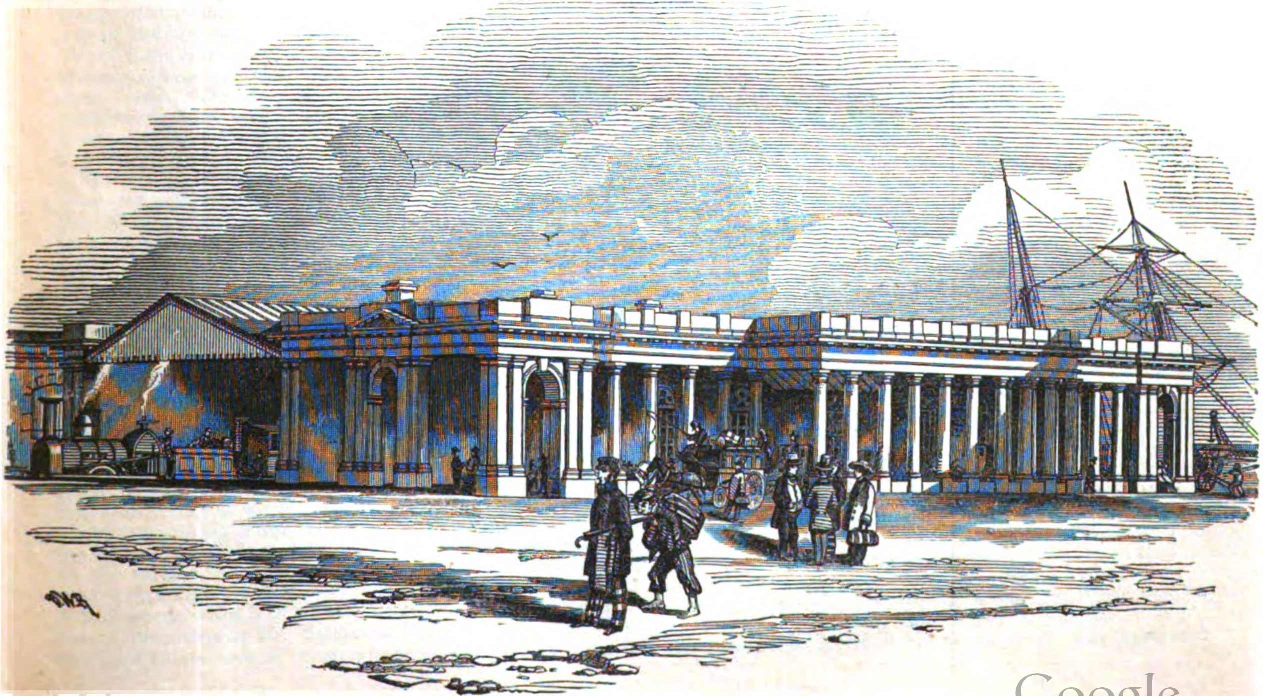
THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS



OPENING OF THE CHURCH OF OUR LADYE AND ST. MICHAEL, ABERGAVENNY.

THIS edifice, dedicated on the 15th May, is of late decorated Gothic, and consists of a nave 75 feet by 24, north and south aisles of the same length, and 9 wide, and a chancel 25 feet by 18. The nave is divided into six bays, supported by quatrefoil columns and high pointed arches, and lighted by six clerestory and six aisle windows on each side; the height to the summit is 55 feet, and it is spanned by an open timber roof, with exposed rafters, stained and varnished. The chancel is entered from the nave through a stone archway, 42 feet high. The roof of the chancel is divided into three bays by ribs springing from stone shafts, and subdivided into panels. On the northern side of the chancel are three lofty two-light tracery-headed windows, and there is a similar window on the south side. The eastern window fills up the entire end of the chancel with very elaborate and graceful tracery. The floor is laid throughout with coloured tiles. The windows are glazed with cathedral glass, with the exception of the window at the eastern end of the north aisle, which is of stained glass, from the designs of Mr. Maycock, of Clifton. It is a memorial window to the late Mr. Simon Ardus, of Abergavenny, whose widow has been the principal contributor to the building fund. It embraces the figures of our Ladye and St. Joseph, with appropriate inscriptions. The high altar is a massive stone slab, supported on three columns of polished Devonshire marble. The reredos is inlaid with coloured majolica tiles, and the decorations of the eastern wall include a canopied niche for expositions, richly carved in stone. A presbytery, with accommodation for two priests, is in course of erection adjoining the church. The material employed for the building is wall stone of the immediate neighbourhood, in random courses with Bath stone dressings. The covering is of Welsh slate, and the gables are surmounted with floriated crosses. Mr. Benjamin Bucknall, of Rodborough, near Stroud, is the architect. The builder is Mr. Henry Williams, of Broadmead, Bristol.



GREAT SOUTHERN AND WESTERN RAILWAY TERMINUS AT CORK—SIR JOHN BENSON, ARCHITECT.

(For Descriptive Particulars [illegible] 7.)

THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS

CORK.

However in accordance with the business capabilities and acumen of her citizens may be the commercial progress of Cork, a very passing glance must convince even a casual visitor, that her architectural advancement is by no means commensurate with her elementary faculties, as evidenced by the numerous gifted children of art with whose nurture her name is so universally celebrated. It is not now our purpose to conjure up the shades of her bygone celebrities—we let them sleep in peace in their earthy bed—but, after a preliminary sketch, to treat of her recent and present doings, as noted from personal observation during a brief visit. We should have been much better pleased had the task proved a more arduous one, for in truth the sum total of her improvements of any importance now in progress may be arrived at in *two* items, the one an engineering construction, the other an architectural. Without intruding upon the mission of guide-book compilers, or indulging in a romantic strain on the picturesque, we must premise, that the present deficiency of Cork, in matters of art, is more than amply compensated for by the gifts of nature, which have been dispensed to her with no sparing hand; and the panoramic beauties of her suburbs, from west to east, from Sunday's Well along Glanmire by Blackrock, Passage, and Monkstown, to the world-famed "Cove," now enjoying the more "loyal," but questionably orthodox, appellation of Queenstown, are unrivalled. While discussing the portfolio of an antiquarian and professional friend—not altogether unmindful of the accompanying good cheer hospitably provided at the former place—we enjoyed "the feast of reason," too, in contemplating the surpassing beauty of the scenery along the Dyke and the route of the meandering Lee, which here is aided by the artistic, in which the Queen's College, by Sir Thomas Deane, forms a crowning and most conspicuous feature. We must, however, regard *it*, the Lunatic Asylum, and the Sisters of Mercy Convent (designed by Mr. William Atkins, a gentleman deservedly occupying a high rank in the profession) as matters of the past with which our readers are already familiar. Comparatively so, perhaps, is also the Athenæum which we must remark *en passant* contains a noble hall, but which from the general arrangement of the approaches producing draughts enriches the local faculty after each occasion of a crowded assembly. The exterior has some classic points, but the absence of the lath and plaster superstructure would be an acquisition. Going back from whence we came—probably an Irish privilege and peculiarity—we note that one of the most important local improvements has been effected in the locality of the Great Southern and Western Railway Station, which, much to the comfort of the travelling public, and to the benefit of the city, is transformed from an awkward temporary structure at Blackpool, to the more approachable, more substantial, and more artistic building near Penrose's Quay. On another page we introduce an illustration of this neat and appropriate structure, and the following are a few descriptive particulars. The site is remarkably convenient for shipping and unloading cargoes, &c., a consummation devoutly to be wished for in all instances where practicable, and productive both of economy in time and money. The Passenger Station, with its offices, &c., consists of a colonnade of 20 Roman Doric columns, forming a covered way of 200 feet long in the centre; by this arrangement passengers are set down or taken up under the shelter so afforded. The whole of the buildings are constructed of the beautiful white limestone of the district. The offices separate the colonnade from the departure platform, and are same length as the colonnade, containing the usual accommodation of Waiting Rooms, Booking Offices, &c. The foundations of the buildings were of an expensive character, owing to the site being marshy; 600 beech piles, averaging 24 feet long, were used with concrete in this part of the works. The roof over the carriage platform is 62 feet clear span, composed of iron and timber. The cost of this building, including foundation, is about £8,000. The architect, Sir John Benson, and Mr. J. J. Bagnell the contractor.

Passing thence towards the city, we find the site of old St. Patrick's bridge the scene of busy operations, and with a pardonable inquisitiveness penetrate the paled boundary. A dredging machine—such a one as Dublin cannot boast of—is busily emptying its endless chain of buckets in clearing the foundations for a pier, and numerous masons are engaged on those partially built. One peculiar feature in their construction is, that there were no cofferdams used, but iron caissons 7 feet 6 inches high, and forming boxes for the bed of the piers were substituted. The width between the abutments of the intended bridge is 183 feet, and the number of arches three, of elliptical form, viz.—one central of 60 feet, and two of 51 feet span each. The height from the bed of the river to soffett of arches is 26 feet, and the width of the roadway at top 44 feet exclusive of pathways, total 60 feet between parapets, which will be balustraded. The entire structure is being built of the local limestone, except the first course of foundations, which is of Foynes stone. The engineer is Sir John Benson, the contractor Mr. Hargreave, jun., and the clerk of works Mr. Barnard, to each of whom we beg to tender our acknowledgments for facilities to furnish these particulars being kindly afforded. The contract is for £14,500, and it is expected that the bridge will be open for traffic in January 1861.

Seeking the site of the new Roman Catholic Church of SS. Peter and Paul, said to be in St. Patrick-street, we experience some difficulty; but at last succeeding, we exclaim, "What a place to build a church!" An important structure, too, and replete with architectural beauty, both internally and externally. Approached by a narrow laneway to its main western entrance, its southern flank parallel with the rere of the shops in Patrick-street, and completely surrounded by high buildings on all sides, some of which, if funds permit (a problematical question) may be removed hereafter, this handsome and costly edifice is now actually in progress. As we purpose giving an illustration of the interior—probably in the next number of this journal—we reserve particulars, further than that the structure will be 145 feet by 80 feet in the clear; height to apex of roof 87 feet 9 inches, style transitional Gothic, total height to top of spire 232 feet. Messrs. Pugin and Ashlin the architects; contractor, Mr. Barry M'Mullen; clerk of works, Mr. Langford. Save some preparations for the approaching agricultural show, improved market arrangements, to which we shall revert in a future No., the recently constructed water works, probably amongst the most complete and effectual in the kingdom, and a new grocery establishment in Patrick-street, Mr. Scott, architect, with a few works of private character in the suburbs, we are not aware of other subjects to chronicle in this notice. If, however, we rejoice in the soubriquet of "dear, dirty Dublin," we may return the compliment to our Cork friends, who should look more sharply to their pavement and scavenging operations.

THE MEMORIAL WINDOWS—ST. ANNE'S CHURCH.

We have already noticed the building works in progress in this Church, which may be said to have been so far completed; but there are others also on which we have not yet touched, comprising two memorial windows, a new pulpit, baptismal font, lectern, sedilia, and enclosure railing, all of very beautiful design and elaborate execution. For the present, however, we confine ourselves to the windows, but shall return to the others when accompanied by a beautiful grouped illustration now in our engraver's hands, and intended for an early number of the Dublin Builder. The windows are memorials of Knox the Reformer, and the late Mrs. Hemans respectively: the one being 21 feet in height by 11 feet 6 inches in breadth; the other, 16 feet by 7 feet 6 inches, both of Byzantine character, and executed with all the artistic carvings by Messrs. Purdy and Outhwaite of Great Brunswick-street, in an excellent quality of Bath stone, from the quarries of Messrs. Pictor and Son, of Chippenham, Wilts. This is the first Bath-stone introduced here, but there are several cargoes of it now being imported for various works, and it appears admirably adapted for ecclesiastical internal decorations.

Each window is to be filled in with stained glass; the design of that for the Knox memorial being not quite decided on, but the other, to Mrs. Hemans, is daily expected from Mr. Warrington's establishment, London.

PROPOSED PROVINCIAL EXHIBITIONS OF THE ARCHITECTURAL PHOTOGRAPHIC ASSOCIATION.

We learn that overtures have been made to the Committee of this Association by some professional gentlemen in the provinces, for the purpose of securing an exhibition in their respective towns of a collection of photographs; and furthermore, that the attendant expenses would be guaranteed. How far negociations may have privately progressed towards this end in the Irish provinces, we are unable to say, but as yet no step has been taken as regards Dublin. That the exhibition would prove most instructive and pleasing, as well as be very extensively appreciated by the members of the architectural profession, is a certainty; but we would infer, that it is a *sine qua non*, that a local committee should indemnify the Association against loss, and here arises a difficulty. We apprehend that few of our local professionals would be disposed to undertake the responsibility—however nominal it might virtually be—finding their time and attention fully occupied by their ordinary avocations; but, if we might offer a suggestion, the Association would probably experience no difficulty in obtaining from some one of the Societies here identified with the advancement of art, permission to occupy their galleries for a limited period, a small fee being charged to the public for admittance; and the proceeds, after deducting advertisement, carriage, and other expenses, to be disposed of as may be mutually arranged.

We anticipate that the important accession of members for the ensuing year, would very amply repay the committee any extra trouble incurred, provided that a creditable display be secured.

THE DE VESCI TESTIMONIAL AT ABBEYLEIX.

SOME time ago the designs of Mr. John S. Butler, architect, of Hume-street, were selected for the above testimonial, although the committee had previously awarded to a Mr. Crofton a premium offered in competition, and the structure is now being carried out. In a recent number of the *Agricultural Review* we find the following, accompanying an illustration of the structure:—"The committee of this memorial of a true 'Irish country gentleman,' deserve every credit for the happy conception. The memorial will not be a mere useless heap of stones, but, combining the useful with the ornamental, will be a sanitary boon to the inhabitants of the town, and contain an open reservoir for water, from which the thirsty cattle may "drink deeply." From the centre of the reservoir rises a handsome structure in the Italian style, enclosing a water tank from which the basin is supplied; and, we believe it is contemplated to run a pipe from this tank under the flagging of the basin, and from thence to the houses of the inhabitants of the town. The testimonial will be twenty feet square, and twenty-five feet in height, will be of limestone, and promises to be in beauty second to no similar structure of the kind in the United Kingdom. The cost is not to exceed £225, and how so beautifully decorated a structure could be erected at so insignificant a cost is truly marvellous, and leads us to hope that many of the streets and squares of our city should be provided with ornamental fountains, be they of a *testimonial* origin or otherwise. Mr. John Rafter, of Rosenallis, is the contractor."

KERFS AND COGITATIONS.

BY A CRAFTSMAN.

NO. IV.—DEAD MEN!

START not, reader! our title may be ominous, but we speak metaphorically. Though inclined to a "kerf" betimes, the scalpel is not the instrument of our incision, nor the grave the scene of our investigation. In crowded city, in busy workshops, on Queen's highway, our subjects are legion, our material is at hand. Young, stalwart, and seemingly endowed with all the physical attributes of ordinary members of society, are myriads of our youth, drawling "dead" men—mentally "dead" to all high endeavours, noble impulse, or individual exertion. To incite them to a sense of their position, to present incentives for their study and advancement, to guide them to the goal of honour and distinction, are the objects of our mission; be theirs the ambition to follow on. Each man, though dissimilar in taste to his fellow, can try his hand at something; and by persevering application, combined with even moderate ability, may succeed in carving an indelible imprint on the mind of his age. Who, then, ought to hesitate, at least to tread on the threshold of a career open to all? To young men in the mechanical departments of the Architectural, Engineering, and Building professions, we would specially address ourselves; and remind them that there is no lack of ability amongst their fraternities, although each and every of them have had their energies and skill taxed, and creditably so, to a large extent in working out architectural intricacies and complex construction; that they live in an improving age—that they must not be content because they can do as well as their fathers, but travel in an onward direction, and invoke science to aid them in their handicraft. But the pursuit of science is a bugbear to many, sufficient to scare them, though from her recreative fount may be imbibed stimulating influences and prolonged sensations of pleasure. Opportunities innumerable present themselves on every side to anxious and willing hearts, ready to burst the degrading fetters of apathy that bind them mentally and physically. Awake, then, from your lethargy, Craftsmen! spurn idleness and laziness, with all their degenerating concomitants; take pattern from the example set you by a Stephenson, a Watt, a Soane, a Britton, and others, who worked in the ranks at the rising of their sun, but who, by dint of application during the ensuing morning and day, found themselves at its setting in the evening placed in the foremost van of fame and fortune.

C. C. H——Y.

THE WESTMINSTER CLOCK.

THE origin of such an idea has now passed from our recollection, but we have at some time been under an impression, that had not the first "Big Ben" succumbed as it did, it must yet have continued to lie at the foot of the Clock Tower; but perhaps many of our readers may remember, that the second bell was of an altered form and less in height than the first, that it was laid on its side while being hoisted, and that it was still understood to be as large as the inner well of the tower would admit.

The tone of the present bell was never to our ear strictly agreeable, but always induced the opinion that more was expected than it was able to perform, that the blows were too heavy, and instead of a rich and mellow tone, a jarring harshness grated on the ear. Nevertheless we received with deep regret the intelligence of its early fracture, and have passed with feelings closely allied to melancholy under the shadow of the beautiful campanile from which it no longer resounds.

Mr. Cowper lately told the House of Commons that "he was consulting men of high scientific attainments," so that until the result of their experiments be known it will be impossible to form a definite opinion on the possibility of renewing its tone without recasting. One thing seems to have been ascertained, namely, that the hourly notes of such a stentor were very inconvenient to members, and both they and the public will be the less impatient on the subject after the first Commissioners' statement, that it has been determined to make a temporary substitute of the largest of the four quarter bells (which he tells us is as large as that of St. Paul's) for striking the hours, and leaving the remaining three for their original purpose. Should this trial of the smaller quartette prove successful, the great bell may hang a silent though not "a faultless monster," if indeed the term may be provoked by any English bell, when those in other countries, and especially Russia, are so very much larger; but the choice of situation was certainly somewhat extraordinary, for recollecting as we do a notice in the Reading room of the British Museum—"Silence is indispensably necessary in a place devoted to study"—we should have thought stillness suited to objects of deep deliberation.

The fracture of "Big Ben" is likely to be attended with ultimate advantage to science from the attention it has aroused on the subject of the amalgam for bell metal. It commonly contained four parts of copper and one of tin; six parts of copper to one of tin proves stronger; but the alloy used at Westminster was in the unusual proportion of one part of tin to three only of copper, and besides this apparent weakness of composition only was the error of making the hammer on a more than usually heavy scale.

DUNKERRON CASTLE.*

BY JOHN WINDELE, ESQ.

NEAR the head of the estuary or bay of Kenmare (Hibernice, *Ceann Mara*), in the county of Kerry, stand all that remains of this once important fortalice.

The few ancient notices which we possess, supposed to refer to this great inlet, are subjects of doubt and conjecture. By some it is believed to have been the *Inbher Sgeine* of our native writers, and either the Iernus or Iuvernia, or the *Dur* of the geographer Ptolemy. But Camden supposes that the *Dur* was the rivulet flowing into the bay of Tralee; whilst Dr. O'Conor, after Ware and the historian Smith, assigns it to the bays of Castlemain and Dingle. Dr. Graves gives it to the bay of Kenmare, at whose entrance lies the island of *Dur-sey*. Nevertheless, the opinion may be worthy of consideration which would identify the *Dur* with the *Cuan-dur*, or Glandore Harbour, in the south-west of the county of Cork. The name is certainly indicative of our early Iberian descent, and of the sunny regions watered by the Durius or Duero. . . .

Dunkerron Castle, a massive vaulted structure of the "Tudor" era, occupies the site, as its name implies, of an ancient dun or fortress, constructed ere the introduction of castellation into Ireland. It is distant about two miles from the modern town of Kenmare. In its present condition it is a greatly shattered, but not unpicturesque ruin, standing close by the shore, within a small demesne, and environed by recent plantations. Its southern side has entirely fallen, carrying with it portions of the eastern and western walls. Originally a vaulted tower or keep, it was ascended by flights of stone stairs in the thickness of the walls. Its great arch, contrary to the usual practice, instead of being placed in the upper part of the building, formed a basement compartment, at about one-third of the whole elevation from the ground. The greater portion of this vault has also been destroyed, leaving only a mere fragment of it remaining.

At a short distance from its south-east angle stands the high-pitched end wall or gable of a far more recent mansion, belonging to the Transition period, succeeding the reign of the first James. It retains its capacious fire-places and mantle-pieces, but no other feature worthy of notice. The whole structural group, although not without picturesque effect, has never yet found any published or engraved illustration, nor has it received the charitable vesture or drapery of mantling ivy, so seldom withheld from our old warrior or religious piles. No doubt, tradition and legend have been associated with its story, and reminiscences of its past days may still survive in the folk-lore of the neighbouring peasantry; for its ancient lords were of a stirring and daring race, who limited not their operations to the adjoining plains and mountains; their galleys traversed in search of adventure, glory, or traffic on the open seas which lay around, frequently visiting the ports of the Saxon and the Gall, or those further to the south, remembered as the original home of their distant forefathers; but of these recollections we have noted none, and must leave their collection for some future gleaner.

---

* Read before Kilkenny Archæological Society, and published in Transactions.

The O'Sullivan More, to whom this castle and the wide-spread domains which once appertained to it belonged, was the head of a powerful "*Eoganacht*," or "Eugenian" tribe of the same royal *Heberean* race with the Mac Carthies, the common ancestor of both families being Aedh dubh, King of Munster. This prince had two sons, Finghin and Failbhe Flan, who severally succeeded him in the provincial sovereignty. From Finghin descended, in the eighth generation, Eochy, son of Moal Ughra, who received the soubriquet of *Sullivan;* whilst Failbhe was the ancestor of *Cartha*, each of whom gave the family surname to his posterity.

The derivation of his denomination of Sullivan to Eochy is the subject of a pious but, nevertheless, rather improbable legend. It happened that an Albanian Druid, named *Labhan*, in the course of a speculative tour in Ireland, visited this prince, then residing at his ancestral moat of Knockgraffon, in the present county of Tipperary. Delighted with his poetical and musical art, Eochy desired him at his departure to name the reward which he chose to receive. "Your two eyes," said the rapacious and malevolent old pagan: and Eochy, holding in special regard his own good name, and fearing, beside, the poet's satire, gave them to him. St. Ruadhan of Lothra was at that time on a visit also at the royal moat; and, justly incensed at what occurred, he prayed that the eyes of Labhan should be transferred to Eochy, instead of those he had lost. His supplication was heard, and the prince, thus "recouped," received thenceforth the name of *Suil-Labhan*, that is the "eyes of Labhan." When patronymics came to be adopted in Ireland, in the reign of that "Star of the Field," Brien of the Tributes, at the close of the tenth century, Buadhach cro, the grandson of Eochy, assumed the soubriquet of his grandsire, and transmitted same to his descendants. . . .

The Cappanacuss O'Sullivan was seated a few miles to the west of Dunkerron. His stronghold was a narrow "peel house" or castelet, most unpretentious in its architectural features. This building still braves the tempest and the breeze within the demesne of Dromore, near where the Kerry Blackwater joins the bay of Kenmare, after emerging from one of the most picturesque scenes to the south of Killarney, at Blackwater bridge. The O'Sullivan of Cappanacuss, in default of male issue to the O'Sullivan More, succeeded to his inheritance as next in seniority. It is said that the O'Sullivan of Dunloe (Tomies), was in the last century the representative of these two houses, but no authority for this appears.

The O'Sullivans, who took the name of Mac Gillicuddy, are still represented. They assumed the latter appellation in honour of their patron saint, and the family still enjoy rank and position in their native country. The present "Mac Gillicuddy of the Reeks" resides in his paternal mansion at Whitefield, at the base of Carn-tuel, near Killarney, and traces his pedigree to *Giolla Mochuda caoch*, son of Donal More O'Sullivan, of Carrigfinvoy. Connor, the son of Giolla Mochuda, is recorded by the Four Masters as having been slain by his own kinsman in 1411. . . .

The Castles of Carriganass, Dunboy, Reendeeshart, Ardea, Dunkerron, Cappanacuss, and Dunloe still survive in more or less preservation—the last alone now habitable, the others utterly ruinous—monuments, however decayed and fallen, yet attesting the former power and importance of a high and chivalrous race, whose proud boast was expressed in the well-known—

> "Nulla manus tam liberalis, et generalis atque
> Universalis quam Sullivanus."

Tradition states that, at the time of the Revolution, Dunkerron Castle was held by Mac Carthy Reagh. The late Maurice O'Connell, son of the great Tribune, has left some spirited lines on the fall of the last chieftain of the Mac Carthy race who held this structure, and who, with his nephew, was killed at Aughrim. This poem commences:—

> "On high Dunkerron's battlements the slanting sunbeam falls," etc.,

Eoghan, who died in 1687, left a son, Daniel O'Sullivan More, who married Hester O'Sullivan. He died on April 16, 1754, without issue, and his widow survived him until 1796. Both were buried in the monastery of Oirbealigh, or Irrelough (Mucross), the ancient burial-place of the race, as well as of the O'Donoghues, &c.

Until within a few years the sculptured stones, of which Mr. Du Noyer has furnished the Society with the faithful and graphic drawing appended to his article, lay in a boat-house attached to "Lansdowne Lodge," near Kenmare, during the occupancy of Mr. Pelham, a former agent of the Shelburne estates. They were subsequently removed to Dunkerron, where I saw and took rubbings of them; since then they have been placed, surrounded by mason-work, in the wall of the more recent ruin, near the original building, where they are now, it is hoped, safe from injury. They formed portions of a carved chimney-piece in the original structure, although not coeval with it. Crofton Croker has given copies of the arms and the inscription in his "Fairy Legends," and the latter was also published in "Notices of Cork and Killarney," and again in the "Transactions of this Society," the late Mr. Hitchcock in his fastidious love of minute accuracy, deeming a typographical error in the "Notices" sufficient justification for a republication!

The shield of arms suggests a few observations. The blazoning is totally different from that in use by the O'Sullivans for the last two centuries, which is, according to the heralds, "Per pale, vert and ar. on the first a buck pass. ppr. on the second, a boar pass. per pale, sa. and ppr. On a chief or, two lions, ramp. combatant, gu. supporting with the fore paws a sword entwined with a serpent. · Crest, on a ducal coronet a bird ppr.

Motto, "Lamh Foistenach an Uachtar." In Harris's "Ware," p. 164, their war-cry is given as "Fustina-Stelly-aboe," whatever that means.

To me the Dunkerron shield and its charges has a very Arkite expression, and seem quite a mythological composition. The latter appear more or less connected with the legendary lore of the family. Differing so entirely frem all the recognised rules of heraldry in the sixteenth century, we may presume that in the blazoning the artist must have taken his instructions from the hereditary Bolsaire or Seanachuidhe, full of traditional recollections of the race, or had used "emblems and devices, which had previously existed beyond the memory of man." . . .

O'Halloran tells us that at Tara the esquires of the nobility presented themselves at the door of the grand hall (Miodhchuarta) and gave in the shields and ensigns of their different masters to the deputies of the great Marshal of the Crown, and, by direction of the King-at-Arms, they were ranged according to the quality of the different owners. Dermod O'Connor, the translator of Keating, had, several years before O'Halloran wrote, published a statement somewhat similar, an interpolation on the text of his author. But neither in the poem of Eochaidh O'Flinn, descriptive of this great banqueting-hall, nor in that of Keneth O'Hartigan, who was contemporary with O'Flinn in the tenth century, and to whom Dr. Petrie refers as the sole authority from which writers have drawn their accounts of the magnificence of Tara, is there the slightest reference to armorial insignia. But we have in Keating, and it is to be found in every copy of the original manuscript of that writer which I have seen, although his translator O'Connor has altogether omitted it, a passage since published by Dr. O'Donovan, informing us that the clans carried with them into battle distinctive military ensigns of various colours and textures. These were as necessary, certainly, to them, as rallying-points, as their characteristic war-cries or shouts. The evidence of this fact is drawn from the ancient account of the battle of Magh Ryth, fought in A. D. 637, between Domhnall, King of of Ireland, and Congal Clean, King of Ulahd. Here we find the contending armies marshalled under ensigns of different colours, each king having his own standard (Meirge), "great symbol of plunder, floating from its staff," and charged with emblematic devices. Such was the banner of Congal, the King of Ulster:—

> "A yellow lion on green satin
> The insignia of the Craobh ruadh,
> Such as the noble Conchobhar bore."

Keating, referring to this statement, derives the practice of distinguishing by banners, which prevailed from the earliest times, from the example of the Israelites, in their Exodus from Egypt, when each of the Twelve Tribes bore its blazoned standard, as the Tribe of Reuben, the Mandragora, &c. Indeed, we are expressly told in Numbers, ii. 2, that the Israelites carried with them standards "with the ensigns of their fathers' house" upon them.

But although the clans were thus distinguished, we have no evidence of armorial bearings or escutcheons in the sense of modern heraldry. O'Flaherty, in "Ogygia," citing Bartholemeus Cassaneus, describes the insignia of Ireland as a golden king enthroned in majesty, holding a lily on a black field, but no date is given. Dr. O'Donovan gives positive testimony against their use by any Milesian Irish family before the reign of Elizabeth, and avers that the Irish families "first obtained the complex coats of arms which they now bear from England, retaining on the shield, in many instances, those simple badges which their ancestors had on their standards, such as the red hand of O'Neill, the cat and salmon of O'Cathain, or O'Kane, &c. &c., with such additions as the King-at-Arms thought proper to introduce, in order to complete the escutcheon after the Anglo-Norman system of heraldry, according to the rank of the family for whom the coat was manufactured."

Elsewhere (p. 350) the learned Doctor says:—

> "The armorial bearings of the old Irish families, as preserved on their tombs since the reign of Henry VIII., if carefully collected, would throw much

light on the kind of badges they had borne on their standards, previously to their adoption of the Anglo-Norman system of heraldry."

In these opinions of this justly esteemed scholar and antiquary I fully concur. The few shields of arms belonging to the Milesian race which I have seen and examined at Inis Cailtre, Roscommon, Mucross, and elsewhere, are all blazoned in this Anglo-Irish style, and evidently belong to a recent age. Indeed, it is highly probable that before the entire submission of the native Irish, temp. Elizabeth, those proud chiefs, who had so long sought to maintain their independence, refused to accept or to imitate the herald's art, as organized in the English school.

Correspondence.

THE LATE TRIAL OF MILNERS' AND PRICE'S SAFES.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR—The report of the late test of safes at Burnley in your journal of the 1st inst., copied from the *Liverpool Courier*, is so full of inaccuracies and wilful mis-statements, that I hope, as an act of justice to me, you will not only allow the following corrections to appear in your next publication, but will also, if your valuable space admits, print the evidence given on oath before the Coroner, which will, I trust, counteract the injury intended to be done me by the erroneous and partial report above referred to.

Before the tests commenced I delivered an address to the assembled crowd, from which the following is extracted :—

" In resuming the test of my improved Double Patent Fire and Burglar-proof Safes, I think I can say but little more in explanation of the cause of the postponement from the 16th to the present day, in addition to what I stated in my letter to Mr. Denbigh, and which has been published in the *Burnley Advertiser*. A short time previous to the 16th I had introduced an improvement into the construction of my 'Ne-plus-ultra' Safe Door Lock, for the purpose of making it stand *repeated* charges of gunpowder, but instead of making new safes for the *new* locks, I had the locks removed from two *old* safes that had been made before I used my patent steel nozzle keyhole, and put my improved locks on in their place; but unfortunately, the time was so short, and the week being Easter week, the two safes were finished late at night, after my manager and myself had left the works, and the consequence was that the men omitted making good the space between the nozzle and the front door-plate, so that after the small lock had taken in all the gunpowder it would contain, the further supply of gunpowder found its way, through the space before mentioned, *into the lock-chamber* when, rather than run an unfair risk, I thought it better to postpone the test till a future day. Accordingly I am here to-day for the purpose of submitting a specimen of my Case-hardened Fire and Burglar-proof Safes to the most severe tests that can be applied, whether with drills, chisels, or gunpowder, in order to prove, not only that my safes are really drill-proof and gunpowder-proof, but more particularly, that they are the only ones that are so."

With respect to the £50 challenge at the first test, as no one accepted it, a mechanic, at our request, put the powder in the lock, and it was not till after I found that there was some unaccountable error in the construction of the nozzle and nozzle hole, by the gunpowder still disappearing, and when I declined, for the reasons stated, to have the safes fired, that a word was said about the £50. That the challenge was never accepted is proved from the fact of no one having offered to deposit their £50, so that there was an end of it.

I never announced that the safe to be operated upon at the resumed test would be " a new safe made for the occasion," and the fact is, that the safe that so valiantly withstood all the extraordinary and determined efforts of Milners' representatives and assistants at the last test, was the same identical safe that was there at the first test, and which then withstood every effort to bore it with a powerful ratchet drill.

The safe of Milners' was purchased the Monday previous as a *very best* Milners' Safe, with a " powder-proof lock and *bolt-chamber*," and containing all Milners' improvements, and which is further described in their price-list as being " drill-proof."

It was Messrs. Milners' mis-statements with respect to all other makers' safes, and their advertising their safes as being " drill-proof," and as having *powder-proof bolt chambers*, that caused me to take the course I did to prove the contrary, and I can open any of Milners' quadruple Patent Safes in the same time as I opened the one at Burnley, viz., 18 minutes, thus proving them to be *neither drill-proof nor powder-proof*.

The lurry containing the other safe which Milners' people brought into our enclosure, threatening violence to the police if resistance were offered, was simply a trick to call attention from the one I was about to operate upon, and which I have since been informed had been really made on purpose only the week befere, and was constructed with a solid half-inch plate of steel at the back of the door. If the safe I opened was an old one, what in the name of reason do they call a new one? It was represented by Mr. Davis and his assistant as being one of Milners' *very best*, and which is stated to be such on the invoice. It answered to their own description, and had their " Phœnix escutcheon " over the keyhole, the very thing that Milners themselves say, in their advertisement " Renewed Caution," is the proof of such being genuine and containing *all* their improvements. The lock was one of Hobbs's made powder-proof upon Milners' double patent. No. on the lock 40,014, and on the keys 66,864, with a steel plate over the lock ; the lock-chamber had the wooden filling in, and a piece of steel (which they call the " door attachment," I suppose) let into the wooden packing over a portion of the large bolts. The certificates published in your last number will prove the truth of the above statements ; and the evidence of Mr. Roberts, from whom the old safe of my manufacture was bought, will prove that it was sold to him in Feb. 1856 ; that it was fitted with a Chubb's lock ; and that it was well known by all parties concerned not to be powder-proof.

My success was so complete—my own safe standing everything, while Milners' stood nothing—that it seemed to drive Milners' representatives to madness and desperation, or they would never have exploded *an old safe with an open lock-chamber* with such an enormous quantity of gunpowder. Before this took place, my agent, my assistants, my property, and myself had left the ground. It was entirely the affair of my opponents, and they have had to compensate the father of the poor boy that was killed, with £15 5s., and will also have to do the same to the man who was so badly hurt.—I am, Sir, your obedient humble servant,

Wolverhampton, June 11th, 1860. GEORGE PRICE.

FREE TRADE IN STONES.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR—As one of your oldest subscribers may I take the liberty of asking you if ever, in editorial phraseology, you met before with any statement relative to " *Free Trade in Stones?*" It strikes me the question would embarrass all modern free-trade reformers, even the late "Joe Hume," or " Richard Cobden " himself. I shall therefore not press it, but explain my reasons for this communication. Referring to a recent case at petty sessions in this town, wherein some parties summoned Mr. Michael O'Brien, the manager for Mr. Thomas H. Carroll, of Dublin, the proprietor of an extensive quarry here, "for having built a shed across the road to plaintiff's quarry, thereby preventing ingress and egress, and for permitting a quantity of gravel and stones to remain in the face of the quarry, thereby preventing its being worked," the editor of a local journal, the *Western Star*, thus concludes his report of the proceedings :—" It is to be hoped that the decision in this case will in future produce *free trade in stones*, an article so abundant in this neighbourhood, and by the abolition of the monopoly which has existed for some time, facilitate those who, in the present progressive state of Ballinasloe, are engaged in the erection of new buildings." Now, as regards the wilful obstruction, that is a matter with which I have nothing to do, though I may state that Mr. Carroll is known to your readers to be too respectable a man to connive at any illegitimate proceeding. But in the reference to " monopoly," as *I* am included—without mention of name—being also the owner of a large quarry in the town, I must say that I pursue my business independently of any of my neighbours; and if a man, in a fair spirit, seeks to forward his own interests and push a trade, I do not see why it should be designated " monopoly."

Trusting you will excuse my trespassing on the space of your excellently-conducted and highly popular journal, I remain yours,

Ballinasloe, June 20, 1860. FRANCIS MADDEN.

Notes of New Works.

LOCAL WORKS.

The War Department are about having some roofing works executed at the Military Stores, Montpelier Hill.

A new Church, to accommodate 300 persons, is to be built at Dollymount. The style will be Gothic. Mr. Rawson Carroll, architect.

Three villas and offices are to be built at Ovoca Avenue, Blackrock. Mr. E. Carson, architect.

Two villas are in course of erection at Leeson Park, in this city, for Messrs. Colles, and G. W. Shannon respectively. Mr. R Carroll, architect; Mr. Dwyer, builder.

A private School-house is to be built at Rathmines. Mr. D. C. Ferguson, architect.

New Turkish Baths are in course of completion at Upper Rathmines, similar in principle to those already described in this journal, but on a much smaller scale. The front towards the road is Orientally architecturized, as far as limited site would permit.

"Wave Crest" houses on Bray strand, recently enlarged by the addition of another storey, are now fit for occupation. Mr. Lyons, architect.

A mansion and offices is to be built at Earlsfort Terrace, according to plans, &c., by Messrs. Lanyon and Lynn, architects.

We understand that extensive alterations are being made in the offices of *Saunders' News-Letter*, prior to proposed new arrangements. Mr. Charles Papworth is the architect; Mr. William Hughes the builder.

The new Roman Catholic Church at Raheny is progressing, and Lord Howth has given a donation of £25.

It is proposed to enlarge Killiney Church, which is said to be "insufficient for the growing requirements of the neighbourhood."

The foundation stone of the new Molyneux Church and Asylum was laid by His Excellency the Lord Lieutenant, on the 11th ult. Particulars and illustration of these buildings may be found by reference to April number.

The city basins or reservoirs have been for some time in process of cleansing, and a quantity of alluvial deposit and noxious spongilla taken therefrom.

PROVINCIAL NOTES.

The new Church of St. Mary's, Athlone, already referred to in this journal, is in course of construction, after designs by and under the superintendence of Mr. John Bourke, architect. The contract for the plastering has been taken by Messrs. Hogan and Sons, of Dublin. All the mouldings round the arches, separating the nave from aisles and chancel, are to be in Portland cement, and the walls throughout to be lined in Ashlar courses, to imitate Portland stone. This building, when completed, will be one of the most important parochial churches in Ireland.

Sundry works connected with the supply of gas to the town of Roscommon are to be executed. Time for tenders to 7th instant.

Tenders are invited for the building of a School-room at Ballinamore, county Leitrim.

The Church of Drumcliffe, Ennis, is to be rebuilt, and the churches of Billis, county Cavan, and Drinagh, county Cork, are to be enlarged by the Ecclesiastical Commissioners. Tenders till 7th instant.

A new passenger station is to be built at Dublin bridge, Newry, for the Newry and Warrenpoint Railway Company. Mr. Richard Hassard, C.E.

A new Railway Hotel is in progress of erection at Kinsale, after designs by Mr. Conybear, C. E. It has a principal front towards the river. four storeys in height—up two of which are carried oriel windows—is in the Italian style of architecture, with main cornice and frieze, ornamented with brackets, and surmounted by a balustraded parapet. From a spacious terrace in front, access is obtained by flights of steps to ladies' and gentlemen's floating baths, and to the various wherry craft that ply upon the river. Mr. Barnard is the contractor. About 5,000 cubic yards of rocks were excavated for the foundations.

Alterations and additions are being made to Geashill Castle, near Tullamore, for Lord Digby. Mr. R. Carroll, architect; Mr. Millard, contractor.

Various works in the restoration of Ardavillage, county Longford, for Dowager Lady Fetherston, are being executed. Mr. R. Carroll, architect.

The foundation stone of the new Church at Clonea, county Waterford, was laid on the 10th ultimo. It will be in the early decorated Gothic style, consisting of chancel, nave, side chapels, aisles, sacristy, and porch, the essentials of a parochial church. The tower and spire are not for the present intended to be proceeded with. The interior of the church will be 116 feet in length by 54 in breadth; the external walls 17 feet high, and the clerestory walls standing on the pillar arches 38 feet in height; from the floor to the apex of the roof, over about 63 feet. The chancel arch will measure 43 feet to the keystone. There will be five open archways at each side, separating the aisles from the nave, and also dividing the side chapels from the chancel and aisles. The pillars, arches, jambs, arches of windows and doors, groins, weatherings, stringcourses, barges, crosses, eavecourses, &c, are to be of Bathstone; the two east and west windows containing very beautiful tracery; the windows of the clerestory and south aisle, divided into two lights, will also have tracery heads. The ceilings of chancel and lady chapels will be panelled and decorated; and the other roof ceiled between rafters. The entire woodwork throughout richly stained and varnished, and elegantly wrought crosses in stone will surmount the different gables. The sashes will be of lead, glazed with cathedral glass, and the door furniture of superior quality. Mr. J. J. M'Carthy, architect; Mr. W. Pierce, contractor. Amount of contract between £5,000 and £6,000.

The plans for effecting the required alterations, to convert the House of Industry at Clonmel into a Lunatic Asylum, as designed by W. H. Deane, Esq., C.E., have been highly approved of, and have received the sanction of the Board of Works.

The new Church of St. Bridget, at Blanchardstown, is to be completed, and contributions are being received for that purpose.

Upwards of £500 have been subscribed for the erection of a cornstore, for the accommodation of market buyers at Thurles. Viscount Jarnac will erect another at his own cost.

A station-house and goods-store are to be erected at Cootehill, county Cavan, for the Dundalk and Enniskillen Railway Company. Mr. William Murray, architect. Tenders to 4th inst.

Tenders are required for altering and enlarging Clonea House, Dungarvan, county Waterford. Mr. J. M'Curdy, architect.

Turkish Baths have been recently erected at Lismore Castle, as also at Dromona, Co. Waterford, the seat of Lord Stuart de Decies.

Alterations and additions are to be made to the County Court-House, Armagh. Time for receiving tenders limited to 2nd inst.

The Churches of Kilgarvan (Co. Kerry) and Tullylish (Co. Down) are to be re-built, and those of St. Michael's (Blackrock), Kilgariffe (Clonakilty) Co. Cork, and at Mullingar, are to be enlarged according to plans by the Ecclesiastical Commissioners Architect.

A new bridge is to be erected by the Board of Public Works across the river Lagan at Ormeau, near Belfast. Time for tenders limited to 10th inst.

The Lighthouse Commissioners have resolved on erecting a lantern on the tower at westward end of Bere Island.

A new Church is being erected at Taghadoe, early English in style with nave and chancel 100 x 26; vestry at south side, and tower and spire at north-west angle of nave, Mr. J. J. M'Carthy, architect, Mr. Beardwood, contractor. Expenditure under £2,000.

At Killorgin, county Kerry, a new Church is also to be erected, comprising nave, aisles, transept, chancel, side chapels, tower and spire at south-west end in the decorated style of Gothic. Mr. M'Carthy, architect.

New Churches, in the Gothic style, are to be erected respectively at Dingle and Fieres, Co. Kerry. Messrs. M'Carthy and O'Connell, architects.

The Marquis of Downshire is making extensive additions to his Marine residence at Dundrum, county Down.

RAILWAY MATTERS.

The Board of Public Works opposed the extension line from Kells to Oldcastle, in consequence of a level crossing being introduced at Kells. The promoters allege, that "there is no great traffic at the point, that accidents would be unlikely, the line only being a single one and every train would stop at the station," also, "that the alternative to the level crossing would be to raise the carriage road fifteen feet, at a sudden incline, which would be very inconvenient to the town," whereas the opponents believe that the proposed crossing would be attended with damage to life, and that trains approaching should come down a circuitous incline for some distance before arriving at the platform, and that there is nothing to ensure that steam would be shut off in proper time on all occasions. The committee overruled the objections, and allowed the level crossing.

The Royal assent has been given to the Newry, Warrenpoint, and Rostrevor railway bill.

The Directors of the Dublin and Wicklow Railway have acceded to the wish of the inhabitants of Sandymount for a station, and the necessary works are being proceeded with.

It is proposed to construct a single line of railway from Goold's Cross to Cashel, forming a junction with the Great Southern and Western Railway, at the former station.

Reviews.

The Temples of Arcadia. London: John Weale, High Holborn. 1860.

IT is not often that an architectural book of the very highest pretensions beams upon us. Pre-eminence of subject may be assigned to original conception, but secondary to such alone, are the faithful and artistic representations of works of classic interest, monumental importance and venerable antiquity. Great was the enjoyment recently derived from looking over the illustrations of architectural design, polychromy, constructive details, sculpture in its true accessorial form, each figure free and unrestrained in itself, yet composed with such direct reference to its destination, as to invest the *en semble* with a striking accordance and unanimity of sentiment, which Professor Cockerell's book contains.

Neither is it often that a purely artistic love will draw from his leisure, or attract from his busy avocations one with varied powers so marvellously concentrated in the President of the Institute of

Architects. Long, long may he continue to bear his blushing honors, of which some are recorded on the title page of his work, while those of greater value reside in the sentient repositories of many hearts.

The title in full is subjoined.

"The Temples of Jupiter Panhellenius at Ægina, and of Apollo Epicurius at Bassæ near Phigaleia in Arcadia, by C. R. Cockerell, Professor of Architecture in the Royal Academy; Member of the Institute of British Architects: London. Honorary Doctor of Civil Law: Oxford Member of the Dilettante Society. Associated member of the Institute of France, and Chevalier of the Legion of Honour. Member of merit of the Academy of St. Luke: Rome. Foreign member of the Academies of Munich, Copenhagen, &c., &c., to which is added a memoir of the systems of proportion employed in the original design of these structures by William Watkiss Lloyd."

Country Cottages. By John Vincent, architect. London: E. & F. N. Spon, Bucklersbury.

So few works of any merit referring to domestic architecture have as yet issued from the press—though albeit, the alleged efforts for its improvement have been very numerous—to our mind unhappily so for the cause of art and the good of the public generally—that we approach with some distrust *any* work professing such a purpose. Convinced, however, that as wide a field is open in this department as in the various others wherein standard works of unquestionable excellence have been produced, and that still an important mission remains to be fulfilled, we cast aside what some may probably denominate fastidiousness, and with an unprejudiced eye examine the newly published claimant to favour before us.

Without "judging the book by its cover," or further, without assuming that the lithographers and the printer's skill, displayed to a very meritorious degree, impart intrinsic excellence; we must, nevertheless, in those—not unimportant—departments, award a meed of praise to those concerned in their production. The author has aimed evidently at a double purpose, the pictorial and the practical, though in the former with questionable prudence, as either he or his artist have drawn somewhat *too* largely on his imagination for landscape effects, leaving inquisitive minds to meditate upon the probable merit of the "Architectural" in such localities where luxuriant foilage, gentle slopes, meandering rivulets, and other accessory natural beauties might not be present. To the designs, which are generally tasteful externally, and well-arranged internally throughout—save where W. C's. are introduced under the main roofs, a decidedly objectionable disposition even where the most effectual apparatus is within reach of the proprietor's pocket, which cannot be assumed probable in this instance—we must take one exception—viz., precise suitability in some regards to the domestic requirements and pecuniary ability of "agricultural labourers." The table of labourers' wages in twenty-nine English counties introduced into the work, shows the highest average to be 16s. 6d. (Westmoreland and part of Yorkshire), and the lowest from 8s. to 8s. 9d. per week (Berkshire, Devonshire, Dorsetshire, Essex, Gloucestershire, Herefordshire, Suffolk, and Wiltshire); but even liberally assuming the mean average earnings of the labourer throughout the kingdom to be 13s. per week, those of the wives—where such are—being placed as sets off against the support of helpless children, the portion for rent which he could afford to pay out of same would give quite an inadequate return for an investment of capital averaging £125 or £130 per house. Our knowledge of the agricultural districts of England is such, that better classes than "labourers"—small farmers, stewards, gamekeepers, &c., &c., for instance are housed—and comfortably—less commodiously, and much less architecturally than those provided for by these designs. A very trifling modification, and consequent expenditure, would convert some of them into habitable dwellings for gentry of moderate income; take as examples the alternative designs No. 1 and 2, or even No. 5, which contains an entrance porch, a living room 13 feet by 11 feet, a kitchen 11 feet 9 inches by 9 feet, a store 10 feet by 6 feet, and three bedrooms above of 13 feet by 11 feet 6 inches, 11 feet 9 inches by 8 feet, and 10 feet by 9 feet, respectively, with fire-places in each, and a pretty Gothic elevation; such accommodation appearing somewhat extensive for the household establishment of a *mere* labourer. The elevation of plate No. 7 is peculiarly noteworthy for its artistic and effective grouping, forming a pleasing range, though the ground plans are objectionable in a sanitary regard, owing to the proximity of a dust-pit, with a privy behind it, to the kitchen door—which it faces, at a distance of three feet, and close to a window from which light is obtained to a hall and staircase. Had not the author in his preface dwelt so specially on these designs as intended for "agricultural labourers," but kept the title of his work, viz., "Country Cottages" in view, we should not have been bound to impose in some regards—save such as refer to sanitary matters—these strictures; and judging the work in its integrity, we are far from desiring that a depreciating reflection as to his taste and skill should be implied. On the contrary, we would hail with much pleasure the substantial perpetuation of the designs, and recommend the work as in various regards instructively suggestive, and about the best of its class yet produced.

Black's Guide Books (Edinburgh). Dublin: W. Robertson.

These enterprising publishers have gained a celebrity—in the matter of Guide Books especially—throughout the kingdom; and Ireland has occupied a considerable share of their attention. "The picturesque Tourist in Ireland," is a most useful and instructive pocket volume, with a general travelling map, a chart "of the lakes," plans of the principal cities, particulars relative to all objects of interest, the best hotels, &c., &c. The smaller and more local editions for Dublin, Belfast, Cork, Killarney, the Shannon, &c., we can also pronounce by experience to be acquisitions, embracing much information, and neatly produced.

The Labouring Classes.—Owing to the extreme wetness of the present season, a considerable amount of distress has at times prevailed among the labouring class. Whenever the weather has permitted, the demand for labourers has been brisk, and wages high. Men have asked and obtained from 1s. 6d. to 2s. per diem: and women from 8d. to 1s. A number of applications for relief have been made during the last week at Garbally, and in every instance, whether the applicant was male or female, employment was at once offered; and this Lord Clancarty considers the best means of giving relief. The continuance of moist weather is, we understand, still severely felt by the poor.—*Western Star.*

Sleeping in Damp Rooms.—Rooms where the plastering was never well dried, either from the want of time or from being filled with frost before it had chance to dry, rooms in basements or on the north side of a house shaded by trees or other buildings, are very unwholesome for sleeping apartments. And what makes the exposure greater, and the results more serious, a cold is taken when the body is in an active state, and it is very difficult, if not impossible, to throw off such colds. Quite a number of cases of severe sickness have occurred in the experience of the writer from such exposures, and in two or three instances death has followed. No one thing is so conducive to health as large, airy, and well-lighted rooms for sleeping. This is very important where there are small children or feeble constitutions.

Rights of Inventors in America.—A number of hardware dealers were visited by a gentleman in quest of screws of a certain description, of English manufacture. In many of the houses he bought parcels of the English-made screws, paid for them, and, in the presence of the salesmen or members of the firms, tied them with red tape, and sealed the receipted bills thereto, and ordered them to be sent to the office of "Chas. M. Keller, Counsellor in patent cases," Nassau-steeet. Such a transaction excited inquiry, the result of which is as follows:—The gimlet-pointed screw is an American invention, and was patented in the United States and in England; the English patent having been disposed of to manufacturers there, whose goods are imported into this country and sold by our merchants, thus invading the rights of the owners of the American patent. It appears every package sold renders the merchant making the sale liable to the owners of the American patent, as in the great india-rubber case of Day and others, in which the Supreme Court of the United States decided in every case of violation in favour of the American patent. Present appearances indicate that an exciting suit is on the *tapis*, which is likely to involve quite a number of our largest hardware houses, who have sold screws to the gentleman.

FINAL NOTICE.—Patients residing in the Country desirous of consulting me relative to having ARTIFICIAL TEETH adapted should, in order to avoid being detained unnecessarily in town, apprise me at least one week previous to their intended arrival. Also, please copy my address, as I purpose (having now obtained sufficient connection) to discontinue advertising from this date.

75, DAME-STREET, DUBLIN.

JOHN O'DUFFY, formerly Head Assistant for six years to the Surgeon Dentist of St. Vincent's Hospital, Stephen's-green.

TO CORRESPONDENTS.

W. S., London (will write or see). W. F., Liverpool (shall be attended to). T. L., Nottingham (thanks; explained). J. R, Sheffield (early this month; absent when received). R. E., Cork (thanks for favours). T. M. (too late; in any case, quite too lengthy). J. B. R., Derby (as requested). W. W., Banbury (with pleasure). T, F., Scoles Fold (received, and obliged).

NOTICE.

Post-office Orders and Remittances should be made payable to Mr. Peter Roe, 42, Mabbot-street, Dublin.

☞ *NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the* Dublin Builder." *All other Communications should be addressed to the "Proprietor and Editor,"* 17, Lower Gardiner Street.

The Dublin Builder.

Vol. II.—No. 20.

ENGLISH FARMERIES AND COTTAGES.

It is a pleasant thing to view the many architectural beauties dotting an agricultural district, when such beauties can be insured free from the peculiarities unprepossessing, sometimes disfiguring them. It may be, to a certain class of poetical *antiquarians*, delightful to contemplate a thatched cottage and a stray barn after sunset on a summer evening, or to blend the Gainsborough and Stanfield school, with the leaky, cold, and uncomfortable; but we may refer to the farmer or husbandman without fear of contradiction, whether his "secluded cot" is not better with a good tiled or slated roof, his homestead and his premises well arranged so as to save somewhat of his hard-earned, frugally spent capital, than dwelling most practically (?) in an old and flimsy tenement beneath a by no means genial climate. We wish we could see the whole of Ireland dotted by the comfortable and pretty habitations fast covering the agricultural south of England, which bad landlordism and other causes have contributed to prevent her as yet accomplishing, but a few years will show that her inhabitants are not insensible to her productive soil, and that they can provide for her husbandmen, who, when properly encouraged,—are not slow to perceive it, and repay such encouragement with a sincerity and earnestness, not possessed by any other nation in the world, perhaps, to an equal degree. Having passed through the troubles of famine, and political misrule, she has but to put forth her strength, and proved that her Australian and Canadian children are "chips of the old block," and the "old block" itself remains as sound as ever.

Passing through the southern and western districts of England, we are much struck with the symmetry and regularity of arrangement of many of their farm premises; we must give high farming the credit of the impetus first given. The necessity in such a system of buildings suitable for the machinery, &c., gave rise to new ones, and this being, what we may call, the revolutionary architectural Æra of 1859-60, ideas were called in to aid in producing economy and elegance, startling the cobwebs from the corners, and rousing Mr. Clodhopper from the lethargy of—we may almost say—ages! It seemed till then, to be the exclusive privilege of the farmer to pave his floors with boulders, sleep in a drafty room, and store his money away in the bed-sacking (if he had any), and as usual in such cases—grumble enough for a whole parish. But affairs have greatly altered—metropolitan bricklayers, carpenters, and masons let loose through the country, have ripped off the weather-boarding, the thatch, and bad work, and with the aid of that ever active member of society, *the architect*, raised charming little villas, well drained, well ventilated, and in all respects filled to comfort and charm, whilst their uses are manifold and various. The gothic seems most in vogue, as being that which prevails in our public edifices, likewise private villas. But we much question the desirability of such a style for the purpose. It looks well, and combines well with our climate, and geographical peculiarities, but we doubt whether it affords the same amount of convenience as the modern English style, which we may call Italian, had we not made it our own long ago. How can it be done so cheaply, except by sacrificing strength, and quality of material; leaving the extra labor entailed upon the architect out of the question, as his commission of 5 per cent. covers all this? we must look at the quantity of material sacrificed for the sake of effect externally, and the extra time consumed by unskilled hands in this style, which admits of so many varieties in disposition of design, and therefore every time is nearly new to the workman.

In small buildings of this character, the difference may not be felt, but in those for farms running from 150 to 400 acres, it must be so. Again a quantity of room is sacrificed in a gothic farmery, which may be saved in one of Anglo-Italian construction, where every particle of area covered is actually working area, and a number of angles does not interfere with an easy and ready access to all parts of the building. We do not say that there are not modifications of this, and that a gothic elevation may be arranged to an Anglo-Italian plan, but such an arrangement is difficult and uncommon, and does not harmonise when done; and however trivial a little sacrifice of harmony may appear to a country squire or the farmer, the architect cannot offend his own eye and taste by toadyism always, even to a wealthy and influential client. The artist, the author, and the sculptor have free scope for treatment of their respective themes, the architect is crippled and thwarted, and really becomes but the mere victim of £ s. d., but he must be guided to a certain extent by the experience of those who instinctively, we may say, are acquainted with the requirements of the premises, but as regards style, and site, he must be led only by his superior judgment. However, returning from this digression we must admit that to build farmeries properly requires almost an exclusive apprenticeship; to economise space, working expenses, &c., requires an acquaintance with farming generally, but to build handsomely, and substantially, and to lay out the money for that purpose to the best advantage is known only to the designer and estimator.

In the agricultural districts of Essex and Kent, where staunchions are required, iron is generally used instead of timber, and this on stone footing. Concrete is largely used, and great care taken to prevent any sinking in marshy situations, or damp arising. Tiled roofs are rapidly giving place to slated ones, but the sooner the variegated system at present in vogue for brick elevations is dispensed with, the better for the appearance of such elevations in ten or twenty years to come. Effect derivable from colours, in lieu of projection, will prove another failure and complete deception. In the homesteads and yards oak is much used, where it can be had, and altogether a better description of workmanship prevails; where oak cannot be had, elm is substituted. The old stone dwarf columns for hay and corn ricks have given place to iron ones. Weather-boarded and thatched barns are replaced by good brickwork and slates. Exceptions to good material occur where proprietors for the sake of a false economy use up the old with the new, which is no gain, for the old is soon rotten after complete exposure to the air, and being shaken in removal, this especially in cases where old timber is re-used. In gothic structures the eave-boarding is certainly ornamental, but very liable to be warped and cracked by exposure to heat and rain alternately. But in spite of these trifling objections we must admire the change that has effected so much for the agricultural districts, and in return, as it were, for the momentary distress caused by the introduction of free trade, those benefiting by the same—viz., the city artizans—by their agitation, have succeeded in obtaining healthy and convenient lodging houses, which has again extended an influence to the agricultural labouring classes in the shape of comfortable and wholesome cottage dwellings. There is a wide difference between the wealthy farmer, and the poor labourer, but the principle of health and comfort exists alike for both, and how much do they influence the morality of the husband and father! We hope the day is not far distant, we repeat, when the whole of the agricultural part of Ireland will be dotted over with pleasant-looking well-to-do families in good and good looking farmeries and cottages.

LECTURES ON GEOLOGY.

Doctor Melville, our Professor of Natural History in the Queen's University, has, during the month of July, been delivering the third annual portion of the course of lectures founded by the late Doctor Swiney, and though more immediately associated by the testator with the British Museum, they have been, with great propriety and convenience, delivered at the Geological Museum, in Jermyn-street. The two first series of twelve lectures each were devoted to the consideration of stratified rocks, and that just terminated has been chiefly confined to the phenomena and results of volcanic agency.

Doctor Melville is so thoroughly master of the subject, has so perfect a memory, and such ready flow of language, that he discourses throughout the hour appropriated to each lecture without any apparent reference to memoranda, and yet, to borrow a geological idiom, is never *at fault*, but keeps the attention of his auditory supplied by most interesting verbal details, illustrated by an extensive series of maps, sections, diagrams, views of the general scenery and surface of volcanic districts; together with numerous tabulated statements, all of great value in relation to the subject and in promoting its popular exposition.

In the course of these lectures the Professor frequently dwelt on the features of Irish geology, noting the formations, peculiarities, and products. in which the country is so rich. We feel, indeed, that as our native stores in this respect are developed and made known, the exportation of many substances of beauty and usefulness will increase, and our general prosperity be promoted.

THE PURGATORY OF THE BATH.

Long and persevering homilies from the medical profession on the virtues of water on the functions of the skin, have had the happy effect of establishing the cold bath amongst our permanent English institutions, and spreading widely the habit of employing frequent and tonic ablutions with cold water, which may be described as amongst the chief fortifiers of the British constitution, and the wonder, but not the envy, of continental nations. The cold bath is certainly better understood in England than anywhere else; but it may reasonably be doubted whether the warm bath has been studied with equal success. Our notion of warm baths includes merely a great deal of hot water, or hot vapour, and a certain proportion of soap, or medicinal tincture, according to the purposes of the bath. This was not the hot bath of the ancients; this is not the hot bath of the orientals. They employed a far more ingenious and a far more effective combination of hot air, hot vapour, hot water, and skilful frictions. Such were the baths which Hippocrates, Galen, and Celsus prescribed: such were the baths of which Homer sings the praises in the "Odyssey," and which Herodotus says that even the Scythians used in the Trojan War. These were the baths of which Justin records that the Romans taught the art to the Spaniards as early as the Second Punic War; and of which Julius Cæsar brought the secret even to these islands. Of the stately erections consecrated to the service of the bathers remains are yet widely extant—monuments of luxury and splendour. The art has long fallen into abeyance in the west, but has survived in the east. Its restoration has been amongst the consequences of the Crimean War. The luxuries of the Turkish bath were then so widely felt that the attempt to introduce it into Great Britain has met with a deserved success. The credit of this revival is greatly due to Dr. Haughton, who has energetically pressed on the construction of such baths in Ireland, where they have been in use now some time, and are effecting a revolution in bathing, which has only recently extended to London.

In these Turkish baths, soap and water are purely secondary agents; they are considered as barbarous, clumsy, and effete means of cleansing. The bather is first conducted into a room, which is practically a large oven, lighted from the top, and filled with moist air. This is very far, however, from being a vapour bath; the quantity of watery vapour is small, and does not affect transpiration of water by the skin. Of course a profuse sweating is induced, and the skin is thoroughly softened. It is a hot bath without water, or rather with the aid of very little water. From this chamber he passes to another, the calidarium, where, freely perspiring, he is rubbed with towels or goat's-hair gloves; and so great is the effect of the prior treatment that the softened cuticle rolls off in thick flakes and a new skin is found beneath of which the subject of the operation little dreamed. No one who takes a Turkish bath for the first time but must be astonished at the quantity of unnecessary cuticle which he carries about with him. Adepts tell you that "It requires great dexterity to perform this well without rubbing some places too much and others too little." Now comes a drenching with warm water and soap, which is not the most agreeable part of the bath, and may be considered partially unnecessary. Then the bather passes back to the tepidarium, where he is dried and clothed in warm towels; and after a pause, then to the frigidarium, or cool chamber, where, still clothed in warm towels, he sips coffee, smokes a narghilet, and indulges in beatific sensations which only those can know who have passed through the three purgatories of the bath. The Turkish bath is an agent of such great power in restoring the active functions of the skin, and the ordinary results of its application are so peculiarly agreeable and invigorating, that it will probably excite the attention of medical practitioners in its relations to diseases. It is a powerful agent, of which the virtues are apparent; but incautiously employed by persons liable to congestion of the head or organs of the chest, it is not free from dangers, as some unfortunate circumstances have already proved.—*Lancet.*

Public Works and Buildings.—The repairs of royal palaces cost during the year ending March, 1859, £47,238 19s. 11d., against £92,034 12s. 4d. in the preceding year. Of this outlay £18,731 19s. 8d. were for palaces in the personal occupation of the Court; £11,093 13s. 10d. for palaces partly in the occupation of the Court; and £16,413 6s. 5d. for palaces not in the occupation of the Court. Government offices and public buildings cost £118,601 13s. 11d., against £94,965 18s. 10d. in the previous year. The principal items were, works and repairs, £33,556 11s. 0d.; 22,586 17s. 9d. for rent of houses hired for public purposes, being an increase of £3,000 in two years, and the penalty we pay for neglecting to build proper public offices. The unfinished Houses of Parliament cost £87,210 10s. 9d. In this sum were included works and fittings under Sir Charles Barry, £53,528 16s. 1d., with his commission, £2,345 12s. 10d.

LAW NOTES.

Arthur Canning v. *Henry Loughran.*—This was an action for the recovery of a sum of £71 13s. 10d., for work done and materials provided, &c. The defence was that £175 was paid in full as the value of the work done and materials supplied under a special contract. The issues in substance were,—was the work done, and was £175 the value of said work, and was said sum paid, and whether the plaintiff left some of the work undone and the materials unprovided for. Several witnesses were examined as to the work done, &c.

Mr. Lyons, of Lower Gardiner-street, Engineer, the Editor of the Dublin Builder, was examined as to the value of the work.

The jury found for the plaintiff for £18 sterling, after being several hours locked up in the jury room.

Counsel for the plaintiff—Messrs. Robinson, Q C., and Morris. Counsel for the defendant—Messrs. Bourke and Buchanan.

Campbell v. *Harford.*—This was an action for goods sold and delivered. The defendant contracted as a builder with the Board of Works for the erection of a schoolhouse in Newbridge. The plaintiff is a stone-cutter, and contracted to supply the defendant with stone for the work. The defendant lodged £5 in court, and pleaded fulfilment of the contract.

The verdict was for the plaintiff. £57 2s. 1d.

Counsel for plaintiff—Messrs. Curran and Byrne. For the defendant—Mr. Ball, Q.C., and Mr. Kelly.

Browne v. *Shillington and Others.*—Action by a builder, on foot of a contract with the defendants for the erection of a Wesleyan Methodist Church in Portadown, county Armagh. £3000 had been already paid to the plaintiff, who now claimed £600 in addition. Defendants pleaded that the contract had not been complied with by the plaintiff and his late partner, and also, as a set off, the amount of certain penalties alleged to have been incurred by the plaintiff for delay, &c., in the completion of the work. There was a cross-action instituted by the defendants in this case to recover the amount of those penalties.

After the plaintiff had been partly examined, the parties agreed to refer all matters in dispute, both in this and the cross-action to the arbitration of three of the special jurors.

Counsel for plaintiff—Messrs. Joy, Q.C., Ferguson, Q.C., and Falkiner. Counsel for defendants—Messrs. Miller, Q.C., and Harrison.

William Singleton v. *Henry Green.*—Action brought by a road contractor against the contractor for the construction of the Newry and Armagh Railway, for work, labour, and materials supplied by the plaintiff for the defendant's use, and money paid for the repairs of certain roads adjoining Markethill, used and injured by the defendant's carts, waggons, &c., during the execution of the works. It was arrranged that the plaintiff should be nonsuited, with leave reserved to turn same into a verdict for him for a sum of £25, if the Court above should be of opinion that under the circumstances any contract was implied by law on the part of the defendant with the plaintiff.

Counsel for plaintiff—Messrs. Joy, Q.C., Law, Q.C., and Kaye; Attorney, Mr. Barker. Counsel for defendant—Messrs. Miller, Q.C., and Harrison; Attorney, Mr. Edward Greer.

Duggan v. *Lord Dunraven.*—Action at Limerick assizes, before Judge Hayes, by a builder against the noble lord of Adare Manor, for balance for work and labour, including about £450 for extra works, which the defendant disputed as excessive. Several professional witnesses were examined on both sides.

Dismissal of the County Surveyor for Tipperary.—At the late assizes an application was made to Judge O'Brien on the part of Mr. Deane, the County Surveyor, to have counsel heard on his behalf and against his dismissal. He (Judge O'Brien) found that the right to dismiss rested exclusively in the grand jury; but where the consequences were of so very serious a nature and affected so much the prospects for life of a professional man, it would be but common justice to allow the merits of the case to be discussed before them by counsel. If the matter rested with him he would feel bound to give the County Surveyor an opportunity of being fully heard. This was but the ordinary justice which every man in this country was entitled to expect; and it would be more satisfactory to the grand jury themselves and to the public to rest their final decision, whatever it might be, upon an investigation in which their officer could be represented by counsel. The foreman intimated that they would act upon the suggestion of his lordship.

Improvement of Farm Buildings.—Lord Talbot de Malahide has offered a challenge cup for promoting the erection of "substantial houses and offices" on farms ranging from 50 to 100 statute acres The offer is a graceful and appropriate substitute for the drainage cup of the society which the noble lord has won; and is entitled to the thanks of all who are desirous of promoting the cause of Irish agricultural improvement.

A WORD ABOUT IRISH ANTIQUITIES.

We alluded last month to the close of the Architectural Session; but the annual pause in literary contributions, meetings of learned bodies and occurrence of polished *conversazioni* simply releases the votaries and pioneers of civilization from intensified mental action, to afford a season of leisure, which cannot be more worthily occupied than in intercourse with the order, grandeur, and loveliness of nature, and in a renewed study of the monuments of human intelligence.

To those in the ranks of our profession who have the opportunity, therefore, we would most urgently commend the practice of sketching and of noting the more prominent and interesting features of some tract or district to which they can command access, whether its attractions lie in the general scenery, geological demonstrations, architectural remains, historic associations, or in any of those paths of study so invitingly open to the rambler in Ireland.

> "Afar from thee sojourning,
> Whether I sigh or smile,
> I call thee still, 'mavourneen,'
> My own green isle!
>
> Fair as the glittering waters
> Thy emerald banks that lave,
> To me thy graceful daughters,
> Thy generous sons as brave.
> Oh! there are hearts within thee
> Which know not shame nor guile,
> And such proud homage win thee,
> My own green isle!" BARTON.

We think, indeed, with the poet, that there are minds of the proper mark amongst us; but it is necessary to awaken the dormant energy of native students, to show the large field of illustration before them, and upon which the eyes of more distant artists are turned with an interest it would be well for those at home to emulate.

That our architectural antiquities have been subject to most continuous, most extensive, most wanton, and most lamentable spoliation will be painfully impressed upon the minds of all who contemplate the great edifices of this metropolis, or the relics of past ages scattered over the country at large. As to our Duns and Raths, our Cahirs and Crannoges, our Celtic Hill-forts and Lake-castles, we devote them, with their associated stone implements and other vestiges of very distant times, to the students of history and the pencil of the antiquary; but we have abundant materials of more tangible and practical character, illustrative of the arts and customs of our direct ancestral race, to which the architectural artist may well apply himself. What valuable objects for delineation and study does the wide range of ecclesiastical and secular buildings, our cathedrals, churches, monastic edifices, our castles and fortified gates afford! How much interest attaches to our round towers, and what veneration to our sculptured crosses!

It is not at all surprising that such historic and artistic treasures should even at a distance be held in the highest esteem, but it is a matter of the deepest regret that no individual or associated body has hitherto taken up the work of illustration in an adequate and systematic way.

When Mr. Godwin,* for instance, first beheld the venerable group at Monasterboice, he tells us, that he had never been more deeply impressed by any architectural scene whatever. Of the same class we may mention Clonmacnoise, in King's County; Glendalough, in Wicklow; and Foure, in Westmeath.

Mr. Blake, in describing Kilconnel Abbey, said, that among the numerous tourists and archæologists who run round the country every year, there are but few who know that the west of Ireland, the county of Galway in particular, abounds with remains of the most important character as exemplars of Ireland's only perfect style of mediæval church building, and of its peculiarity as compared with the contemporary styles in England. From among such remains he chose Kilconnell for admeasurement, in consequence of its comparatively good style of preservation, and as displaying peculiarities in mass and detail.

It has been thought, that from certain assimilation to the broad character of Southern Europe, and to the flamboyant lines of the Continent, that some Spanish or Flemish element may have been introduced, either through the employment of foreign artists, or the study of foreign models. But, while thanking Mr. Blake for the good service he performed, and which it is hardly too much to hope the Institute will at no distant day render available to the public, we by no means award the position of highest importance to the Abbey of Kilconnell.

Mr. Donaldson found much to observe at Kilmallock, which he measured, not perhaps in the same painstaking way as the foregoing, but in a manner sufficient for general reference and comparison; and there are many others that would equally repay the consideration of qualified visitors in this class of buildings alone. When called on business to this country some five years ago, the gentleman we have just named employed the intervals of special duties in the eager inspection and study of our leading memorials—the professor thus setting a laudable and valuable example to the student. A stride takes him from the winding Liffey to the Boyne—from Dublin to Drogheda—where he finds ample food for admiration in the grandeur of the railway viaduct, the stupendous elevation of its roadway, and the long perspective of its lofty piers. He looks not only at this grand work, but from it, tracing on the one hand the richly wooded banks of the river as it approaches the sea, and on the other allowing the eye to wander over a rich expanse of inland scenery. In a town of such antiquity there are many items of mediæval origin, of which the bold majestic mass of St. Laurence's Gate, and the ecclesiastical ruin of Saunders' Gate, with its noble arch and certain peculiarities, formed the chief objects of attention. Of the latter he says, a great knowledge of constructive skill is evinced in the present position of this tower, which stands firm on the dilapidated piers, without any buttresses at the angles or from the masses beneath to contribute to its stability. It is a striking fragment of bye-gone times, and speaks of a noble church that once covered the area, perhaps with monastic buildings attached, and the residence of a religious fraternity. There are, he adds, several other remains in Drogheda mixed up with commercial warehouses which would doubtless yield much fruit to careful investigation.

We again notice our traveller at Belfast—the Liverpool of Ireland—the cheerful, busy appearance of which, and its wide, clean, and well-paved streets, could not fail to attract attention. He speaks commendingly of the roads in the neighbourhood, but deplores the absence of monuments of art; in fact, in the North of Ireland, where Scotland has sent her sons as settlers, so that the descendants outnumber the original inhabitants, the Presbyterian and utilistic element has produced nothing of a monumental or architectural class. Among men, simple, unpretending, thrifty, and devoted to utilitarian objects, the art element has found no response in this part of Ireland. Even in Londonderry itself, says our visitor, I did not find a single object worthy my pencil; and it was not till we got to Enniskillen that Irish antiquity and mediæval art began to indicate themselves. The object of this northern excursion, however, being the contemplation of the basaltic wonders of the Giants' Causeway, which more than compensate for any monuments of man's hand, we take leave of him in the admiration of those majestic columnar groupings and rocky precipices, which, he says, "made us feel that we stood in the centre of one of the most glorious temples of the Almighty's own creation."

---

* The Editor of our London contemporary, *The Builder*.

We must close this paper with a renewed invocation to our native students, begging them to go forth and reap the rich harvest which lies ready for the sickle; but, although much good may thus be done, we feel that a society, having for its objects the conservation and representation of Irish antiquities, would be the most effectual agency for its accomplishment. And we are sure that it would deserve a grateful recognition, not merely in this country, but throughout the British empire, and among the enlightened circles of Europe.

TOPOGRAPHICAL ILLUSTRATIONS OF THE SOUTHERN AND WESTERN SUBURBS OF KILKENNY.[*]

BY MR. JOHN HOGAN.

THE western side of the city of Kilkenny is situate along the eastern slope of a ridge which projects from the south, and is bounded on the east and north by the stream of the Bregach, and on the east by the river Nore. This district, denuded of its thoroughfares and its domiciles, of its piles of masonry, its mansions and its court-yards, would present to an observer on the opposite bank of the river the aspect of an elevated promontory sloping towards the north, and from unequal altitudes, declining to the banks of the streams which wash the irregular curves of its base. At its western extremity, this ridge attains its greatest elevation, and under the name of "Robert's Hill," abruptly descends to the bank of the Bregach. The environs of the ancient parish church of St. Patrick (including the entire district outside the south wall of the town) and the locality known by the *soubriquet* of "Shradh na buddagh," from the southern suburbs of Kilkenny. These localities preserve to our own times many of their original peculiarities. Their traditionary lore and primitive observances shed around them a degree of romantic interest which the stérn utilitarianism of modern times would despise or ignore. Social changes, resulting from various causes, have all but obliterated the primæval features worn by those quaint neighbourhoods. Each locality is rapidly changing its character; every year tends to efface some one of its surviving vestiges. To gather up a few of the time-honoured traditions, and to preserve from total oblivion the still recoverable traces of the early topography of Kilkenny, are the end and aim of this humble essay.

The town walls were erected by Robert Talbot, "a worthie gentleman," about the year 1400, portions of them are still standing, and the entire was nearly perfect a hundred years ago, at the period of Rocque's survey. This fortification consisted of three faces, which formed the northern, southern, and western boundaries of the "Hightown," and, with the river as eastern line, enclosed an oblong area, about 2600 feet from north to south, by 1000 from east to west. The south wall extended from near the south tower of the castle to the tower still standing in the National Model School grounds. The west wall formed nearly a right angle with the former, and ran in a northern line from this tower to near the bank of the Bregach River, where it turned to the east, formed a re-entrant angle, and, having reached the Bregach, thence followed the course of the stream till it terminated in "Evans' Turret," at the junction of the Bregach with the Nore. The north wall was furnished with two gates, viz., the "Gray Frerren Gate," and the "Hightown Gate." The south wall had two gates, "Castle Gate," and "St. Patrick's Gate," and the western wall was provided with three gates, namely, "Walkin's Gate," "St. James's Gate," and the "Black Frerren Gate." We will now ramble along the site of this old rampart: we shall stop at each of the principal parts, and enqnire whence led the ancient road which must have existed at the time of the erection of the gate; and as one of the most interesting localities in the suburbs, "Walkin's Gate," is now being denuded of the last traces of its primeval simplicity, so that probably in a very few years the name of even the locality will be erased from our suburban geography, and superseded by a more modern title, namely, "The Fair Green," we will, in consequence, commence our inquiry with—

Walkin's Gate.—This gate stood over the street of the same name, about the site of the present Poor Relief Office. Part of the foundation may still be seen at the opposite side of the street, at the entrance to a starch-yard. In 1628, David Rothe occupied the rooms over this gate, for which he paid the Corporation the annual rent of 8d. The gate was still standing in the year 1757, and was probably taken down to afford a more commodious approach of the Cork road into the city, about the year 1788, as the lease of the houses built on its south side, and running thence into the Sconce, bears this date, and is signed "William Davis, of Kilkenny, Gentleman."

Sixty years ago, the site of the gate at the south side was occupied by a small cottage, in which John Ayrés, one of the old Protestant *Freemen* of the town, resided. This house was subsequently taken down by the late Sir John Blunden, Bart., and the large dwelling erected now used as the Relief Office. Down to the year 1775 no house bad been built on the north side of the street, from this gate to the corner of Flood-street. A dead wall separated the road or street from the Nursery Garden, the principal entrance into which was then close by Walkin's Gate opposite the Poor Relief Office. The open space further west, since known as "Walkin's Lough," was then called "Walkin's Green." The range of cabins now partially concealed behind the grave-yard was then recognised as the "Closh," and here terminated our western suburbs one hundred years ago.

St Rioch's Churchyard.—St. Rioch's, or as it is vulgarly called, St. Rock's Churchyard, is situated at the southmost angle of Walkin's Green. A range of cabins formerly separated it from the road, and were only removed within the last forty years. In front of each of these houses a cesspool was sunk for the manufacture of manure, and I have been informed by those who saw them, that from the ends and sides of these pools, human skeletons projected out, proving that at one period the churchyard extended under the line of the present road, and, as we shall now see, it also extended down under the lough towards the centre of the Green. The tradition respecting the origin of St. Rioch's, preserved in the folk-lore of the last generation in this neighbourhood, is not without interest in our present enquiry. According to it, the bed of the lough was originally an isolated valley surrounded by woods; a spring well rippled from one of its slopes, and meandered as a rivulet at its bottom. Within the shelter of this secluded vale St. Rioch built his cell, wherein he lived for a time in solitude and prayer; he was subsequently joined by a numerous body of disciples whom the fame of his sanctity attracted to his retirement; here he died and was buried, and over his grave his followers erected a church, and dedicated it to his memory. Subsequent events converted the locality into a ruin; the channel through which the water escaped became choked up, and henceforth the beautiful valley of St. Rioch served only as a basin or pond to contain the waters from the surrounding elevations.

Whatever importance or value may be attached to this tale, it is quite certain that a "holy well" formerly existed here, and it was so generally believed by the old inhabitants sixty years ago. In the summer season, when the waters had evaporated, the custom bad long prevailed amongst the people of the locality to evacuate the deposits of the lough, and remove them for manure. About the year 1812, one Timothy Kelly, by trade a breeches-maker, but at the time of this narrative a retailer of punch and porter in the house in High-street lately taken down to erect the new grocery establishment of Mr. John Coyne, determined to carry on this operation on a monster scale. On a July morning he employed forty labourers to extract the mud from the bed of the basin; they ranged themselves in a line north from the grave-yard, and speedily opened a ravine in the accumulated *debris* carried down by the streams for probably some hundreds of years. In the course of this operation, a man named Michael Murphy, a native of this district, came on a range of stones rudely placed so as to form so many steps, about midway between the grave-yard and the centre of the green, or somewhere very close to the present Gaol-road, when he exclaimed in a tone of triumph—"*I have the well.*" He continued to remove the slimy material, and found the stones to lead to an enclosure of irregularly shaped stones, apparently placed by design; further investigations were here intercepted by the lord of the soil, Mr. Mulhallen (father of Edward Mulhallen, Esq., of Seville Lodge), who prohibited the removal of the manure by Kelly, but permitted the excavators to carry it off for their own use. I have this narrative from an eye-witness who is still living, and was standing in the grave-yard as a spectator; he heard Murphy cry out he had found the well, and he was able to recognise the stone steps at the bottom of the pit; they were not so deep as the height of a man under the level road. Much interest, but no surprise, was evinced on the occasion, as then and previously no doubt was entertained that "St. Rock's Well" was covered over by the waters of the lough. The next fall of rain restored the place to its usual appearance, and the whole transaction was soon out of mind. At that period the grave-yard was not enclosed by walls; it was inundated by water in the winter, and a desecrated common in the summer; it was, nevertheless, a place of annual pilgrimage, which continued down to our own times.

---

[*] Read before Kilkenny Archæological Society, and published in Transactions.

Dr. Petrie assures us that the primitive ecclesiastical establishments in Ireland were founded by the saints whose names they still respectively retain. Hence the relationship claimed for Rioch with Patrick and Mel, taken in connexion with the interesting topographical coincidence just noticed, reflects a new ray of light on our primitive ecclesiology, and exhibits the National Apostle and his two nephews founding here three missionary stations, which with a fourth subsequently opened by St. Kenny, ultimately grew up into so many parochial establishments, modified in name and locality to suit the altered circumstances of the times, but still retaining in the sites of the primitive churches the names of the respective founders, and the evidence that from the beginning the ecclesiastical districts or parishes of what we now call Kilkenny were numerically the same as at the present day.

It may now be difficult, if not impossible, to determine with certainty the precise period of the partition of St. Rioch's parish, or the suppression of his church, but the probable era may be arrived at from collateral and ascertained circumstances. There can be little doubt that the present ecclesiastical divisions of Kilkenny were constructed subsequent to the establishment of the cathedral here, and consequent on the foundation of St. Mary's Church and parish in the "Hightown." The Bishops of Ossory, after the Conquest, being of English extraction, naturally fostered the growth of the English colony here. Ware, in the "Life of Hugh Rufus," goes so far as to say that that prelate granted a portion of Kilkenny to William Earl Marshal; and Stanihurst records "that 'the High-town' was builded by the English after the Conquest, and had a parcel of the 'Irishtown' thereto united by the Bishop his grant made unto the founders thereof upon their earnest request." From this liberality in temporals, we may form an idea of the Bishop's munificence in spirituals; and whilst the Earl at one end of the settlement was investing his ville with political franchises and civic exemptions, the Bishop, from the opposite extremity, was endowing it with ecclesiastical immunities and parochial dignities; and hence the establishment of St. Mary's Church and parish, from which we may date the first encroachment on the ancient territory of St. Rioch.

Though it is not recorded in the "Charter," there can be little doubt that the Earl retained for his own new church beyond the bridge that portion of the parish of St. John which still lies at the south-west side of the River Nore, which includes the Castle grounds and part of the "Duke's Meadows," and which must have previously formed part of St. Patrick's parish. The annexation of this important tract to St. John's, and of the townland now known as "Archer's-street Lot," to St. Canice's, so encroached on the ancient parish of St. Patrick, that it was necessary to indemnify the representative of the "National Apostle," and accordingly the western and largest portion of St. Rioch is annexed to his parish as an equivalent. If these views be well founded, it will follow that the abolition of St. Rioch's parish was accomplished during the episcopacy of Hugh Rufus, "the first English Bishop of Ossory."

When St. Mary's Church passed out of the hands of the Roman Catholics, they soon after erected a chapel outside of the town wall. To this modern fane they carried the discipline and traditional observance of the older church, and amongst them I can trace a special honour for St. Rioch. This was manifested by a full-sized oil painting of this saint, which was preserved in "James's-street Chapel" (as it is named in Rocque's map) down to the year 1804; those who remember it, and are still living, thus describe it:—"The saint was represented seated on a rock, in the midst of a forest, clothed in a loose scarlet robe, with a dog fawning at and apparently engaged in licking the sores and bruises on his feet." Of the original history of this picture I can discover nothing. Whether, with other things that have come down to our times, it may have been transferred here from St. Mary's Church, is now impossible to ascertain. From time immemorial it was suspended at the "Epistle side" of the altar, until, in Bishop Lanigan's time, it was superseded by another painting of the same saint of more artistic pretentions. When the altar had been erected which still stands in the old chapel, the Bishop wrote to a gentleman. a friend of his, then in Portugal, to order three pictures to be painted for its decoration. These were the "Crucifixion;" the "Assumption of the Virgin," to whom the church was dedicated; and a full-length portrait of St. Rioch, the patron of the ancient parish: so that down to that period no doubt can be entertained that the privileges claimed for St. Rioch in this paper were then partially recognised. This painting still exists, and represents the saint in the garb of a pilgrim, with a flowing scarlet tunic over the habit of a religieuse, to which is attached the scallop shell, and a girdle round his waist. He stands erect in a forest; his left foot rests on a rock; he holds in his left hand a pilgrim's staff, from a hook near the top of which a travelling wallet is suspended, and to which he appears emphatically to point attention with the fourth finger of his right hand. The great peculiarity of the painting is the Irishism of the countenance, the expression of which is homely and familiar. The three pictures bear each the following inscription:—

"Eques Foschini, Ulissiponensis, Inv. et Pinxit, A.D. 1807."

The Langtons, Comerfords, Maddens, Shees, and many of the other families of Kilkenny, were the principal benefactors of the old chapel; its clergy were also natives af Kilkenny, and, in consequence, the ecclesiastical traditions of the town were more directly transmitted and more faithfully preserved then than since. If during this period the clients of Rioch assembled annually to hold his festival day on the site of his old church; if during the same period a special spot was set apart for his picture in the chapel of the "Hightown;" and if under improved circumstances, and by special design, a painting more worthy of the respect entertained for him be ordered from the Continent to fill the niche reserved for it in the new chapel, it is not evident that this veneration is but the vestige of a more ancient and extensive practice, and we may not safely infer that the Bishop who abolished his parish, and suppressed his church (to use the sarcasm of Ledwich), "to appease the tutelar saint, and to atone for the sacrilege, founded an altar or chapel" in Saint Mary's Church, "and dedicated it to him," where his memory was perpetuated and honoured, whence both were subsequently transferred to St. Mary's Chapel, where, unfortunately, they now no longer exist?*

IRISH TRAMWAYS.

THE Marquis of Clanricarde moved in the house of Lords on 19th ult., the second reading of this bill, which he said had received the support of men of all parties in Ireland. Last year a measure on the same subject passed the Lower House without opposition, and stood for a second reading in their lordships' house on the 14th of April. Parliament, however, having been prorogued a few days afterwards, the bill necessarily dropped. It had been objected to the bill that these tramways would be so good and so cheap that they would compete with the established railway; but there was a clause in the bill which amply provided against any such consequence. He was informed upon good authority that in America 34,000,000 persons had been carried with only twelve cases of bodily injury, and he defied comparison in safety between tramways and any other kind of conveyance.

The Earl of Lucan entertained the strongest possible objection to the bill, and denounced it as a cheat, a railway bill in disguise. The "horse" tramway might be turned into the "locomotive."

After a brief passage at arms between the "noble Marquis" and "the noble Earl," Lord Lifford said there was no fear that inferior lines of tramway would run across the country, because as much care was taken to select good lines as in the case of railways. The lines must be approved by the Irish Boards of Works, and afterwards by the Lord Lieutenant, and then ultimately they must come before Parliament for approval, the only difference being that the Lord Lieutenant would take charge of each bill, and that the promoters would be saved the expense of a private bill. He trusted that their lordships would read the bill a second time.

The Earl of Mayo came down with the intention of opposing this bill, believing that there was an ultimate design of turning these tramways into railways. After hearing the speeches of the noble lords who advocated the bill, he had, however, altered his opinion, and should support the second reading.

The Marquis of Clanricarde implored the house not to throw out the bill, it being a measure of a most benificial and practical character.

The motion for the second reading was then agreed to.

---

* Since this paper was written, the picture of St. Rioch has been purchased by the Rev. M. Birch, P.P., for the parish chapel of Muckalee, so that his memory has perished where it was designed to be preserved.

RAILWAY COMPANIES COURTESIES TO EDITORS.

We desire to make special mention of a circumstance connected with our Editorial mission, which it would be ungracious to withhold, as the least return that the recipient of a favour can make therefor is to *acknowledge* it. Our allusion refers to the courteous readiness with which the Great Southern and Western, and Midland Great Western Railway Companies of Ireland, respectively, have placed their lines at our service when the interests of our journal rendered "a trip" desirable. To the former company, therefore, our readers are indebted for the particulars of the progress of "Cork," personally collected—and the accompanying illustration as given in our July No.—and to the latter for references which appear in current No. to those towns in the province of Connaught. The favour thus accorded is by no means slightly gratifying to us; it makes us feel that our mission, which is exclusively of a scientific, artistic, and industrial character, is appreciated, and it somewhat flatters our vanity at having been so fortunate as to pursue it satisfactorily so far. Independent of the compliment to ourselves personally, the public—at least that section of it to whom the Dublin Builder finds its way, and which we are happy to state is with each succeediug month extending considerably, both within and without the pale of the profession—are, to a certain extent, Dr. to the donors; and with that view, therefore, we adopt this mode of public acknowledgment.

THE VACANT SURVEYORSHIP.

We learn that the offices of County Surveyor, rendered vacant at Londonderry by the death of Mr. S. Gordon, and for the South Riding of Tipperary by the dismissal of Mr. Deane, are about being filled by the appointment of Mr. Worrall, C.E., to the former, and the nomination of Mr. Bower, C.E., to the latter. As both gentlemen are favourably known to the profession and the public, we have no doubt but that the selection will give general satisfaction. In the latter case it is probable that the appointment may not be officially made until the pending appeal of Mr. Deane for wrongful dismissal shall have been heard, and the opinion of the public should therefore be suspended.

SANDFORD CHURCH.

The works now in progress at this church consist of an addition to the western end in the Italio-gothic style, and the removal of the plaster ceiling internally, the present roof timbers being exposed to view, the under side of the rafters sheeted with deal, the roof trusses wrought and rendered ornamental by certain additions, and the whole stained and varnished. The addition is calculated to give some architectural pretension to the present very unprepossessing structure, and affords internally three porches with entrances, stairs to gallery, and an organ loft. In the front elevation is the principal entrance, a deeply recessed semicircular arch, springing from four columns with sculptured capitals, and divided within into a double doorway over which is a tympanum filled with decorative perforations. Above, the face of the building is divided into three bays by pilasters, terminating in an inclined corbel course under the cornice,the central bay is filled with a handsome rose window. The gable follows the slope of the present flat roof, and is surmounted by a deep cornice. There is a bell turret with an open belfry stage and pyramidal stone roof on the southern side. Certain portions of the work are intended to be commemorative of the late Archdeacon Irwin, and to bear suitable inscriptions. Messrs. Lanyon, Lynn & Lanyon, of 64, Upper Sackville-street, are the architects; Mr. Butler, contractor. The first stone of the addition was laid on the 25th ult., by the Archdeacon of Kildare.

Under the same architects, there is in course of erection near Naas, in the county Kildare, an extensive mansion for Richard Moore, Esq. Style, a modern adaptation of Elizabethan. Messrs. Cockburn & Sons are the contractors. Mr. Drew is acting as clerk of works.

CASTLEBAR.

A retrograde movement is painfully palpable in this, the Metropolis of Mayo, and the word progress seems to be absent from the vocabulary of every class, commercial and otherwise, throughout. This fact is greatly attributable to the depopulation of the rural district by famine, consequent fever and emigration. The town numbers some 4,000 inhabitants, not one-third of whom would seem to be even in moderately comfortable circumstances; filth and misery are everywhere prevalent, and the neglect of the authorities in sanitary respects is superlatively reprehensible. Yet withal the elementary faculties tending to comfort and prosperity, are, to our mind, present, however blind the inhabitants may be to the fact. Westport bay is within 7 miles, Ballina and Swinford respectively distant some 16 and 10 Irish miles; assizes are held twice a-year, at which large numbers congregate; and with a noble country in the immediate vicinity of the town itself, the centre of an important agricultural district, and other advantages of which more prosperous towns cannot boast, the backward condition of Castlebar is unpardonable, and suggests the supposition that the fault must lie in the indolence of its inhabitants. At the termination of the main street—which is much narrower than in other towns, and with shops and dwellings of paltry character at either side—is a large green with spreading trees comprising about one acre, and affording a spacious promenade for the inhabitants. At one side of this square is the Court House, originally designed by the late Mr. Papworth, and having a hexastyle Grecian Doric portico of iron, and plain wings one story high with compo'd front; but recently considerable additions and alterations have been made thereto, the wings elevated to two storeys, and finished with pediments of chiselled limestone, under the directions of Mr. Wilkinson, architect; Mr. Cooley, a local builder, being the contractor. The internal arrangements comprise a central hall with a long flight of stairs leading to upper storey. the Record Court being at one side, and the Crown Court at the other, with judges', barristers' apartments, &c. Referring to the new works, Judge Christian at last assizes remarked "that however the Court House was improved in other respects, it certainly was not in point of hearing." The other public buildings are the County Infirmary, an antiquated structure in the Green, a magnificent barracks for 1,000 men, but untenanted, and the grass growing in the square—a significant sign of the peace of the country—the Protestant Church with square embattled tower, erected by the Board of First Fruits, and with a monument externally to the late Major-General O'Malley; the workhouse, a very extensive block of buildings; the new county Gaol, in the castellated style, designed by Mr. Darley, and erected in 1834 at a cost of £23,000; a large poorhouse, and a repetition of the old barn model for a Roman Catholic Chapel. The Earl of Lucan has a farm close to the town, with an extensive farmstead, and sawing machinery; but the dwelling-house has closed windows—the type of absenteeism—and the general aspect of "the Lawn" is by no means of *a model* character. In Castlebar the builder's occupation is completely gone, for the present, but we anticipate some reaction when the new Lunatic Asylum, for which we learn the grand jury have directed Mr. Wilkinson to prepare plans, is about being erected. This town is associated in historic memory with the expedition of the French to Ireland in 1789, and a sharp battle which resulted in the rout of the latter, took place on an elevated site in the immediate suburbs.

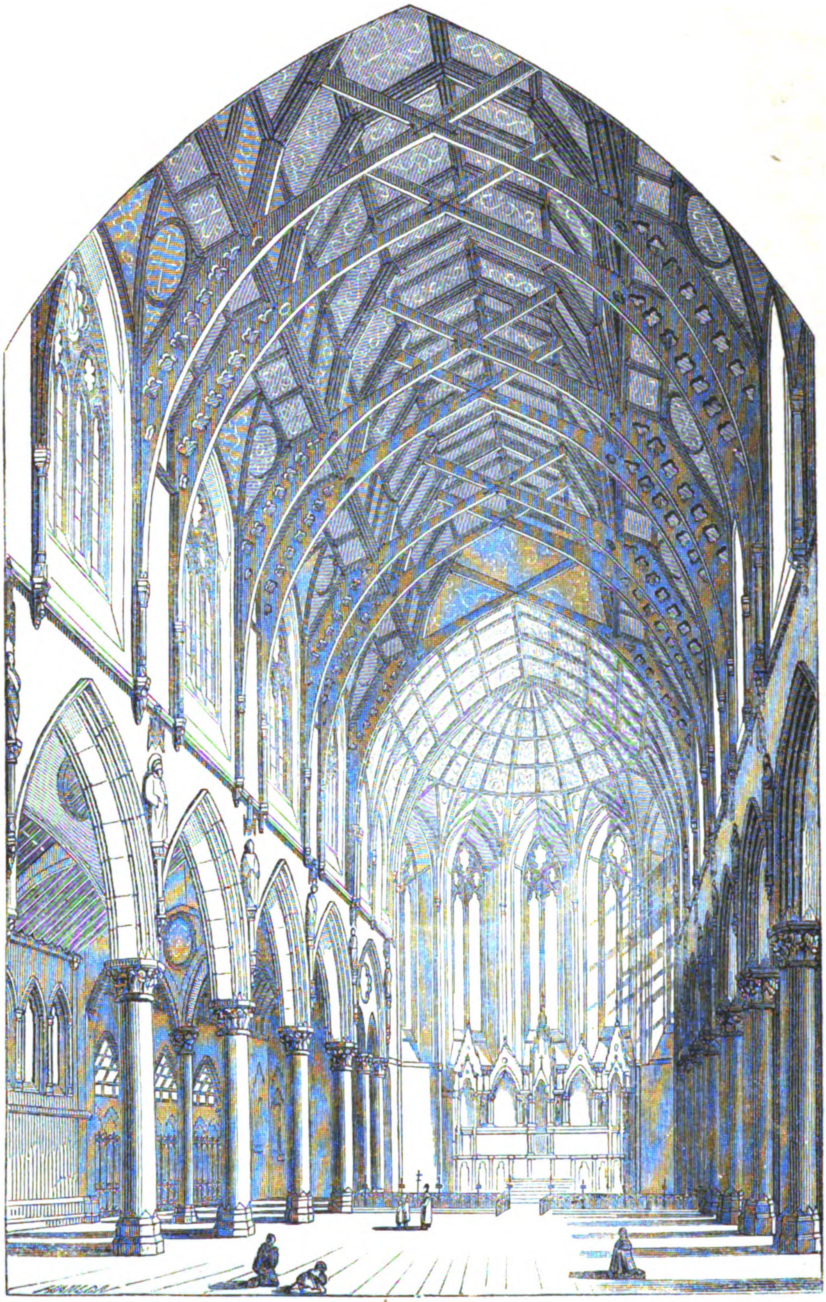
BRITISH LABOUR.

The *Architects' and Mechanics' Journal*, of the 7th ult., says, that "In England, Scotland, and Ireland labour is in a very unsettled state, and much suffering is anticipated amoug the working classes. In London a strike for the nine hours movement is contemplated among the building operatives. In Cork the masons are on a strike, and much suffering is the consequence." In some respects we will not question the accuracy of the above; but, as regards the unsettled state of labour in *this* part of the British Isles, we must remind our contemporary that, far from that being the truth, the supply is by no means commensurate with the demand for skilled able-bodied labourers; also, that the strike of the masons in Cork was but of very temporary duration, and the best feeling has been secured between master and workman.

STATUE OF SIR CHARLES BARRY.

Lord Palmerston was waited upon the other day by a deputation of the Institute of Architects for the purpose of submitting a proposal in reference to such a mark of honor to the deceased architect of the Palace of Parliament. His lordship is understood to have expressed his personal acquiescence in the erection, by the Government, of a statue of Sir Charles in the raised extension of Westminster Hall, between St. Stephen's lobby and the immediate access to the "Houses." A better site could hardly have been chosen.

THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS



INTERIOR OF NEW CHURCH OF SS. PETER AND PAUL, CORK—Messrs. Pugin and Ashlin, Architects.

NEW CHURCH OF SS. PETER AND PAUL, CORK.

A brief notice of this building with particulars collected during a recent personal visit, was given in the July No. of this journal, and we now present our readers with a view of the interior looking towards the chancel, and engraved by Mr. Hanlon from a photograph furnished to us by the architects, Messrs. Pugin & Ashlin. As already stated, the site for the church is by no means favourable to the display of its beautiful features, and must not a little interfere with the pardonable vanity of the architects, who, as a matter of course, would have preferred to have had its parts displayed to the best advantage, and not with its "light hid under a bushel," as unhappily is the result of the site chosen, let who may be to blame. Even to obviate this difficulty in a degree hereafter, an expenditure will be necessitated, which, if our information as to financial matters be correct, will prove quite impracticable; it is, therefore, a subject for regret by all concerned with the undertaking and by the citizens, that this truly handsome architectural work on which an important sum is being expended, should be so completely obscured that a stranger shall have to seek for it, and experience a difficulty in discovering what should be a prominent and conspicuous feature amongst the monuments of the city. The length of the church—which is cruciform on plan, and comprises nave, aisles, transepts, chancel, &c.,—is in the clear 145 feet by 80 feet, the nave being 35 feet in width, and the height to apex of roof 87 feet 9 inches. The construction of the roof presents some noteworthy features, and the proportions of the arcades separating nave from aisles are graceful and lofty. Five two-light windows with plate tracery heads, light the chancel, which is semi-dodecagon in form, and measures 35 feet by 17 feet 6 inches in clear. A handsome tower 27 feet 3 inches square at the base tapering to 25 feet 3 inches, and surmounted by a beautiful spire attaining an altitude of 232 ft., is to be placed at the western end. The materials employed throughout are Glanmire red stone for walling, limestone for the dressings of doors and windows, quoins, &c., and Portland for the tracery. The shafts of the arcade piers are of marble, with polished limestone bases and caps; those in the chancel are of Connemara green, and the ornamental portions of Caen stone. The cost, exclusive of tower and spire, will be about £11,000; the builder is Mr. Barry M'Mullen, and the clerk of works, Mr. Langford.

THE *DUBLIN BUILDER* AND THE WORKS AT ST. PATRICK'S CATHEDRAL.

We are taken to task by the *Evening Mail*, which somewhat erroneously entitles this journal the *Irish* Builder, for a correspondent's letter that appeared in July No. with reference to the works now in progress at St. Patrick's Cathedral, and a polite intimation of surprise is conveyed "that any Irish journal would allow itself to be the medium of so paltry and transparent a manifestation of ill-feeling." Assuredly our contemporary misconceives greatly the principles on which our journal is being conducted, if for a moment it supposes that we would willingly allow its pages to be perverted into a conveyance of either private pique or professional jealousy; and, moreover, it could not have arrived at such a sweeping conclusion if the critic for our contemperary had read our *Editorial* remarks on the same subject at page 274, June No. We are not disposed to take up the cudgels for our *incognito* correspondent in substantiating his statements as to the precise nature of the works in progress, or in justifying his suggestions; but we confess that we are unable to trace throughout his remarks that "manifestation of ill-feeling" discovered by the *Evening Mail.* To prevent misunderstanding, however, as to *our* position in this matter, we may mention, that on being apprized of Mr. Guinness' handsome gift, we desired to place the earliest and most authentic intelligence before our readers and the public, and for that purpose we wrote in an editorial capacity both to the Dean of St. Patrick's and to Mr. Guinness himself, requesting to be favoured with particulars, for publication, as to the nature of the proposed works, but *neither of those communications were answered.* Our subsequent reference *to the fact* of Mr. Guinness not having called in professional supervision for such an important work, is one which *on principle* we felt ourselves in duty called on to make, and to which we still faithfully adhere; but our contemporary will please to bear in mind that it was conveyed without reflecting on the laudable intentions of the donor, or any party concerned, and *without* "any display of professional spleen or disappointment." We would also remind the *Evening Mail* that the Dublin Builder, as a professional and class organ, is not singular in its strictures, as *The (London) Builder* of similar mission—which probably may get more credit for disinterestedness than *we* do—of the 21st ult., has the following correspondence and editorial remarks on the same matter:—

"*The Cathedral of St. Patrick, Dublin.*—Sir,—It has been frequently stated, and as often denied, that the extensive works here are being proceeded with without efficient professional superintendence, if any. Can any one throw any light on the subject? Or, if the Dean and Chapter and Mr. Guinness have been unjustly accused, can any one name the gentleman or gentlemen to whom has been entrusted the delicate task of renovating and restoring the most perfect remnant of mediæval glory in this country.—Delta."

"We have every reason to believe that there is not any architect superintending the works at St. Patrick's Cathedral, although the donation of Mr. Benjamin Lee Guinness for its restoration is £20,000; and it is understood that if that amount be insufficient, more funds will be forthcoming from the same quarter. The builder (Mr. Timothy Murphy) appears to be proceeding partly on plans made some time ago. The sooner a proper architect be appointed the better, or Mr. Guinness, instead of doing the good he desires, and gaining the credit his liberality deserves, may find himself justly reprobated or ridiculed for his share in an injurious vandalism."

Memorials to the late distinguished architects, A. Welby Pugin and Sir Charles Barry, R. A., are proposed; the former consisting of a statue, to be placed in the Palace of Westminster, and the latter a travelling fund for the education of young architects.

A new free public library is now building in Worcester, Mass. It will front 60 feet on Elm-street, and is 75 feet deep. Its exterior will be of the best pressed brick, with freestone trimmings. It is two stories high, with the exception of the south-east corner, which is one story of 21 feet in height, that it may be lighted from the roof. The front is plain, with a French roof and portico at the entrance.

THE AGRICULTURAL SHOW AT CORK.

The preparations which for a lengthened period have been making in this city to ensure a creditable display at the exhibition of agricultural produce and implements, of cattle, poultry, &c., have proved most signally successful; and the result may be pronounced as one of immense National, as well as local importance. The Corn Exchange building was dressed in its gayest attire, and a quantity of new work executed in adapting and adding to the interior for the reception both of the biped and quadruped visitors. An additional impetus was given to the well-known energetic faculties of the Southern Metropolitans in providing a fitting reception for the Lord Lieutenant, who, with his usual anxiety for industrial advancement, considerately lent the prestige of his presence—no small trifling element of success—to the occasion. Irrespective of the temporary new Cattle sheds, which we may remark *en passant*, were of appropriate construction, and tastefully decorated with many-coloured striped calicoes, a spacious and permanent supper room, 90 feet in length by 30 feet in width, was also added. We likewise noticed what the readers of the Dublin Builder must admit we have both by precept and illustration sought ardently to introduce more extensively into this country, viz., an abundant supply through drinking fountains of the *aqua pura.* Two large troughs for animals were erected in the promenades, at either sides of which were ranged the cattle, &c., stalls; and two in the implement yards, besides which we should not omit to mention a jet supplied with a liquid more fragrant than useful, viz., *Eau de Cologne*, before his Excellency's table. We must reluctantly, but in deference to *our* province, pass over in this notice many matters interesting to the general reader, and confine ourselves to such departments only as have a relation thereto. The prize cups and piece of plate are very beautiful specimens of art, two of the former being respectively entitled the "Peter Purcell," and "The Waterford," value 100 sovereigns each, and two others "The Croker," and "The Irish Farmers' Gazette," value 50 sovereigns each. The names of the general exhibitors in the implement and other apparatus department are familiar to our readers, and amongst them we notice Messrs. Garrett & Sons, of Suffolk, Smith & Ashby, of Stamford, Richmond & Chandler, Manchester, Ransomes & Sims, Ipswich, Barrett, Exall & Andrewes, Reading; Musgrave, brothers, Belfast; Perrott, Cork; Murphy, Cork; Shekleton, Dundalk; Kennan & Son, Toole & Co., William Daniel, Dublin, and numerous others.

DIOCESAN SEMINARY OF THE HOLY CROSS, CLONLIFFE.

This intended building, the erection of which will be immediately commenced, will be 260 feet in length, and five storeys in height; the basement storey will be half sunk and 14 feet in height; it will contain refectory, 71 feet by 28 feet, stores, kitchen offices, servants' rooms, corridor, bath rooms, &c.; the principal storey will be approached by a very wide flight of stone steps, and through a rustic stone portico, supported by rectangular pillars, and will contain entrance hall 23 feet by 15, reception rooms 23 feet by 15, study hall 41 feet by 30, library 23 feet by 30, chapel 23 feet by 40, corridor 12 feet wide, and a suite of four classrooms, varying in size from 28 feet by 30, to 10 feet by 23 feet. The upper storeys will have central corridors, with suites of sleeping apartments—70 in number—on each side, together with eight professors' rooms, and four sitting rooms each 17 feet by 30 feet. The exterior will be of a plain and massive character, cornices and string courses of granite will mark the separation of the storeys, a large central projection and deep projections on the wings will divide the façade into three portions, on the central portion only the windows will have heavy stone dressings, and with the exception of granite quoins, the entire surface will be plain. Mr. John Bourke is the architect.

Proposed Exhibition of 1861 at Dublin.—A meeting of artists, manufacturers, and others interested in the proposed Exhibition of 1861, met at the Royal Dublin Society House, on the 26th ultimo, and the preliminaries for an exhibition in 1861 were arranged.

THE CATHEDRAL OF ST. MEL, LONGFORD.

DURING a recent visit to this town, we had an opportunity of inspecting the Cathedral, now partially completed; and it is, without doubt, a noble pile of building; perhaps, indeed, the most so of any Ecclesiastical structure in progress in this country. When fully completed we have no doubt but that it will reflect high credit on the architect's (Mr. John Bourke) skill. We subjoin a few descriptive particulars.

The Cathedral of St. Mel's was originally designed by Mr. Keane, architect, but at the accession of the present bishop the works were entrusted to Mr. John Bourke, architect, who modified and altered considerably the design for the interior, and added two additional columns to complete the cella and support an organ gallery. The building is cruciform on plan (containing three great vestibules, over the central one of which will be erected the campanile) nave with apsidal termination, aisles, transepts, sacristies, libraries, confraternity rooms, &c., the extreme length including portico being 240 feet, and the breadth in clear of nave and aisles 87 feet, and across transepts 130 feet. The nave is separated from aisles, and the aisles from transepts by Ionic columns of native limestone, with arches springing directly from the capitals, and at the intersections of the arch mouldings are half length figures of demi-colossal size in various attitudes of devotion. Above all, a heavy entablature is continued, and the ceiling of nave is semi-cylindrical divided into double recessed coffers by *arcs doubleaux*, the lower portion being pierced by Dioclesian windows lighting the nave. The aisles and transepts are ceiled with deeply-recessed coffers, and have heavy dentil cornices. The erection of the campanile is about being commenced after an altered design by Mr. Bourke, and will be in three compartments, the first octagonal, deeply-recessed on four faces, and containing niches for figures of the four Evangelists, together with a pedestal for the statue of St. Mel; the second to be a couple columned temple, containing a belfry and having pediments, inverted trusses, &c.; the upper, or third, will be a drum, crowned by a dome and pierced with circular and rectangular opens, the whole surrounded by an open lantern and gilt bronze cross at a height of 166 feet from the ground. The erection of the great portico, 96 feet in length, has been delayed owing to the difficulty of transporting blocks of native limestone of sufficient size, which probably may cause the adoption of Portland stone instead, which can be brought into town by direct water carriage.

INTERNATIONAL STATISTICAL CONGRESS.

"IT is no common period," says Mr. Morris in "A House for the Suburbs," "when the highest in rank pride themselves more on their absolute usefulness than on barren titles." An observation which has been illustrated in a remarkable manner by the Congress on International Statistics assembled in London, and attended by many whose names stand high in the social and scientific ranks of Europe. The Prince Consort delivered an inaugural address, on the 16th ult., in which he with great modesty welcomed the delegates to this country, and in referring to the origin and object of the assemblage, alluded to it as one of the results of the Exhibition of 1851, as well as to the recent place assumed by statistical knowledge among the sciences; and to its importance, not only to governments as an enlightened basis of taxation, but to general commercial and individual enterprise, enabling the economist to deduce from the facts of the past the probabilities of the future. The necessity for extreme accuracy, and the most exact definition of terms employed in statistical reports was also pointed out in the "able, well-reasoned, and most useful address of His Royal Highness."

After some remarks from Lord Brougham, and an address by the Brazilian Minister, delivered in French and replied to by the Prince in that language, the Congress was declared to be open for the transaction of business, and we have no doubt that to its deliberations very important social results to this, and other countries, will be attributable.

An important auction of timber will be held on 7th inst. by Messrs. John Martin & Son, in the Custom House Dock. (For particulars see advertisement.)

The new organ built by Messrs. White, of this city, for the church of St. Paul, Arran-quay, is to be opened on this day. It is a magnificent instrument both as regards power, tone, and finish.

The adoption of the Towns Improvement Act in Tullamore has been carried by a majority of 20; the voting being, for the bill 57, against it 37.

The import of Canadian timber this season to the United Kingdom will considerably exceed that of former years. The price of labour at Quebec has reached an exorbitant pitch.

BALLINA.

THIS town possesses all the elements which, if properly applied, would constitute it one of the most important in Ireland, and it is peculiarly favoured by its proximity to the Atlantic on the one hand, and in being surrounded by a beautiful country of rare agricultural excellence on the other. The population is about 5,500 inhabitants, and has been numerically increasing steadily since the famine of 1847. Every Monday there is a market held, and a large amount of business transacted, chiefly comprising exports of corn, eggs, and butter; four fairs are likewise held during the year. The town has macadamized streets, and paved pathways; and ground in the principal streets, viz., Knox-street, a spacious thoroughfare, is subject to one guinea per foot, and in some instances a higher rent. In 1846 a considerable improvement was effected in this street by the removal of a block of barrack buildings immediately opposite the Royal Hotel, and by the substitution of a new range after plans by Sir John Benson, architect, ensuring an increased and uniform width, but during recent years there has been very little building work of a commercial character executed. The Poorhouse is the most extensive building in this town—as unhappily it is in nearly every town in Ireland—and, excepting the Roman Catholic Church to which a beautiful tower and spire about 185 feet high was built a few years since by Mr. Canning, a local builder, after designs by Mr. J. J. M'Carthy, architect, may be regarded as the only public building with any architectural pretensions. In 1798 the French landed at Kilcummin, near Killala, and marching to Ballina they took possession of it without resistance. The river Moy which runs through this town is navigable at high tides within a mile and a half of the main street, for ships of 200 tons burden, and an eminent engineer, Mr. Ball, estimated that an outlay of £80,000 would render it capable of accommodating vessels of much larger burden by means of a canal on the Mayo side having a lock constructed about a quarter of a mile distant, and a floating basin from thence to Ballina bridge. There is excellent salmon and trout fishing in this river and its tributaries, and the water power for mills and factories is unlimited, though unfortunately, like many other resources at the command of our countrymen, not taken advantage of. The rural districts are thinly populated and chiefly devoted to grazing purposes, the character of the land being pasture of the best quality. Moreover there are building materials in abundance, an excellent limestone, brick clay—though the process of manufacture is by no means good—lime, sand, gravel, &c. Timber is imported chiefly from Quebec and St. John's in sufficient quantity, but the cargoes of the vessels have to be lightened, and the logs floated up the river. There would seem to be an advantageous open for an enterprising capitalist in building materials to start a depot in this town, and establish sawing machinery now so extensively in vogue in other districts. Gas works have been comparatively recently introduced here, and erected by Messrs. Donald, Wilson & Co., of Paisley, on their own speculation, with a guarantee from the Town Commissioners of £200 per annum for the public lights, the quality of the gas being equal, at least, to that of the Metropolis, but supplied to the inhabitants at the high figure of 8s. per 1000 cubic feet, irrespective of metre rent. We hear that two new banks are to be built immediately, one by the National Banking Company and another by the Provincial, both having at present branches in the town, but unsuited in their capacity for its growing requirements. We trust that we may be enabled soon to chronicle additional exertions on the part of the Town Commissioners who, to do them justice, seem to make the best use at present of limited means in sewerage and cleansing operations.

At Crossmolina a new Roman Catholic Church is in progress of construction after plans by Mr. Canning, of Ballina, Mr. John M'Gurrin, builder. The dimensions are 115 feet by 90 feet, with transepts and chancel; style, Gothic. Differences having arisen between the architect and builder relative to constructional questions, they have been submitted to the arbitration of Mr. J. J. Lyons, of Dublin, architect, whose decision is final.

GOVERNMENT GRANTS TO SCIENTIFIC AND ARTISTIC INSTITUTIONS.—Amongst the items of grants voted for Irish establishments of this character we find included for the Geological Survey of Great Britain and Ireland £10,318; for the Royal Dublin Society, including the Botanic and Zoological Gardens, £6,000; the Museum of Irish Industry, including provincial lectures, £4,996; and the Royal Hibernian Academy, £300.

KILLYNON MANSION HOUSE.—This magnificent dwelling-house, which, with a spacious suite of offices, was erected after designs by the late Mr. Joseph Nash, architect, and 600 acres of a demesne delightfully and advantageously circumstanced, are for sale by private contract.

THE PIER AND BREAKWATER AT GALWAY.

A deputation consisting of several members of the Harbour Board, waited on the 24th ult., upon the County Grand Jury, to receive from them a renewal of their declaration to guarantee a tax of one penny in the pound for the interest on the money required in the erection of a pier and breakwater, graving docks, &c., at Galway.

The Chairman of the board said that matters connected with this project looked better, and in order to give accommodation to their increased shipping, and to passengers and traffic, they would require a pier and breakwater. It was intended by the Commissioners to procure the consent of the ratepayers at the special sessions also. The ratepayers of the county would be represented at the board by three of the grand jury, who would look after their interests.

Sir T. N. Redington moved the following resolution:—"That the Grand Jury of the County of Galway deeply deplores the rejection by the House of Lords of the provisions in the Galway Harbour Bill (1860), by which the guarantee of this county for securing the necessary funds for the improvement of the port and harbour of Galway were proposed to be legalised, and that we hereby declare our readiness to give the said guarantee of one penny in the pound on the valuation of this county, for securing the sums required for the improvement of the harbeur and port of Galway, by the formation of a pier and breakwater, and graving and other docks; and we trust that in a future session such a proposition may receive the sanction of the Legislature."

Mr. Bodkin seconded the resolution, which was passed unanimously, and the deputation withdrew.

OBITUARY.

We regret to have to announce the death of Stewart Gordon, Esq., C.E., County Surveyor for Londonderry, an appointment which he held for many years with much credit, and enjoying the esteem of a wide circle of friends and others with whom in the course of his professional avocations he came in connection.

REMOVAL OF CITY CHURCHES, LONDON.

By a Report lately made to the Home Secretary, it appears that the Rev. Charles Hume proposes to remove the churches, but to leave the cemeteries, while the inspectors incline to the removal of their contents also to fitting places of sepulture; and it is contemplated that by the removal of the churches least used, a fund would be raised sufficient to provide for the religious instruction of many thousand people with perhaps thirty new schools.

Among the characteristics of the sister capital must be classed its wonderful regenerative faculty. Not only has much of the city of Queen Anne's time been rebuilt, but the very lines of street have been greatly altered; the approaches to the new London Bridge, including the noble thoroughfare of Cannon-street, are notable examples, and Farringdon-street, which opens up the town from north to south, is another great instance of the same kind. Still the thoroughfares are choked, and new arteries of traffic are in process of formation. The fine Post-Office, erected by Sir Robert Smirke, is notoriously too small for the augmented affairs, and it may possibly be found in a few years converted into a warehouse for Manchester goods.

A century and a-half has scarcely passed since Wren left many churches in a state of pristine completion, and the consecrating prayers were breathed over each little cemetery, devoting it to what then appeared an immutable destination. But how changed are men's views, objects, and interests in the same place at the latter half of the nineteenth from those which swayed them in the beginning of the eighteenth century? It is perhaps well that it should be so—the change is of wholesome savour; for albeit churches which might have endured for ages must be demolished, and the venerated bones of London worthies must be disturbed, it is proper for us to see to the living and to admit the necessity of change.

The new portion of the city of 1710, fresh from the hands of the architect, was no doubt an attractive place, and its merchants were satisfied to pass their leisure, to pay their tribute of religious observance, and to take their long, long sleep in the place where their daily pursuits had been followed, their daily bread had been gained. They had indeed little choice—they were simply the creatures of their time, as we are of ours; there was little security beyond the precincts of the town, and comparatively little correspondence with the extramural world. The change of habit but keeps pace with the workings of science, the development of commerce, and the influence they exercise on the mental calibre.

The intervening period has been prolific in mechanical inventions, opening out many channels of labour, and thus drawing into habits of industry thousands that would otherwise have pestered society in every form of vagrancy and destitution. Education has been growing in favor with the people. Schools bearing on the wants and opportunities of every class have been established; the mode of teaching has itself become a science; friendless and deserted children of the poor are trained to habits of usefulness, and the asperities of the criminal code have been softened into measures of reform.

As safety enlarged its boundaries on the one hand, and commerce extended its demands on the other, the principal merchants withdrew to the suburbs; and this example has been so continuously and extensively followed, that the city is at this time devoted almost exclusively to business and depopulated as soon as its daily objects are completed, and the busy swarm found on 'Change at three o'clock are dispersed by six in every direction accessible by railway, boat, or road. Verifying the remark, that "The pursuits of the city and vocations of the town are about to be exercised by a tidal race, whose daily ebb and flow will be as regular and decided as those of Father Thames himself. The doom of intramural sepulture has become the signal for extramural life, and the very altars, from which the holy incense of praise and prayer have ceased to rise, are about to follow in this remarkable exodus."

LIVERPOOL DOCKS.

STANLEY AND WAPPING WAREHOUSES.

A century ago, across the Irish Channel, Liverpool, a small and unimportant town, with few pretensions to be called a seaport, began to interest commercial men, and since the period of the American Declaration of Independence has rapidly arisen to size and affluence. A constant stream of trade continually running through between Manchester and the Western and Midland districts with the United States, Canada, as well as Australian emigration, increases the demand for mercantile marine accommodation, so docks multiply, and she can now number upwards of thirty docks, and two hundred acres of water area. To run through a brief description of the mode in which these are constructed, will but serve to initiate the reader into a knowledge of those in progress, and in prospect of erection. With foundations in rough-hewn granite, fourteen feet below the datum of Old Dock Cill, laid on beech or elm piles, in lengths of from twenty to forty feet, they are carried up battering, in most cases; but in those recently constructed only about twelve or fourteen feet above bottom of footings, and from thence plumb to coping, being faced with dressed granite, arranged so as to key each other, Upon the coping are built warehouses upon Wapping and Stanley Docks, as also upon Albert Dock, that being the first instance, on such an extensive scale, of the kind in this kingdom. The immense strength required in walls having upon them such a mass of material is evidently attained.

The warehouses of Stanley and Wapping Docks are constructed throughout so as to afford the greatest possible accommodation for dry goods, and are therefore fire-proof; this latter being attained by floors laid with rag-stone, upon arches springing from column caps. The whole building is tied from east to west sides by tie rods 1¼ inches in diameter.

To commence with the vaulting, the floor of which is 11 feet below the level of coping of dock wall, the brick piers are built up around cast iron cores, continued to springing of the brick arches which carry the floor. The iron columns supporting the four floors above are all cast on end, with the view of obtaining soundness, and their strength ensured by testing pieces added, which may be detached and placed on proportionate bearings, in the usual manner. The front columns, set back from the wall coping about 2 feet 9 inches (to centre of column), support the front part of the structure, which above them is of brick-work. These are 4 feet in diameter at base, and about 15 feet high. The inner rows of columns are 7 in number, and are one-third the diameter. The thickness of walls at basement are 4 bricks thick, decreasing half a brick on each floor. The total length of warehouses is 630 feet, width 90 feet, and height upwards of 70 feet. Every floor is arched in brick, laid with rag-flagging, iron door-frames and windows are also used, as well as iron doors throughout. Jiggers raise the goods; cranes and hoists are provided, as also hatchways below. The whole is surrounded by a high granite wall, with gothic gate piers at end, and gates on wheel-runners, which renders them easy of motion. Mortar composed of best Halkin limestone is used throughout, with two-thirds of cinders and sand. A brick parapet with panelling surmounts the whole, and a clock with gong, beneath a petticoated canopy is provided The total cost of the Wapping warehouses was £43,000 and upwards. The rapidity with which goods may be discharged and stored may be taken from the fact, that the ship "Leopard," bound from Canton, discharged in Albert Dock (built on the same principle, and with similar accommodation to the Stanley and Wapping Docks,) 6,500 boxes of tea, and 12 packages, from 12. 30 P.M. on a Saturday, to 2. 0 P.M. on Monday (excluding Sunday)—*i.e.*, in 8 hours, upon a calculation made some time ago. These warehouses are all accommodated with hydrants placed in convenient positions, to be used in case of fire.

This brief description will serve to give some idea of those immense storehouses of traffic, which Liverpool within the last few years can boast of. All relating to this extensive port must interest our Irish readers, between whom and it such intercourse exists. We therefore propose to treat of the intended Liverpool and Birkenhead new dock accommodation, in a future Dublin Builder—works that cannot be rivalled for extent and durablity by any of a similar nature in the four quarters of the globe.

HALICARNASSUS.

It is wholesome and agreeable to turn occasionally from the immediate objects of the day to those which actuated some older race—from the track of daily footsteps to scenes of distant interest—from the marvels of modern civilization to the ancient wonders of the world: to waft ourselves in fancy from our land of chequered skies and green pastures to the adust plains of Asia Minor; from the Bay of Dublin to that of Bedroun. The orthography of this word puzzles us exceedingly, and if the Civil Service Commissioners would settle it, we should deem it a civil service indeed, for now it is indiscriminately rendered Bodroum, Boudroum, Budroom, Boodroom, to say nothing of the sliding accentuation sometimes also employed.

In that early period when Carthage, Athens and Rome, stood in contemporary splendour, when the remote shores of our native "Iernis" were frequented chiefly by the Phœnician Spaniards, who have left their stamp on our name and our traditions, Mausolus the handsome son of Hecatomnus reigned in Caria.

On the shore of the beautiful bay where now exist the narrow and dirty streets, with the wretched bazaars of a small Turkish seaport, rose the capital of a polished Ionian nation, the birthplace of Herodotus and of Dyonisius. The castle built in the fifteenth century by the Knights of Rhodes, marks the site of the Royal Palace, while the remains of a large theatre, stone-houses and architectural fragments, exquisite sculptures and antique relics, with which the cultivated gardens and fields are interspersed, bear unmistakeable testimony to the former importance of the place from whence might have been echoed the Homeric strains of Chios, and the beacon light of the Rhodian Apollo may have been discerned from its towers.

We have heard of the revolting ancient practice by which the nearest relative inhaled the breath of a departing spirit, and the devotion of Edward's Spanish Queen has embalmed her memory in the Briton's love, but when Mausolus died, the inconsolable Artemisia, in the extragavance of her grief, drank up the funeral pyre, and spent the remainder of her life in raising to her husband's name a monument of love and honor. It was sumptuous beyond precedent, and ranked among the wonders of the world, so that to every tomb of unusual grandeur the term mausoleum is applied to this day. Artemisia followed the custom of her time in adorning the sides of the tomb with historical subjects, in bold relief, and went still further in gradually surmounting her work with a pyramidal pedestal crowned with the figure of the king in a quadriga or car with four horses. A separate artist was appointed for each side, and a fifth for the statue, just as in Mr. Railton's Nelson Column, the sculptors Bailey, Carew, Ternouth, Watson and Woodington, to whom may now be added Landseer and Marochetti, had their respective tasks assigned.

We cannot, however, pursue this subject further than to state that after the vicissitudes of Natolia, during two thousand and two hundred years under Persian, Macedonian, Roman and Mahommedan rulers, an interest is again felt in its olden glories, and its long buried treasures of art are again the subject of admiration.

An expedition of research was dispatched a few years since under the guidance of Mr. Newton, formerly British Consul at Mytilene, to whose exertions considerable discoveries are due. A cargo of fragments has been received at the British Museum, and are being prepared for exhibition, in extension of the Egyptian, Assyrian, Greek and Xanthian series, already in that great national depository.

Mr. Tite noticed in a paper read recently at the Institute, that the fragments of sculpture represent the favorite subject of an Amazonomachia, and comments on its want of connexion with the history of Mausolus; but if we recollect that a former Artemisia of Caria had assisted Xerxes, with so much ardour as to draw forth the remark that the men fought like women, and the women like men, the circumstance may no longer appear irrelevent.

FALL OF A CORNICE, AND FATAL RESULTS.

Happily accidents resulting from incompetency or negligence in building operations, and attended with fatal consequences, are of very rare occurrence in this city, and when such *do* unfortunately happen, they consequently engross an amount of public attention which is not bestowed on them elsewhere, where they are from their frequency regarded as matters of course. For a lengthened period no accident that has taken place here, has enlisted such an amount of general sympathy, and presented a topic for such universal comment as has that of the fall of the cornice and scaffolding at No. 2, Lower Baggot-street, on the 24th ult., whereby three poor workmen, Michael M'Dermott, —— Dooley, and —— Duggan, were in the midst of life, health and happiness, hurled into eternity.

The coroner, previous to holding an inquest on the body of M'Dermott, on the 25th ult., informed the jury the inquiry would be of a more important character than usual, as it would embrace the question *whether or not there was any negligence or want of skill on the part of the persons who were charged with the responsibility of the building operations* at the house No. 2, Lower Baggot-street; and the following is the substance of what took place during the investigation. The builder, Mr. Brady, of 46, Camden-street, was represented by counsel and attorney, viz., Mr. Frazer and Mr. Charles Fitzgerald, but the wife of the deceased—though likewise as we learn desirous to obtain professional assistance—appears to have been unable to procure it. We are, however, very slow to believe that there is a member of the fraternity who, under the circumstances, would refuse to give his services gratuitously if necessary. At request of the jury, the inquest was adjourned to enable an inspection of the premises to be made, and on their return with the coroner the examination of witnesses was proceeded with. The wife of the deceased testified to her late husband being 32 years of age, and a plasterer by trade, and to his having left home at 5 o'clock on the morning of the accident, from which hour she did not see him until he was a corpse in the hospital that evening; she further stated that she had *three* children and expected a *fourth*.

Michael Glynn deposed to his being foreman to Mr. Brady, and present when the accident occurred. M'Dermott was with other men plastering on the scaffold in front of the house, about 38 feet from the street below; and witness was *on the scaffold about a minute before the accident occurred*. The scaffold was erected about 30 days ago under his superintendence, and was frequently on it, as was also Mr. Brady; believed the scaffold was erected in a proper workmanlike manner; never heard the men complain of it; was inside the house on the top floor when the cornice gave way and carried the men, boards, and everything else with it; the deceased was plastering the cornice when it fell; the cornice was about five feet above the scaffold; the cornice was built of the best materials in proper workmanlike manner; the cornice of Roman cement was formed on a thirteen-inch Carlow flag which projected four inches; the courses of bricks were laid on the flag and cemented over in the usual way, and on the top was a flag of 18 inches wide; the Carlow flag projected in front 9 inches, and the courses of bricks were laid properly, and with due regard to the proper weights and pressures; cannot imagine what caused the cornice to fall, its construction was so good; it struck him that the workmen might have been leaning on it coming up to two o'clock; they do not guage cement about that time, because it would be set before they came from work; we build the cornice strictly according to the plan; the blocking course was sufficient to keep the cornice in its course; the blocking consisted of five courses of brick.

A by-stander, named Benjamin Bradley, who built for himself and the government, cross-examined the witness. He stated that he appeared, in the absence of an attorney for the next of kin, and he cross-examined the witness as to the construction of the cornice, and made allegations to the effect that the cornice was improperly constructed and overhung too much. He produced a large block of the cement work of the cornice.

The coroner said he was glad that there were on the jury several practical builders, who would fully understand the evidence given as to the construction of the cornice.

Thomas Leary, a builder, saw the premises where the accident took place, and the scaffolding several times within the last fortnight; judging from the plan, should say that if it were faithfully carried out, the work should be quite safe.

Mr. Glynn—It *was* carried out faithfully.

The witness pointed out on a diagram the manner in which the cornice was secured, the portions of it that projected, and the portions which remained imbedded in the work, stating that if the cornice was placed as deposed by Mr. Glynn it should have been able to keep its equilibrium, even without the weight placed on the portion which did not project? Would not hesitate to put up such a cornice; never put up the same as this, but did some very similar.

Mr. Bradley—Would you go by that plan after what has happened?

Witness—I should do so.

A Juror—Would you do so?

Witness—I would do so; I would not hesitate to do so if I got directions from the architect, provided the materials were equally good.

Another Juror—Was it not from the work being too top-heavy that it fell down?

Witness—My impression is that it was not; I cannot rationally account for how it fell down.

At the conclusion of his examination, the Coroner stated that the witness had given very intelligent and important testimony.

Denis Byrne, one of the workmen engaged on the buildilngs, said in his opinion, as a working journeyman, that the cornice was properly constructed; could not find any fault with the materials used in its construction; really could not say what was the cause of the occurrence.

Mr. Bradley—And the work was only finished on the previous evening?

Witness—Yes, but not that portion under the cornice; I would not hesitate to go on that scaffolding or go to any height in it; I cannot say what caused the cornice to fall; if the report which I heard is true that the men hacked the flags and broke the bond of union there would be nothing in the world to keep the cornice up; once the cement is broken there is no hold whatever; I have put up heavier cornices than this; during my experience of twenty-one years as a working journeyman for foremen and superintendents, I never saw a more careful man than Mr. Brady's foreman, Mr. Glynn, over scaffolding, and not only over it, but in giving directions to the men as to the manner in which they should lay their stuff on it; I never saw a more cautious superintendent of works than he.

Laurence Geoghegan, a bricklayer in the employment of Mr. Brady, said he was not present when the accident took place; did not know to what to ascribe the falling of the cornice; but saw the deceased about half-past ten o'clock in the morning, before there was much cement on the cornice, hacking at the flag, with a hammer and chisel.

To Mr. Bradley—The hacking occurred at half-past ten o'clock, and the cornice fell after one o'clock.

The Coroner said that this was the most important evidence yet given.

John Lynam, a workman, swore that he was on the scaffolding about half-past ten o'clock on Tuesday morning; Mr. Dooley, who is now dead, called me up to alter the moulds; he was the foreman plasterer; he said—"this man always leaves his work for me to put something to, or take from it;" a portion of the brickwork of the cornice was not sufficiently brought out, so that it required six inches of cement to be laid over it, instead of an inch and a half; the fault of the cornice was that the brickwork did not come out far enough, and Glynn was to blame for this; the workmanship and materials were good enough.

Mr. Bradley—Do you believe that the blocking at the back of nine inches, was sufficient to counterpoise the weight of this mass of cement work which projected forward?

Witness—It would, if the brickwork was built out far enough; I did not see any hacking of the cornice, and if there had been any, I believe I would have seen the chips falling down, as I was working in the drawingroom about half-past ten o'clock fixing the sashes.

It was suggested by the mother-in-law of the deceased, that the wounded man, Johnson, who was on the scaffold at the time, ought to be examined, as he could state whether the cornice fell from its having been chipped—the state of the man, however, would not admit of such.

Mr. Leary was re-called, and stated, that he did not attach much importance to the five inches of cement being on the brickwork, as the weight of it would be about the same as that of the brick if made of the latter; there might be a little difference, perhaps, to give a downward tendency.

J. Carroll, a plasterer—Examined the scaffolding to-day, there is no fault in it; the fault lay in the cornice, it was not properly constructed; there was too much cement in it; it is not usual to put five inches of cement in a cornice; attributes the fall of the cornice to its being too heavy for the blocking; if a person hacked the flag with a hammer it might loosen the bend and cause the fall, but does not see that there was any necessity for hacking the flag in this case. To a Juror—Believed according to the evidence here, that the cornice was not built according to the plan. To Mr. Bradley—Does not think that it was right to put such a mass of cement on a brick wall built the night before.

The previous witness Glynn, said the wall and cornice were built according to the best skill and ability of the workmen. The witness, Carroll, said the skill and ability proved itself, for the cornice fell.

Mr. Frazer said this was a partizan answer. Did the witness mean to say that no accident in a building occurred except through the fault of the work?

Witness did not, and denied that he was a partizan.

Mr. J. F. Rogers, resident pupil of the hospital, deposed to the nature of the injuries sustained by the deceased.

Dr. Kirwan (the Coroner,) said: the evidence having now concluded he was bound to say that he might not have gone into the building question at all; his duty was simply to ascertain the cause of death. But he thought it right, in the interest of the lives of the people, to allow the extensive inquiry just completed to be prosecuted in the manner in which the building operations in question were carried out. Upon that question they had very clear evidence on two or three material points, particularly from Mr. Leary, whose testimony was most important, and he (Dr. Kirwan) felt very much gratified that there were several competent builders on the jury. He left the case entirely in their hands, suggesting merely on the score of humanity—for it formed no part of his duty—that it would be fitting to recommend Mr. Brady to give some protection to the widow and children of the unfortunate deceased, who confessedly, lost his life in the employment of Mr. Brady.

The jury intimated that they intended to commend the widow to the care of Mr. Brady.

The jury, after debating for nearly three hours, and receiving explanations as to the manner in which the cornice was erected from certain of the witnesses connected with the building trade; unanimously agreed to the following verdict:—"We find that the deceased Michael M'Dermott met his death from injuries received by the accidental falling of the cornice of the house 2, Lower Baggot-st., on the 24th July, between twelve and one o'clock, said cornice being then erected, and at the time of the occurrence undergoing plastering by the deceased and other workmen. In reference to the question whether the cornice was properly constructed or not, the jury can come to no satisfactory conclusion, the evidence on the point being contradictory; and the jury desire to recommend the widow and children of the deceased to the humane consideration of Mr. Brady, in whose employment the deceased was at the time he met his death."

At the inquest on the bodies of Dooley and Duggan, the evidence was substantially to the above effect, except that Glynn admitted that he considered the projection of the cornice, nearly 14 inches, was unsafe; and knew that there was a change in the mould but not to what extent. It was also proved that the mould had been altered by one of the deceased.

After a painful investigation the jury found the following verdict:—"We find that the deceased came by his death in consequence of the falling of parts of the house, cornice, and scaffolding of the house 2, Lower Baggot-street, in the course of erection, and we find that the authorities having control, should not permit a thoroughfare under exclusive works of this kind, and we are further of opinion that the deceased might have escaped, if such precautions had been taken."

The Coroner said as to the latter part of the finding he knew that the building operations at Pim's were carried on the whole time with a scaffold over the thoroughfare.

Second finding—"We find that the deceased, John Dooley, came by his death by the giving way of the scaffold caused by the falling of the cornice which he was constructing at No. 2, Lower Baggot-street, and that said accident was caused by the alteration of the original mould, thereby greatly increasing the projection and weight of said cornice, which alteration was made entirely on the responsibility of the deceased, and that all other persons concerned in the building are not in any manner to blame; and further, that we consider the scaffolding to have been perfectly safe.

The jury were then discharged.

[*We believe this case to be one for the special and humane consideration of our readers*, as in their own ordinary occupations they know not how soon a similar occurrence might deprive them of life, and plunge their families into the same anguish of mind under which the poor widows and helpless children of the unfortunate deceased are at present labouring; and we therefore invite, respectfully, their attention to the appeal in their behalf, to be found in another column.]

The Connorree Mining Company.—In the last report of this company's operations we find that the management has been transferred to Dublin, that new machinery has been purchased, that when the railway is open from Wicklow to Gorey a large saving will be effected in the carriage of ores, &c., &c. Mr. John Petherick has reported on the proposed extension of operations, and advised that the expenditure should be confined to the measures necessary for exploring the lode at the pump shaft. The accounts show a balance of £1,394 in the Company's favour, considered satisfactory under the circumstances of the unfavourable season; and a dividend at the rate of 5 per cent., free of income tax, was declared.

Correspondence.

ARCHITECTURE AT THE ROYAL HIBERNIAN ACADEMY EXHIBITION.

Sir,—May I beg to draw your attention to the following paragraph, which appears in the *Freeman's Journal* of the 24th inst.:—

"The architectural drawings are numerous. Some of them are elaborate and highly attractive. Many of them are deficient in that great essential—practical adaptation to their proposed uses as 'working drawings.' This fault does not apply to No. 498, 'A Mansion House Façade,' by our talented young countryman, Mr. O. T. Healy. It is easy to perceive that this gentleman well understood what he was about. Whilst he has produced a beautiful design for a mansion, he has shown that he has kept utility as well as ornament in his mind's eye. The drawing is what may be termed a truly practical one, and does the highest credit to the artist. It would be well if other young aspirants in this department would adopt the example which Mr. Healy has here given. In a future notice we will refer to the architectural and other pictures in the inner room."

Comparing this with your critique (p. 265, June number) on this department of the Exhibition, there is an amount of contradiction impossible to reconcile, a wide difference of opinion on *architectural* merit between the *Freeman's Journal* and the Dublin Builder. What does the reviewer in the *Freeman* mean by saying "the architectural drawings are numerous?" Where are they? Has his lynx eye discovered what neither you, the public, the Academy, or your humble servant could? Again, is it usual to send "working drawings" to an Exhibition? If so, I am enlightened; for I thought they were, as their title proclaims, for "working" purposes only. Again, who is this "talented young countryman", this *rara avis*, on whom—unknown to all but the *Freeman's Journal*—the mantle of Michael Angelo has fallen? I might, perhaps, be deemed impertinently inquisitive if I were to enquire further as to "the beautiful design," which "does the highest credit to the artist;" but I will conclude by saying that there is some truth in the proverb, "*if ignorance is bliss, 'tis folly to be wise.*"

A Reader.

COLLEGE-STREET—THE COLLEGE WALL.

TO THOMAS MOORE, ESQ., COLLEGE-STREET.

Sir—I read your letter in *Saunders* of yesterday morning, on the subject of the contemplated improvements in your neighbourhood, with much satisfaction; and I trust that any opinion or suggestion coming from so eminent a person will have great weight with your fellow-countrymen, especially with the authorities of Trinity College, where you were in your youth a distinguished ornament. You will, I am sure, be glad to hear, and I have much pleasure in stating, that your wishes are likely to be very soon carried out, for the Provost did me the honour to write to me, in my corporate capacity, expressing an anxious desire to co-operate with the Corporation in this most desirable work; and accordingly the city engineer, Mr. Neville, and Mr. M'Curdy, are in consultation as to the best mode of effecting it. College-street will then become one of the most beautiful spots in the city, instead of being, as it is at present, the very reverse, for the directors of the Provincial Bank propose to erect a very handsome building opposite the College wall. I would be extremely sorry to propose anything that could be detrimental to the great University of our city, but I trust that we will ere long see some modification of the "railing in front," which would afford great public accommodation, without being at all injurious to that noble institution. The citizens of Dublin highly appreciated the improvement of Nassau-street, and were grateful for it; those which are now under consideration will be equally valued. I have to apologise for troubling you with such a long letter, and have only to express my satisfaction that our municipal affairs are under such good guardianship.—I am, sir, your obedient servant,

George Roe.

Nutley, 13th July, 1860.

Notes of New Works.

The new station at Sandymount, on the Dublin and Wicklow Railway, has been completed and opened.

The Committee of Prospect Cemetery, Glasnevin, are about having sundry building improvements effected, according to plans by Mr. Patrick Byrne, Architect.

It is proposed to erect a commodious schoolhouse in the suburbs of Dublin for the daughters of the Irish clergy, and as a memorial to Mrs. Whately, wife of the Archbishop of Dublin.

The Corporation for Improving, &c., the Port of Dublin, are about erecting timber beacons on the north side of the river Liffey Channel. Time for tenders limited to 2nd inst.

The Church of St. Jude's at Richmond is at present undergoing great improvements to make it suitable for Divine worship. A new organ has been erected.

The War Department have issued advertisements for the following works in Ireland, viz.: for the erection of an engineer's office at Royal Barracks in this city (time limited to 6th inst.); for plumbing and slating work at Royal Infirmary, Phœnix Park (13th inst.); for slating and bricklayer's work at Old Barracks, Fermoy (same date); for renewing eight embrasures at Charles Fort, Cork District (same date); and for building a magazine and shafting-room at Sandycove battery, Dublin Bay, up to 16th inst.

The foundation stone of the new Presbyterian Church at Rathgar was laid on the 19th ult. by the Rev. Dr. Cooke, of Belfast.

The fittings and furniture of the Council Chamber, City Hall, are open to competition for upholsterers until the 2nd inst.

The Board of Guardians of the South Dublin Union invite tenders from Builders, &c., for new internal fittings, and for rebuilding a portion of the workhouse wall. Tenders to 1st inst. Mr. William Murray, Architect.

Large additions are about to be erected at the Dominican Convent of St. Catherine's, Sion Hill. In the community department will be a new wing containing refectory, corridor, and kitchen offices on the ground storey; in the second storey will be infirmary, noviciate, pharmacy, &c. The two upper floors will contain twenty cells, with corridors, &c. In the boarders' department will be erected a large wing containing schools on ground floor, class-rooms, infirmary, infirmary room, &c. on second storey; and on the third storey large dormitories, dressing-rooms, &c. A transept will also be added to chapel, separated by ornamental columns; under the transept will be the day school for extern pupils. A poor school will also be erected. Mr. Bourke, architect.

Two pair of semi-detached villas, with seven apartments—irrespective of culinary and other offices—in each, and in an elevated position, commanding an expansive view of the bay, "the island," Bray, Shanganagh, the Wicklow mountains, &c., &c., are about being erected at Vico Road, adjoining Sorrento Terrace, Dalkey. Mr. Henry Gonne, proprietor; Mr. J. J. Lyons, architect. The same proprietor has lately completed a large dwelling-house on same property, and now known as Hanna Mount, and some most desirable building sites are available

The Ecclesiastical Commissioners of Ireland are about having the church of Tynan, Co. Armagh, fitted internally, and a vestry-room erected thereat (tenders to 4th inst.); also sundry works executed at the churches of Drumcliffe, Co. Sligo, and Tarmonbarry, Co. Roscommon (tenders to 2nd inst.).

Certain works are to be executed at the churches of Annaduff, Co. Leitrim, Pallasgreen, Co. Limerick, Corclone, Queen's Co., Ballintemple (Dundrum) Co. Tipperary (tenders till 7th inst.), according to plans, &c., by the Architects to the Ecclesiastical Commissioners.

A new parish Church has been erected at Upper Cumber, Derry, in accordance with the plans of the late Mr. Welland. It has nave, aisles, porch, spire, belfry, stained and varnished open roof, and contains sittings for 400 persons. Cost £3000, of which £700 were subscribed by the congregation. Messrs. M'Elwee, Contractors.

The first stone of the new parochial church of SS. Maria and Laurence at Ballytore, Co. Kildare, will be laid on the 5th inst.

A new Protestant church is to be built at Kilmalchedar, Co. Kerry, and the foundation stone has been laid. The site selected is said to be picturesque. Mr. George M'Donnell is the builder.

Forthcoming Italian Operas.—We are informed that the company which is to appear in our National Theatre, on the 10th proximo, will comprise Mesdames Grisi, Viardot, and Gassier, together with Signori Mario, Graziani, Ciampi, and others; names whose mere mention preclude the necessity for comment on the treat in store.

Queen's Royal Theatre.—Miss Emily Wyndham, directress of the St. James's Theatre, London, Miss Lydia Thompson, and Mr. Young, have been attracting crowded audiences during the past month at the Queen's. Any one of the three is "a host," but the combination enhanced the degree of attraction considerably.

The Goldsmith Dramatic Society.—The members of this Amateur Theatrical Corps gave a benefit at the Rotunda in aid of the starving poor of Erris, on the 24th ult., on which occasion the drama of Don Cæsar de Bazan, the farce of Round the Corner, and the comic drama of the Jacobite, were performed.

NOTICE.

We are sorry to receive complaints of the late period at which the Dublin Builder reaches London, and we may say several provincial towns, respecting which, we have instituted some inquiry, and shall be glad of information in any future instance of delay.

Iron Founders, Plumbers, &c.

TO RAILWAY CONTRACTORS, BUILDERS, QUARRYMEN, ETC.

EVERY description of SHOVELS, SLEDGES, HAMMERS, PICKS, Steel, Crab Winches, PULLEY BLOCKS, CHAIN; MASON'S, SMITH'S, and WORKMEN'S TOOLS of all kinds.

THOMAS HENSHAW & CO.,
HARDWARE MERCHANTS AND MANUFACTURERS,
5, CHRIST CHURCH PLACE,
AND
81, MIDDLE ABBEY-STREET, DUBLIN.

CHEAP IRONMONGERY.

A WELL ASSORTED STOCK of BUILDERS' and FURNISHING IRONMONGERY, also GARDEN and WORKMEN'S TOOLS of all kinds, which are offered at the lowest price of the day, for *Cash*, at

EGGINTON & CO.'S (LATE FITZHENRY'S),
No. 160, CAPEL STREET, DUBLIN.

NEW BALANCE ROLLING BRIDGE.
KENNY'S PATENT.

The undersigned beg to call the attention of Engineers and the Public to the above description of Opening Bridge, as now being constructed for the entrance to the St. George's Dock, Custom-house Quay, Dublin, for the Board of Works, which will be found superior to the ordinary Swivel Bridge, both in point of simplicity of Construction and Cost.

Plans and Specifications furnished, and Licenses granted on application to

TURNER AND GIBSON,
PROPRIETORS AND MANUFACTURERS,
HAMMERSMITH IRON WORKS, BALL'S-BRIDGE, DUBLIN.

WILLIAM TURNER,
OXMANTOWN FOUNDRY & IRON WORKS,
103, NORTH KING-STREET, DUBLIN.

Cast-Iron GIRDERS, Plain and Ornamental PILLARS, Moulded and Plain GUTTERS, Tank Plates, Gas Retorts and Pipes, Kitchen Range Work, Millwright, Castings, Balconies, Brackets, Staircase Ballusters, etc., supplied. A large variety of Models for the above in stock.

JAMES SHERIDAN, EAGLE FOUNDRY, CHURCH-STREET, DUBLIN,

Has received Gold and Silver Medals at different Exhibitions for superior Church, Alarm, and Demesne Bells, 2½ tons weight and downwards. In fact, wherever Sheridan's Bells were exhibited, they obtained the highest premium. *All his Bells are moulded by men who served a regular time in that department, and the metals are mixed by his sons, who are perfect in the art of producing the several notes required, either for single Bells or for peals of Bells, "as," for instance, "in the peal of eight in St. Paul's Church, Arran-quay."*

Baptismal Fonts very cheap, beautifully finished, and much in use. Tabernacle and Money Safes, really fire-proof, superior manufacture. Mill and Machinery Castings of all kinds. See his Catalogue of Models. Hydraulic Rams, Pumps, Pillars, Runs, and Eave Spouts, of every size. Church, Altar, or House Railing, plain or ornamental, to any size. Field and Entrance Gates, and all kinds of Wrought-Iron work and Brass Castings, executed at the lowest price.

☞ The highest price allowed for Broken Bells, Old Copper, Brass, Lead, and Metal.

IRON CASTINGS—CASTINGS of every description for Gas and Water Companies, Millwrights, Builders, Plumbers, &c., made at

SEVILLE IRON WORKS, SEVILLE-PLACE, DUBLIN.

WROUGHT IRON TANKS.

THESE USEFUL ARTICLES are suitable for every place where a supply of water is necessary. Their superiority over Cast Iron, Lead, or Stone is manifest, from the fact of their being much lighter, also completely obviating the difficulty in staunching, so objectionable in all Cast Iron Tanks. They are made in every shape and form, to suit the places where they are to be fixed.

Prices from 3d. to 5d. per Gallon, the larger sizes being cheaper in proportion.

HODGES AND SONS,
MANUFACTURING IRONMONGERS,
16, WESTMORELAND STREET, AND 20 & 21,
ASTON'S-QUAY, DUBLIN.

N.B.—Force Pumps, Baths, and all description of Hydraulic Plumbing work executed on the most improved principle.

KITCHEN RANGES, Drawingroom Bright Grates, Fenders, Fire Irons, and all kinds of Builders' Ironmongery. MAURICE BROOKS, SACKVILLE-PLACE, Dublin.

MILNER'S SAFES AND BOXES,
FIRE AND THIEF PROOF.

J. EDMUNDSON and Co. are Agents for the above, and hold a large stock in all the different sizes.

They confidently recommend them as the best protection from Fire and Thieves that has yet been invented.

Milner's Safes have been subjected to the most trying tests, often subjected to intense heat for several hours together, and have uniformly and triumphantly stood the test.

Burglars, after exerting all their powers to obtain an entrance into these Safes, have been obliged to retire disconcerted.

House Furnishing, Ironmongery, and Gas Fitting Warerooms,
34, 35, and 36, CAPEL-STREET.
J. EDMUNDSON AND CO.,
Manufacturers of the Patent Gas Apparatus for Lighting Gentlemen's Mansions, &c.
Sole Agents for Bradford's Patent Washing and Mangling Machines, &c.

Statuary, Marbles, Cements.

ELLIS AND CO.,
PORTLAND CEMENT MANUFACTURERS,
MALONE MILLS,
BLACKSTAFF ROAD, BELFAST.
Sole Agents in Dublin,
Messrs. CAROLIN AND EGAN, 20, EDEN-QUAY.

THE M'ANASPIES, Practical, Plain, and Ornamental Stucco Plasterers, Scagliola and Figure Artists, Staturists, and Asphalte Workers, &c.
PHOTOGRAPHIC AND STATUARY GALLERIES,
31, GREAT BRUNSWICK-STREET, DUBLIN.

CEMENT—ROMAN, PORTLAND, MASTIC, & PLASTER of PARIS.
JOHN CARRICK, 5, MARY'S-ABBEY.

CHIMNEY PIECES—in Italian, Belgian, Irish, and English Marble; Enamelled Slate, and Cast Iron: suitable for Drawing-rooms, Dining-rooms, Bed-rooms, &c. A very large Stock to select from. MAURICE BROOKS, Sackville-place, Dublin.

BEST CEMENTS.
ROMAN CEMENT, PORTLAND CEMENT, and PLASTER PARIS STORES,
10, SIR JOHN'S-QUAY, DUBLIN.

GEORGE HOLMES and Co. are constantly supplied with the above materials of genuine quality, direct from the best manufacturers. Also Sewerage Pipes, Junctions, Bends, &c.

TO ARCHITECTS, BUILDERS, ETC.
JAMES HOGAN AND SONS,
PLAIN and ORNAMENTAL STUCCO PLASTERERS,
CEMENT WORKERS, &c.,
168, GREAT BRUNSWICK-STREET,

Beg leave to state that they will furnish every description of Plaster Ornaments for the Decoration of Cornices, Centre Pieces for Ceilings, at Moderate Prices and on the Shortest Notice.

Country Orders strictly attended to.

KILKENNY MARBLE DEPOT,
26, MARY-STREET, DUBLIN.

Chimney-pieces, Tombs, Monuments, Altars, Tables, and all kinds of works executed in
IRISH AND FOREIGN MARBLE,
Manufactured by
WATER-POWER AND PATENT MACHINERY.

Plaster of Paris.
Roman Cement.
Portland Cement.
Patent Mastic Cement.
John's Patent Stucco Cement.
Keene's Patent Marble Cement.

Of the best quality, to be had of
SALMON RICE, AND CO.
3, ANGLESEA-STREET.
Also Crown, Sheet, and Plate Glass; Fire Bricks, Tiles, &c.; Painters' and Plasterers' Brushes.
Gypsum for Agricultural Purposes
STEAM MILLS AND MANUFACTORY—CROWN-ALLEY.
Established, A.D. 1780.

BARHAM'S RENDERING CEMENT.

FOR internal and external Plastering, Scagliola, &c.—Walls covered in a single working.—May be Painted or Papered on within 12 hours. —Sold by weight.

MANUFACTURED BY
ALFRED G. BARHAM,
CEMENT AND PLASTER WORKS,
BRIDGEWATER.
TESTIMONIALS.

[Copy.] Five Ways, Birmingham, March, 15, 1860.

MR. BARHAM.—SIR—After several trials in various ways, both inside and out, of your cement, I can confidently certify for all you state as to its quality.

I have both papered and painted on the same immediately, and find neither color or paint in the least affected. I am, Sir, yours truly,
(Signed) J. CRESSWELL.

Copy.] Decorative Painting, Gilding, and Paper-hanging Establishment, 119, Duke-st., & 18, Parr-st., Liverpool. Jan. 17, 1860.

SIR—I have much pleasure in bearing my testimony to the good qualities of your "Rendering" Cement. I find that paint will stand well upon this Cement, after being allowed only three or four days to dry.

In another case a wet piece of this Cement was papered with a delicate Pink Glazed Paper, and I find that neither color nor glaze has sustained injury.

Yours truly,
(Signed) p pro ALEXANDER WHITE.
RICHARD S. WHITE.

[Copy.) Bridgnorth, Oct. 25, 1859.

DEAR SIR—We have tried your sample of "Rendering," and find it more than justifies our anticipations. We have tried it raw as a Cement for external work in a very exposed position in a Church Tower, to fix in some Iron Cramps in lieu of lead, and find it answer perfectly; also for cornices; also mixed with hair mortar as gauged stuff for forcing work; and in several other ways. When anything stirs, we will apply to you for some more, as we find it better and cheaper for gauged work than any we have ever had.—With respects, Sir, we remain yours very truly, (Signed) JOHN PICKARD & SON.

CENTRAL DEPOTS.

LONDON—A. J. TATHAM, 14, South-wharf, Paddington Basin, W., and Purfleet-street, Earl-wharf, Blackfriars, E.C.

LIVERPOOL—GEORGE F. CHANTRELL, 6, 8, and 31, Hatton-garden, 60, Soho-street, and Bank-quay, Warrington.

Building Ground, &c.

BELMYRA, DUNDRUM, CO. DUBLIN.
TO CAPITALISTS, BUILDERS, & OTHERS.

MOST DESIRABLE BUILDING GROUND TO BE LET.—This Estate, containing 150 Acres, situated within half a mile of the Dundrum Railway Station, has been laid out in Lots for Building. The position is admitted to be the most beautiful in the environs of Dublin, and is particularly well circumstanced in every respect, commanding views of Killiney Hill, overlooking Mount Merrion, City and Bay of Dublin, &c.

A railway station in the centre of the estate is in contemplation, bringing it within ten minutes' drive per rail of Harcourt-street.

A map of the lands, showing them laid out in building lots, can be seen, and every information obtained, at the offices of Edward Henry Carson, C.E., Architect, &c., 25, Harcourt-street.

THE NEW BUILDING GROUND at RATHGAR, to be called KENSINGTON-SQUARE, is now ready for setting. Lease, 900 years. Several lots are already let. Plan and particulars at
BENTLEY & SON'S,
110, GRAFTON-STREET.

N.B.—A few lots for Cottages in KENILWORTH-AVENUE, adjoining the above.

TO CAPITALISTS AND BUILDERS.

TO BE LET for BUILDING, the Ground round Wellington-square and in Hatch-street, the Maps and particulars of which may be seen at the Offices of JOHN LOUCH, Esq., Architect, &c., 15, Molesworth-street, Dublin.

TO BUILDERS.—TO BE LET, in RATHGAR, on the Roundtown-road, about 500 Feet of BUILDING GROUND, 260 feet from front to rere, at 4s. per foot. Also, in Rathgar-avenue and Beauchamp-avenue, 2,000 feet, at 3s. per foot. Lease 999 years. The situation is unquestionably the best in the suburbs of Dublin. Apply to Dr. BEAUCHAMP, 115, BAGGOT-STREET; or to F. ARMSTRONG, Builder, BAGGOT-STREET.

The Dublin Builder.

Vol. II.—No. 21.

PASSING REMARKS ON LONDON BRIDGES.

WHAT a lecture on science might be read from the bridges of London; and to the simply observant and reflective how much do they suggest that is noteworthy. The means of crossing deep rivers must have been resorted to in very early times, and mention is made of a kind of draw-bridge over the Euphrates at Babylon, which was closed at night to prevent the marauding forays of the turbulent Assyrians; but bridge-building in its full masonic form must have commenced with the Romans after the invention of the arch. The structure thrown across the Danube by Trajan, and figured on his column at Rome, consisted of stone piers with a wooden superstructure of segmental ribs supporting the roadway. The Tiber was crossed by eight bridges in and about the capital at a very early day. England may not now possess a Roman example, but there can be no doubt that our early conquerors introduced their own forms and modes of construction; some abutment piers supposed to be of their age were discovered in preparing for the new bridge over the Ouse at Stony Stratford. Dion Cassius says the Gauls, about A.D. 44 passed a bridge on the Thames, but we should incline to think it must have been at some point above London. Snorro Sturlesoni mentions a bridge in 1008, and Stowe says the monks of St. Mary Overies were the first builders. In 1176 Peter, the curate of Colechurch, commenced the great work, which after a labour of thirty-three years was opened for public use in 1209. It was 926 feet long, had pointed arches of stone, a central drawbridge and a chapel in which the remains of its architect were afterwards interred. There was a fortified gateway at either end. It was originally only 20 feet wide, but in those days the traffic was chiefly, if not wholly, confined to foot passengers and horses,—the porter drays, the coal waggons, the highly-piled loads of hops and general merchandise which mingle with the fashionable chariots of our day, were all unknown. The throng of passengers generally attracted the cupidity of the citizens, and upon the starlings were erected shops and other buildings, leaving but here and there free parapets from which a sight of the river could be obtained. These habitations were lightly constructed, and when in 1213 a fire took place, the flames spread so rapidly as to enclose a vast assembled throng, and so overwhelming was the danger and panic, that three thousand people are said to have been destroyed.

Let us, however, say no more about bridges as they were, but proceed to take them as they are, for which purpose we may most conveniently commence with Battersea, and follow the stream in its downward course. The rusticity of Battersea-bridge—a wooden expedient of some dark though, it may be feared, not distant age, and whose reminiscences may be classed into accidents on the river and high tolls on the road—together with the primitive appearance, might lead the casual observer to suppose it the one passed by the aforesaid Gauls in the first century.

Next in our course is the Suspension bridge at Chelsea, erected by the Government from Mr. Page's design. It is the lightest and most ornate work of the kind, perforated panels of cast iron being extensively used in the unstrained surfaces. There is something of Moslem character in the design, and every part seen from the very surface of the water being of iron or painted in a similar way to the parts which are of that material. The general effect is one of airy prettiness. It was commenced in 1850 and finished in 1857, giving access to the newly-formed suburban park from a point near the hospital of the military veterans.

At a few hundred feet lower down the stream is the railway bridge just on the eve of completion, for carrying to the new Victoria station at Pimlico the lines of the Brighton Companies' Crystal Palace and West End branches. The energy displayed in British commercial undertakings is well seen in the rapidity with which this work—commenced only last year—has been brought to maturity. It may be termed a plate-iron bridge of four arches, with open spandrils on piers of stone, and there are two land bays without arches carrying a platform over the public roads on each side of the river. Having said that this bridge has four arches, it follows that like the great Britannia tube across the Menai—its central pier is in the midstream; but in neither of these cases has the omission of a void where the current is necessarily most active and powerful been a matter of caprice, for in the great work of Robert Stephenson Nature settled the question by the little rock on which the pier was raised, and at Chelsea the governing cause is almost as apparent. The engineer of the suspension bridge divided the total span into four parts and placed the piers at points equi-distant from the centre and the respective banks, then as the railway passes at so short a distance lower down it was necessary to keep the piers opposite to those of the neighbouring work, and to introduce the requisite additional support in the middle.

Vauxhall Bridge, erected by James Walker between 1811 and 1816, is an unpretending, business-like, and well-built structure, in which the designer seems to have kept in mind the great object of a return for the capital employed rather than a display of his own powers; yet the work is an evidence of very great ability, comprising nine equal arches of 78 feet span, composed of cast-iron ribs on stone supports, showing a great improvement in point of lightness, and affording the advantage of a nearly level roadway.

It is impossible to proceed without a momentary notice from this spot of the vast Reformatory Prison or Penitentiary at Milbank, on the Middlesex shore, for prisoners undergoing commuted sentences. It was erected by Sir Robert Smirke, upon the so-called Panopticon principle, giving to the central station the visual command of every corridor and court. Its multangular plan, and the conical roofs to the numerous turrets, give to the exterior a peculiar and somewhat foreign expression. In the distance rises the noble Victoria Tower, Westminster Abbey, and the Church of St. John, while on the right bank of the stream stands the venerable Palace of the Archbishops of Canterbury at Lambeth. From the quay in front of this palace the most perfect view of the Parliamentary edifice is to be obtained, and at just such an angle as to embrace the river front and south return together, with the higher portions of the Abbey, while the smooth level surface of the water lends repose and imparts height, which with regard to the object under notice is of special value.

Although sanctioned by the custom of a thousand years, it was, perhaps, a mistake to pay too much attention to the old Westminster levels, and the new building cannot be seen without a great sacrifice of dignity from any position but the one just named. It was most injuriously viewed from Old Westminster Bridge, and if that building were included in the prospect, its great rise and curved parapet acted most prejudicially. Any bridge in such close proximity must have this effect to some extent, or be itself spoilt, and the convenience of the navigation be invaded.

Labeyle's Bridge, erected between 1738 and 1747, has after little more than a century been superseded by the one now in progress and in part opened, from the design of Mr. Page. It is in seven arches of cycloidal curvature, diminishing from 120 feet in the centre to 94½ feet in the extremes. They are constructed with fifteen ribs of cast and wrought iron on piers of somewhat novel contrivance, but ostensibly of stone, and the work is expected to exemplify in a marked degree the progress of economy in such undertakings.

The name of Brunel now engages our attention in the Hungerford suspension foot bridge, which like all his works shows great skill in design, and that constructive lightness to which his attention was so largely and beneficially directed. The principle of suspension is, however, unsuited for heavy traffic, owing to the great degree of motion to which the parts are subject, and the effect of wind in increasing that motion to an inconvenient and occasionally dangerous extent. This is quite a modern bridge, but innovation is already close upon it: pile drivers are at work about its piers, iron cylinders are sinking gradually into the earth, and the diver in his casing of mail, more formidable in appearance than the armour of the battle field, is seen at times to emerge, and testify somewhat of the means by which these subaqueous works for the Charing Cross Railway are carried on.*

The man who took the boldest grasp of the public mind in the subject to which this paper relates was John Rennie, a native of Phantassie, in East Lothian, who settled in London in 1783. After giving evidence of talent as millwright and in other engagements, he was employed on Waterloo Bridge commenced 1809 and finished in 1817; the length being 1242 feet is greater than any neighbouring example, and is taken up by nine elliptic arches and their dividing piers. These latter are decorated with coupled columns as had been previously done at Blackfriars, but the original mind of the contriver was grandly shown in the arrangement of the approaches. Taking the Strand for a datum level he extended the bridge by a series of land arches, crossing at a considerable elevation the old Belvedere road on the Surrey bank. The bridge is of granite, and so noble and striking in effect that Canova, the sculptor, pronounced it to be worth a visit from the remotest corner of the earth.

We now approach, and let it be with due respect—for though not first in size at least in age he stands the pontine father of the Thames — Blackfriars. It was designed by Robert Mylne, an architect of celebrity in the last century, who studied at Rome. It is a very handsome form presenting the earliest approach to the flattened or elliptic arch, and is altogether an ornament to the noble water it bestrides. This was built between 1760 and 1771 for a body of subscribers who had the privilege of a toll for only nineteen years. There are nine arches, and the central span is 100 feet. Portland stone was employed, but the piers have since been cased with granite. The road was judiciously extended for some distance at the ends, but not over any cross street, a sort of recess or square being formed through which the elevated causeway passes.

---

* The suspension chains and roadway of Hungerford Bridge have been purchased for £5,000 by the Clifton Bridge Company, subject to the further cost of taking down and removal. The appropriation is one than which nothing could under the circumstances have been happier, as the destruction of one of Brunel's designs is thus made subservient to the completion of another.

While Rennie was conducting the works at Waterloo he was also employed from 1814 to 1819 on the Southwark bridge, and a very noble specimen of his genius it presents. He was beyond question the leading engineer of his day, albeit of a pre-tubular and box-girder age, ere the requirements of the railway system had developed our present exact and intimate acquaintance with the properties and management of malleable iron. Southwark bridge being only 708 feet long, is the shortest of its class, has stone piers and three magnificent arches of which the centre spans no less than 240 feet. They are segmental, and formed of a series of eight ribs, which were prepared at the works of Mr. Walker, a gentleman whose name was long familiarized by its constant appearance on those humble but useful implements of the laundry—flat irons. Great attention was given, as in the Waterloo example, to the ascents of this bridge, which are adjusted by long inclines to the adjacent levels. It was erected for a company of proprietors, but from its situation at a short distance from two open bridges, and the absence of any great artery of traffic to act as a direct feeder, it has not proved successful.

The great fund of experience which Rennie has acquired in the works just noticed and in others of the first magnitude, such as Ramsgate Harbour, Plymouth Breakwater, and the Bellrock Lighthouse, was brought to bear upon the new London Bridge, the very chef-d'œuvre not only of the man but in its way of the nation itself. The design is eminently characteristic and expressive, severely simple yet not barren, stable yet not heavy. It proclaims the beauty of an exact symmetry, and we recognise in it a masterpiece of skill. What an extraordinary advance upon the previous occupant of the spot—an advance which represents six centuries indeed, but still how great the onward stride. Instead of that which was hardly more to be regarded as a bridge for crossing the stream than as a dam for impeding the free current, causing falls and eddies, destructive to the inexperienced navigator and dangerous to the skilful, we have that nice apportionment of void and solid which causes no abrupt check to the flood, yet imparts the quality of repose to the superstructure.

The idea that would seem to have been ever present in Rennie's mind concerning level roadways and extended approaches was carried out in its amplest form in this instance, especially on the City side, where the old level of Thames-street forms a sub-way under the land approaches, while the bridge falls into the superior levels of King William and Cannon streets. This noble granite bridge is 928 feet in length, is 58 feet wide, and has five elliptic arches, giving a span to the centre of 152 feet, to the two adjoining arches 140 feet each, and to the extreme openings 130 feet each. The cost may be roundly stated at two millions, but a vast outlay has been also incurred during the subsequent period in remodelling and adjusting the more important thoroughfares and avenues of communication.

It is, perhaps, the last bridge of the purely masonic and monumental character of which London is likely to be the scene, but it will be long, we trust very long, before any antipodal wanderer shall behold it in a shattered and crumbling form, yet how soon might a single oversight have caused its destruction to follow the triumph of its pristine perfection. Inconceivable as it may appear, a course was pursued in removing the mere means employed in the erection of this stupendous edifice—in comparison with which the worth of every foot of timber used should have been weighed as nought—that for a while threatened the stability of the vast fabric. The withdrawal from the subsoil of the river of the piles used for the coffer-dams, which ought to have been cut off and not extracted from the river bed, caused a derangement of the foundations, which after giving rise to intense alarm and originating settlements in every pier of from six to ten inches, fortunately ceased, and we hope for ever.

A work more singular in its nature, more difficult in execution, and calling forth in an unexampled manner the faculties of invention, of energetic resolve, and untiring perseverance, is that monument of Sir Mark Isambert Brunel—the Thames Tunnel at Rotherhithe; but it is hardly within the scope of this paper, which has already exceeded our intended limit.

Within little more than a century a sum approaching to eight millions sterling has been expended in securing access between the two sides of the great metropolitan stream, great talent has unquestionably been fostered and called forth, but in some instances there has been an absence of those reasonable deductions which come under the name of ordinary foresight or common sense. Nor is it to be denied that, with the numerous bridges just passed under review, London and its suburbs are in a state bordering on destitution with regard to really available objects of the kind. Down to the middle of the last century no other than Old London Bridge existed within several miles, although at this period such a want must appear to have been intolerable. In 1788 Parliament made a grant for the bridge at Westminster; that at Blackfriars, built as we have seen at private expense and rendered public at the end of nineteen years, was thus acquired in 1770, since which period no augmentation to the number of free bridges has been made, if we except the one at Chelsea where the toll for foot passengers is not charged on Sundays. In this state of things, therefore, the poor, the wayfarers, and children are denied the means of passing, and are frequently found awaiting the aid of some considerate hand. London Bridge is most densely thronged with traffic of every kind, and but for the recent admirable classification which separates the heavy and slow from the light and rapid, it must have proved altogether inadequate, and a widening was at one time mooted. It would indeed be most difficult to effect any serviceable modification without incurring a great outlay and as great disfigurement; but the proximity of Southwark Bridge points to the propriety of laying that structure open as a public auxiliary, with a suitable widening of the way to it from Cheapside. In fact, all the bridges are wanted, as may be inferred from their having, to so great an extent, originated in the very conviction of their necessity; but their usefulness is counteracted by a toll, which, as far as the railways on the south side are concerned, will be to a great degree obviated by their extension to Pimlico and Charingcross. The Thames Tunnel, again, though too costly to be profitable, would, if thrown open, afford a vast boon to the public, and we regret to hear a rumour of its appropriation to railway purposes, as being a degradation of this noble work to meaner uses. The public who contributed to its completion ought to have a priority as purchasers, and we further think that a subaqueous way for trains might be effected on the tubular principle, sunk by dredging to the necessary depth, at a cost not to be compared with that of the original, and with certain advantages in respect of locality and general convenience.

Beneficial Effects of Ventilation.—There is no disguising the fact that among the many deficiencies of the present time none stand out more conspicuous than the neglect of ventilation. It would be unnecessary to refer to the fearful results arising from the apathy displayed, were it not that evils once past are too often forgotten until reminded when too late by their return. It becomes every one who seeks to add something to the general good, and desirous of adding to the duties of life, not to lightly pass any means to secure its comforts and health. Such are daily made known in the means provided. The system is not only efficacious, but simple in construction; in no way preventing the adoption in sitting-rooms, bed-rooms, or any other part where a free circulation of air is required. Was it only in theory such matters were made public, much objection might be raised; but having been proved a positive reality in effects produced, it requires but little recommendation to add to its necessity in all cases where health is sought to be promoted and personal comfort enhanced. The ventilators which are considered the most effective, and to be obtained at the smallest cost, are those of Mr. Moore, in Fleet-street, London.—*Morning Herald.*

Carlow Cathedral Church.—The decorations of the porch of the principal entrance to this beautiful edifice has just been completed by Mr. P. Lalor, of this town, and we feel great pleasure in saying that on his taste and artistic skill the work reflects the greatest credit. The groined ceiling is wrought in French white; moulding ornamented with ultramarine and gold roseats, the panels having a small stile round, with an ivy scroll midway on either; the bosses are picked in white and gold, and the terminals in suitable colours. The walls are decorated in light pea green, representing tapestry, with fawn colour borders in each corner, having ornaments of a darker shade around the arches in a shamrock scroll. The lower portions of the walls, measuring 6 feet from the ground, are formed into panels, each curved at the top, over which runs a pointed fretwork, hanging over it, also, another border of *fleur de lis*, through which shamrocks are entwined. The decorations of the whole pleasingly harmonise with those of the interior of the church, and are, as we have already said, executed in the highest style of art.—*Carlow Post.*

Art in the Arctic Regions.—The American Protographical Society, at its last meeting, made arrangements to send a photographer with the expedition of Dr. Hayes, which sailed for the Arctic regions at the end of June. The project must meet with favour from all concerned, and, if carried out liberally, will be productive of a great deal of good. If good photographic views are brought back, we shall be able to study Arctic geology, natural history, and even the climate, all by our cheerful firesides. A photographic view always shows more than any pencil sketch, and we are sure it tells "the truth, and nothing but the truth." The camera takes in *everything* before it; and it may be that the Arctic photographs will enable us here to discover important facts which would escape the attention of the traveller chilled with cold, however zealous he might be.

THE DEVELOPMENT OF OUR RESOURCES IN GRANITE, SERPENTINE, AND MARBLE.

THE brief notice given at page 303 of the lectures delivered at the Museum of Practical Geology in London, by Dr. Melville of the Queen's University, may call two circumstances to mind—viz., that Ireland contains minerals of great beauty and applicability for building purposes, and that there exists in the sister metropolis a public institution in which the products of our quarries are already, to some extent, exhibited, and where they may be hereafter displayed in a much more adequate and general way, their varied properties and qualities be laid open to the public eye, and brought into that fair range of competition which it will be the constant object of this journal to advocate and secure for every useful product of this country coming in any reasonable way within its scope and province. When the granite of China, brought as ballast in the holds of vessels, becomes an object of commerce on the Royal Exchange, it is difficult to conceive why the granites of Ireland should remain unemployed for any and every use of which they are directly susceptible.

The "Guide to the Museum," a very serviceable little work, informs us that "the most extensive granite district in Ireland stretches south from Dublin, through the counties of Wicklow and Carlow, into Kilkenny; it occurs on the south-eastern coast of Down and around Newry; the range of the Mourne Mountains is granite, which again appears in small and isolated protrusions in Derry and Tyrone, and in Cavan. In the western portion of Donegal there is a large extent of this rock, which here partakes of a gneissose character; and again, in the west of Galway, granite covers a considerable area. The granite of the Wicklow range is the most extensively used. It varies in its quality, that near Kingstown being coarse and hard, while that from Ballyknocker or Golden Hill is much finer, and therefore fitted for ornamental work. The granite of Down is of a darker colour, and finely crystallized. It is extensively quarried at Newry, and sent by water to the north of Ireland. The Galway granite is of a reddish colour, containing large crystals of flesh red felspar. That of Mayo is of a dark bluish grey colour, while that of Tyrone is reddish.

"The Irish granite averages 170 lbs. per cubic foot, its extreme weights being 143 lbs. and 176 lbs. After 88 hours' immersion in water it was found that a cubic foot of the granite of Newry and Kingstown absorbed about a quarter of pound, that of Carlow nearly 2 lbs., and the granite of Donegal 4 lbs. of that fluid."

The variety afforded by this island, therefore, takes a range, as to hardness, permeability, texture, and colour, that may meet very opposite demands.

The growing attention to colour in architectural works seems favourable to the use of Irish serpentine, some specimens of which are found at the museum, and "the Guide" observes, that "under the head of marbles we find the serpentine rocks frequently included. These, however, differ widely from the limestone rocks, being compounds of silica and magnesia, with adventitious admixtures of alumina, iron, and other substances. The west of Mayo and Galway are remarkable for their serpentine rocks, which afford the beautiful variegated green and white specimens exhibited in the screen, pilaster, and columns.

"This green Connemara marble, as it is usually called, is obtained at Ballinahinch, in Galway; the most valuable quarries are situated near Clifden, from which this fine material is largely exported.

"It is a common error to comprehend every stone which will polish under the name of marble, and several varieties of syenitec rocks produced in Ireland are commonly so called. Syenite much resembles granite—the former, however, consisting of felspar, hornblende, and quartz, and the latter of felspar, quartz, and mica; they pass from one into the other by almost insensible degrees."

With regard to basaltic rock, attention may be called to its applicability, by the process of fusion, to many ornamental purposes. "Messrs. Chance, Brothers, of Birmingham, have adopted the process of melting the Rowley rag, a basaltic rock, forming the plateau of the Rowley Hills, near Dudley, South Staffordshire, and then casting it into moulds for architectural ornaments, tiles for pavements, &c. Not only the Rowley rag, but basalt, greenstone, whinstone, or any similar mineral may be used. The material is melted in a reverberatory furnace, and when in a sufficiently fluid state, is poured into moulds of sand, encased in iron boxes, these moulds having been previously raised to a red heat in ovens suitable for the purpose. The object to be obtained by heating the moulds previous to their reception of the liquid material, is to retard the rate of cooling; as the result of slow cooling is a hard, strong, and stony substance, closely resembling the natural stone, while the result of rapid cooling is a dark brittle glass."

Of proper marble or limestone, the work to which we are indebted for our extracts says—"Ireland is rich in marbles. Her limestone formations extend over a central plain, 120 miles east and west from Dublin to Galway Bay, and about the same distance north and south, their greatest elevation being about 300 feet. The more valuable quarries are in the counties of Kilkenny, Carlow, Galway, and Mayo. From these several varieties of marble are raised, especially the black marble, next to which in importance are the dove, mottled grey, and white marbles. The Galway marbles are well known, but the beds in the quarries are usually thin, and there are but few of them which are fit for working; still fine blocks can be raised. It is quarried principally at Menlo, on the banks of Lough Corrib, the cost of obtaining it being greatly increased from the difficulty of getting rid of the water which flows into the quarries from the lake, the beds being near the surface level. White marble is obtained in Connemara and in Donegal; the limestone of the former district is hard and fine, and is the strongest which has been found, while that of the latter is so exceedingly coarse, that it cannot be used for fine work. The white Connemara marble cannot, however, be procured in large blocks free from streaks, which pass through the blocks parallel with the beds. These counties also produce the bluish white and pink tinted marbles.

"The principal quarries are the following:—

Black Marble,	Kilkenny, Galway.
White Marble,	Churchtown, Doneraile, Kerry, Tipperary, Connemara, Donegal, Churchtown, Kerry.

Coloured Marbles,	These are scattered over all the districts in which the limestones occur.

"In chemical composition these marbles may be regarded as carbonates of lime, containing, in addition to carbonic acid and lime, magnesia, silica, and alumina, in small but varying proportions. The colouring agents are generally salts of iron; but organic matter exists in large quantities in many of the marbles, determining, at the same time, the colour and the general characteristics."

It is gratifying to know that a public depository is thus open to the owners of mineral wealth, but we would presume to offer a word of exhortation to more active efforts for developing the resources of native industry, and we point suggestively, therefore, to the organization of an export agency, on a scale commensurate with the importance of its purpose, and requiring the combination of many interests.

We would, moreover, point to the substantive character the international exhibition of 1862 is beginning to assume, and to the opening that may be thus given for the display of natural products, and especially to specimens so wrought upon as to display their qualities and peculiar adaptation.

It is gratifying to add to the foregoing, that the new museum at Oxford owes its design to the architects of our museum here in Dublin, Messrs. Deane and Woodward, and that the granites, limestones, serpentines, and marbles of this island are constructively displayed at Oxford in columns, capitals, corbels, and such-like features.

THE PRÆRAFFAELLITE MOVEMENT.

In suggesting this as a suitable topic for discussion by the members of the Ecclesiological Society, the president (A. J. B. Beresford Hope, Esq.,) remarked that, "it would take a long time if he were to discuss what was the origin of the Præraffaellite movement; but he held in his hand a periodical, which appeared about 1850, and in the first instance bore the name of the "Germ," but afterwards took the less precise title of "Art and Poetry." His attention was first drawn to it by Mr. Dyce, who asked him if he had seen a book by the young men who called themselves the Præraffaellite brethren. He said that he had not, but soon afterwards became possessed of the volume. At this period Mr. Millais' picture of the House at Nazareth was exhibited, and was the first published challenge of the new school, and was followed in subsequent years by several well-known successors. Præraffaellitism, from its first starting, had two distinct principles at work: one was a sort of mysticism, half-hieratic, half-theological, and withal chivalrous; but the other phase of the movement was a most strong and determined realism—a determination to paint nature absolutely, as naturally, or more naturally, than nature itself. When he said so, he meant that nature as seen by man was a compromise; nature must appear to every man in a different aspect. The very keen, sharp-sighted man saw a quantity of objects, whereas the short-sighted man was obliged to sum up and take general results; the minuter features did not present themselves to him. He saw just the facts of form and colour, but the details to him were unknown. So the various atmospheric effects of the same scenes were seen by different persons in different aspects. Painting accordingly best fulfilled its duty to nature by embodying the sum total of this compromise. Again: no representation could be representative of nature which did not deal with that chiaro-oscuro which was a principal element in all nature. The Præraffaellites were determined to sum up every detail, and from the accumulation of these details they expected to form a natural result. Mr. Holman Hunt's last painting, "Our Lord discussing with the Doctors," was looked upon by the Præraffaellites as the triumph of their art. All who had seen it had been struck with the perfection with which the details were worked up. It was wonderful for its minuteness; but then, was it so grouped that the Saviour of the world was made the central figure? Was it not a conglomeration of wonderfully studied models? Where was there in it the glorification of one figure? There were painters of old, in Holland and elsewhere,—Van der Helst, and others,—who knew how to combine that attention to minutest details, which was the boast of Præraffaellitism, with a perfect handling of chiaro-oscuro, and mastery of grouping. To be sure, they sometimes exercised their powers, as Gerard Dow was fond of doing, upon a battered brass pitcher. But upon Præraffaellite principles no one ought to object to the most careful treatment of a battered brass pitcher. For his own part he had no wish to depreciate them. Mr. Hunt's "Awakened Conscience" was a picture deserving of the highest praise. But as a fact the mystic aspect of the school had yielded to the realistic. Assuming then that intense realism is the present Præraffaellitism, is that peculiar style of painting the natural correlative of the Gothic movement? He humbly contended that it was not. He admitted it had done a great deal of good by the resistance which it had opposed to the slovenly and swaggering styles previously in vogue: but it was one thing to do good as a protest against what was wrong in academic painting, and quite another thing to be that which was absolutely good. He thought that Præraffaellitism had done good, but Præraffaellitism in itself surely was not the highest aim of art, and most especially not the highest aim of that religious art whose handmaid Gothic architecture was. Surely the very essence of Gothic architecture was the imaginative scale which it created—the production of the idea of infinity within limited space: while in Classical architecture finite and measured dimensions were the artist's aim. How then could the minute realism of Præraffaellitism accord with that architecture which was essentially imaginative and spiritual? A controversy had some time since been carried on between distinguished professors of Pointed architecture as to whether the representation of foliage should be naturalistic or conventional, and he thought he had the right to claim those who supported the latter doctrine (without himself pronouncing an opinion on the question) as agreeing with him in his view of Præraffaellitism. But in another aspect of the matter, in reference to the direct connection between architecture and the graphic arts in the representation of the human form as a compromise, as all nature was, they surely should seek to embody ideal beauty; they should particularly, in representing figures of sacred personages, aim at that ideal beauty in which the Greeks were so successful, although imperfectly successful. In mediæval art on the other hand the beauty of purity and religious expression was present, although the technical grace of antique models might be absent. Accordingly he called on the art of the present to combine these excellencies. The imperfect beauty of the female figures which Præraffaellitism offered was accordingly a defect in its practice against which he protested. He had been always puzzled at the strange facial lines which that school was in the habit of employing, but in looking at a dialogue on art in "Nature and Art" he had discovered that it has from the first and purposely endeavoured to "break the facial line of the Greeks." He protested against this principle. The Præraffaellites were very fond of subjects from Arthurian legends, and rightly so, but if they would paint Guenevere he called on them to represent her like Helen and not with a face which they might see on the first passer-by in Conduit Street. Still they were under a great debt of gratitude to Præraffaellitism for knocking on the head many academic traditions of rather a stale character. But as a believer in the spiritualism of Gothic art he looked for that school of painting which was a true correlative of that movement not in Præraffaellitism, but among painters like Dyce and Herbert in England, and on the continent in Overbeck, and among painters known as the Dusseldorf school in Germany.

Mr. Burges said it struck him that the Præraffaellites had tried to do in painting all that the Cambridge Camden Society did in architecture. They went back to the first elements just in the same manner that architects were referred to the old churches; they kept to nature as the chairman wished architects to keep to old churches. The movement of the Præraffaellites began much later than that of the gothicists, Architects have by this time learned to design, but painters are yet in their tutelage. We should accordingly now discourage panel-painting, and encourage wall-painting. In the mean time their best artists were going on as well as possible. Rossetti, Hunt, and Millais, still adhered to nature, and were improving: he expected that the world would be delivered by their labours from the conventionalism under which it had been bound. He hoped that the Præraffaellites would break the facial line of Greek face which the president so much admired, and thought that if the Venus were turned into flesh and blood, she would not be such a creature as any one here would admire.

Mr. Seddon remarked that it seemed to him they often made a great mistake as to what the Præraffaellites intended, and what their tenets were, viz., a protest against what was termed "slop." He thought the Præraffaellites, when they started their movement, meant to say that they were entering a protest against the system of the painters in existence at that period; they determined to paint well whatever they did paint, and they said they would go to nature for their types. He thought that what the Præraffaellites meant as regarded the old painters whom they professed to follow was, not that they thought the works of Giotto and others perfect, and that they should be copied in all respects, but they thought that there was more of art in them than in the works of Michael Angelo and his followers; they did not mean to say that they would not adopt the greater knowledge of other men.

Mr. Gambier Parry thought that Præraffaellitism should be called Pre-Reynoldism, because it was a return to the pure system of colouring. What was meant by originality? It was going back to nature. Præraffaellitism had done that. It had gone back to a pure system of colouring and to nature. Study was the basis of all art. And in working out the principles of painting as well as of architecture, he did not see why they should not work out a new style by going back to true principles.

Mr. Street wished to join his word in favour of the school of Præraffaellitism. He thought the chairman had a little misrepresented the real result of Præraffaellite art. The main object of the school was to do everything in the most natural manner. He could not admit that there was any incongruity in defending conventional foliage in architecture, and yet upholding the connection between the Gothic and Præraffaellite movements. He defended Mr. Boyce and Mr. Brett among Præraffaellite artists from the charge of over minute copying. After referring in terms of praise to the landscapes of Rossetti, Hunt, Millais, and other painters of the same school, Mr. Street said he thought the Præraffaellite school had been developed in precisely the same way as they had developed the Gothic movement. Such a man as Pugin (though he might not be admired in all things) taught them to think of nothing but truth in their art, and that they should do in architecture what was true and natural; and that was what seemed to be the object of the Præraffaellites. The work of the Præraffaellites seemed to have been the natural accompaniment of the Gothic movement. The Præraffaellites had a most enthusiastic love of Gothic architecture, and that surely ought to be a consideration in their favour. The only artistic memorial in favour of Mr. Scott's design for the Government Offices proceeded from a body of Præraffaellites. He expressed his own distaste for the Dusseldorf school, as being a mere dead reproduction of an old form of art. The Præraffaellites were decried for minute details; but if the walls of cathedrals and public buildings were given up to them, they would soon lay aside this fault. Instead of paying two guineas a foot for painted windows, patrons of art should encourage the Præraffaellites by commissioning them to paint their walls. The enthusiasts of the school had shown the determination to succeed in their art, by painting, gratuitously, the walls of the Oxford Union.

The Rev. W. Scott remarked that as to the matter of chiaroscuro, and to the last work of Mr. Holman Hunt, one of the most striking things was that on visiting tropical climates the atmospheric effect in perspective did not exist. The objects presented themselves in a much flatter way than was the case in this country, and that might account for the want of atmospheric effect in Mr. Hunt's first picture, as well as in his Scapegoat. In a very warm latitude things presented themselves in very flat plane. But it might be a mistake to introduce that kind of treatment in an English picture. Again the Præraffaellites had been very neglectful in one branch of nature, viz., drawing after the nude. He believed the Præraffaellites had a great dislike to the study of that noblest form of nature, the nude human figure. Now he thought there was a great deal of cant in that matter, and that if they were to turn their attention to that branch of nature, and do in it as much, and in as reverential and proper a spirit as in other matters, they would do well.

The Rev. George Williams coincided with what Mr. Scott had said about the absence of atmospheric effects in Palestine, and which accounted for their non-appearance in the last great work of Mr. Holman Hunt. After complimenting the view of Jerusalem by the late Mr. Seddon, he said he thought the Præraffaellite painters deserved well of the Gothicists, and that they should congratule themselves and art on the effect produced by the operations of Præraffaellites. Præraffaellites might have committed mistakes, but he thought they owed them a very large debt of gratitude; and there was a great deal which they might do in the decoration of works of eminent architects now engaged in the production of structures, not only in this country, but even at the antipodes.

Mr. Street begged to correct Mr. Scott as to the abandonment of the study of the nude by the Præraffaellites.

Mr. Seddon mentioned other instances besides the Union Rooms, Oxford, in which certain Præraffaellite artists had attempted works on a large scale; in particular, a reredos by Mr. Jones, for S. Paul's, Brighton; and an altar-piece for Llandaff Cathedral, by Mr. Rossetti.

The President in reply congratulated the meeting both upon the great good-humour shown and upon the substantial agreement of the speakers. He ventured to say this, for there was no one however laudatory who did not acknowledge more or less that the school had fallen into peculiarities, and as soon as they were given up Præraffaellitism would come to a natural end, and its professors would simply be able and careful painters. There were certain broad distinctions of form and construction which distinguished Gothic and Classical architecture, but there was no such tangible demarcation between Præraffaellite and other painting. Personally he spoke without favour or prejudice, as the only Præraffaellite artist he had ever been acquainted with was the late Mr. Seddon, of whom none could speak without regret and admiration. In conclusion he drew the attention of the meeting to some ivories and to a handsome jewelled cross, which were sent to the meeting by Mr. Gambier Parry; to a frontal, worked by the Ladies' Ecclesiastical Embroidery Society, for Little Cawthorpe Church, Lincolnshire; and to numerous specimens of church plate, exhibited by Mr. John Keith, silversmith to the Society, 41, Westmorland Place, City Road.

THE LATE AUGUSTUS WELBY PUGIN.

A movement is on foot for raising a monument to the memory of the late Augustus Welby Pugin; and we are glad to hear that it is taking so practicable and useful a form, as to enable many to join in it who would perhaps, not feel bound to help, if the object were only a stained-glass window or a statue to the memory of one, who though singularly gifted, enthusiastic, and energetic, nevertheless failed to leave behind him any work, which can fairly be pronounced a great work of Art for all time. Pugin died young; but the deed for which he really deserves credit is the stimulus his writings,—even more than his buildings,—gave to the revived study of mediæval architecture, sculpture, and painting. It is right, therefore, that any scheme, the object of which is to preserve and do honour to his memory before men, should take a form such as that which the proposition now assumes,—namely, a Travelling Studentship (to which it is proposed to add a Medal), generally analogous to those of the Royal Academy, but tenable only for travels in the United Kingdom, and for drawing its mediæval antiquities. This is the thing above all others to which young students of architecture ought to give their attention, and, as far as we are able to judge from architectural exhibitions, just at the point to which they seldom do attend. If there were a more earnest study of ancient architecture, we should have fewer blunders and fewer absurdities than now; and unless men study the old examples when they are young, it is notorious that they never do so at all. Such a memorial as that proposed, Pugin himself, we cannot doubt, would most approve; for he was ever earnest and willing to assist others in life, and could not but rejoice that his memory should also be serviceable to men, in aiding the study he most delighted in. It is one, moreover, that may be joined in by all lovers of our ancient architecture, however diverse may be the degrees of their estimates of the works of Pugin himself.

The Committee consists of upwards of seventy noblemen and gentlemen, the Chairman being Mr. Beresford-Hope, who is also joint Treasurer with Mr. G. G. Scott. The Honorary Secretaries are Mr. Joseph Clarke, of 13, Stratford-place, and Mr. Talbot Bury, of 48, Welbeck-street, London.

The following words of Pugin himself, at page 20 of his *Apology for the Revival of Christian Architecture in England*, confirm in a peculiar manner the original opinion of the Committee that the form of memorial proposed is the most appropriate:—

"God grant me the means and I would soon place architectural studies on such a footing that the glory of these latter days should be even greater than that of the former. I would also have travelling students, but I would circumscribe their limits: Durham the destination of some; Lincolnshire's steepled fens for others; Northampton's spires, and Yorkshire's venerable piles; Suffolk and Norfolk's coasts; Oxford, Devonshire, and Warwick, each county should be indeed a school—for each is a school—where those who run may read, and where volumes of ancient art lie open for all inquirers."

THE NEW ROYAL MAIL VANS.—As those excellently and appropriately-designed vehicles—forming a marked contrast to the cumbersome "old times" vans hitherto in use—are the subject for much admiring comment in this city at present, *we* must also congratulate the builders, the Messrs. Anthony and Henry O'Neill, of the North Strand, on the manner in which they have turned them out, which is certainly a credit to our manufacture in that branch.

THE OPERA.—On the 10th instant a galaxy of musical talent, comprising the well-known artistes, Grisi, Viardot, Orvil, Sedlatzek, Rita, and Gassier; Mario, Luise, Graziani, Fellar, Kinni, Chierci, Forsi, and Ciampi, will appear at the "Royal" for a short series of Italian operas. The lessee reminds the public that this will be the *only* engagement of the kind this season.

GLASS, AND ITS USES.

On the evening of the 20th nlt., a highly-interesting lecture was delivered in the Rotundo by Mr. Frederick S. Barff, M.A., Cambridge (who is favourably known in the artistic world for his church decorations), of which the following is the substance:—

The lecturer, after observing that however simple the subject of his discourse might appear, it had much more in it than was apparent, proceeded to give the various derivations from which the word "glass" is supposed to come. He next brought under the notice of the audience the antiquity of glass. The Egyptians were the first known manufacturers of glass. Small figures of Egyptian deities, composed of vitrified material—turquoise coloured—were found in unrotting mummies now in the royal museums of France and England. And there was evidence existing to show that the Egyptians were acquainted with both the component parts of glass and the method of working it in several ways. It was asserted that the Israelites discovered how to make glass in the wilderness; others held that it was the Phœnicians who discovered the process through the action of their fires on the sands of the river Belas, near which they had encamped after shipwreck. In iron manufacture the substance of glass was necessarily produced, and if Tubal Cain, who was the first artificer in iron, smelted the substance, he certainly must have made glass. In the burned city of Nineveh, Mr. Layard, who conducted the excavations there, found lenses of glass such as are used in telescopes and opera glasses. The celebrated Portland vase, of date 230 years before Christ, was composed of blue glass transparent, and in the city of Thebes, of antiquity of 3,000 years ago, glass articles were used. In the Christian era St. Jerome mentions the use of glass, and in the eleventh century the article was in general use for domestic purposes in these countries. Glass was, however, before that period known and used in France, where the patents for its manufacture were given only to noblemen and gentry, whose sons actually worked as artificers of glass. About this time Venice took a decided lead in the manufacture of the article, excelling all other countries in the value of the material, the beauty of the colour, and perfection of translucency. The first mirrors were made of Venetian glass. In 1665 plate glass was manufactured at Tour le Ville, near Cherbourg, under the patronage of the Minister Colbert, who invited to France Venetian artificers. Flint glass was introduced into England in 1557. From that time it had gradually improved in quality, and at the present time British flint glass was equal to any manufactured in the world. The purest and best glass was made out of white sand. In the North of Ireland were two mountains supplying white sand of unequalled quality for glass, but he regretted to say that the owners of these mountains were not yet liberal enough to allow the sand to be carted away by some enterprising parties who would manufacture it into Irish glass of unrivalled superiority. The lecturer described the various kinds of plain and coloured glass now in general use, and the different processes of manufacture, dwelling specially upon the manufacture of glass invented and carried out by Mr. Hartly, of Sunderland. He then proceeded with the second part of his discourse, which treated of glass painting. There were three styles of this art, the first commencing in the year 1230, the second in 1380, and the third in 1530. The first style was the Mosaic, the second the enamel Mosaic, and the third of enamel altogether. There really was no mystery about the art of painting glass, however certain parties might try to make people believe there was. The colour might be put on glass as any other substance, and when burned in, or fused, the work was permanent. The great object of painting glass for churches was to preserve harmony of colouring and secure the dim religious light. This pleasing and solemn effect was admirably produced by the artists in the first period of the art, in the second not so well, and in the third, least successfully of all, owing to the introduction of figures. Painting on glass and painting on walls were entirely different things; and he regretted that the distinction was not as well observed as it ought to be in the present period of the art of glass staining. There should be no attempt at perspective in glass painting for churches; every figure and ornament should be set in plain and level, as it were, taking care that the harmony of the colours should be preserved. This was the practice of our forefathers, and it ought to be followed now. Ireland possessed few remains of ancient stained glass, nearly all were destroyed, as in England, by Cromwell. Beautiful specimens, however, were in the cathedrals of Canterbury and York Minster—the colours rich and flowing, and in perfect harmony, producing a magnificent effect. The lecturer criticised with some severity the present style of art followed in glass painting for churches, particularly in reference to the attempts at perspective, and the introduction and drawing of figures. He held that there was no reason why we should follow the grotesque drawing and drapery of the figures in the ancient style, and that it would be well that artists would depict things as they really are. The lecturer gave a brief sketch of opaque painted glass, mentioning the fine specimens that existed in the roofs of St. Peter's church at Rome, and St. Mark's at Venice. He concluded by expressing a hope that Ireland, which possessed in such abundance the materials for the manufacture of the best glass, would yet be distinguished for the produce of that article, and that Irish artists might be found to adorn churches with stained windows, exemplifying the true principles of art, and consequently becoming worthy of the religious purposes to which they would be applied.

OPENING OF THE STREET TRAMWAYS AT BIRKENHEAD.

On Thursday, the 30th ult., the new street railway, connecting Woodside Ferry with the Park at Birkenhead, was opened, and the event inaugurated by a magnificent banquet, at which some 400 persons were present. Mr. George Francis Train, the proprietor and patentee, occupied the chair, and amongst the company were, Mr. John Laird, the eminent ship-builder; Mr. William Dargan, Aldermen Kinahan and Mackey, Mr. Frith, C.E., and Mr. Bower, C.E., from Dublin. The English press was represented by numerous gentlemen, and the Irish likewise by Dr. Maunsell, of the *Evening Mail;* Mr. J. J. Lyons, proprietor and editor of the Dublin Builder; some gentlemen from the *Freeman*, *Morning News*, &c. The Editor of the *Melbourne Argus* also attended, and acknowledged briefly, but suitably, the toast of "the Press." During a period of six hours—viz., from 2 p.m. to 8 p.m.—a very animated discussion upon certain interesting and substantial topics, in which "the glorious vintage of champagne" occupied not the least important position, took place, and a few excellent speeches were delivered, amongst which the truly brilliant oration of Mr. Train shone refulgent. Some 5,000 passengers travelled in the cars over the route, and the greatest enthusiasm prevailed. During the short period of 60 days this road, about 2 miles in length, has been completed, and the cars are commodiously and suitably constructed. We shall revert to the details of the principle fully in next number.

CHARLESTOWN CHURCH, MAYO.

A new church has sprung up with a new town, entitled Charlestown, in a wild part of the county of Mayo, thanks to the energy and liberality of Charles Strickland, Esq., of Lough Glyn; and recently passing through this locality we were not a little astonished to find an edifice of such correct ecclesiastical character in so remote a district. The building is a spacious one, capable of accommodating a very large congregation, and is planned on the usual arrangement of nave, aisles, chancel, sacristy, and porch. Its total internal length is 103 feet by a width of 53 feet. The nave is divided from the aisles by arcades of arches, five on either hand carried on simple chamfered masses of masonry, with a square base in front, such as we find in ancient examples of Irish ecclesiastical architecture, *e.g.*, the old cathedral at Limerick. A lofty arch opens into the chancel, which has an eastern window of four lights, with simple "plate tracery." The clerestory is composed of cinque foiled circles, and the aisles are lit by coupled lights, all of the simplest description. A triplet of lancets under an enclosing arch forms the composition of the western gable, which is crowned by a bell gable—a prominent object for many miles. The chancel window is filled with stained glass representing the Blessed Virgin, St. Patrick, St. Bridget, and St. Charles Borromeo, the patron saint of the Church. The total cost of the building was under £2,000, the work having been constructed in the most solid and substantial manner. The architects were Messrs. Hadfield and Goldie, of Sheffield and Westminster; the builder Mr. Wm. Doolin. We also understand an identical structure has been built at some few miles distance in same county.

Ardgillan Castle, the residence of Colonel Taylor, M.P., has been lighted with gas by Messrs. Edmundson of this city.

The *Art Journal* directs attention to the frescoes of the Houses of Parliament, and says, that some of those beautiful works are completely destroyed, and *all* partially injured, their total destruction being only a matter of time.

An organ has been constructed at Vienna for the Sultan, which is the great wonder of the day. It cost fourteen thousand florins, and is a complete orchestra of fifty musicians, equal to the same in power and expression.

It appears from the account of the police valuator, handed in on the 1st August, that 198 new houses have been occupied for the first time since 1st January last in the town of Belfast.

The cornice of the Turkish baths, now being erected in Donegal-street, Belfast, fell last week, fortunately in the absence of the workmen, carrying with it the scaffolding.

CEMENT AS A SUBSTITUTE FOR STONE.

The "days of yore" were excellent in many ways; each age has its beauties and imperfections, and certainly we may enumerate amongst the former the strength of will and perseverance displayed in their still strong and permanent structures, though they may have used a superabundance of material. They intended to build for posterity, and they did so. The artist, poet, sculptor—all worshipped at the same shrine, and emulated each other in the production of works of art, which may be fitting ornaments to the buildings containing the altar of their religion. On the other hand, the domestic dwellings were lamentably deficient. In a state of vassallage, the lower classes were cared for, housed, clothed, fed; and the wealthier citizens had not arrived at that position wherein necessity calls loudly for new ideas and rules as regards health, convenience, and economy. The rude tenement, besides, had more charm for their hardy natures than ours, built to satisfy our commercial requirements. On those buildings, however, to which they attached the greatest importance they lavished money and time, and our modern architects are proud to copy them. Their style is copied by us, many of their ideas have been improved upon, but the excellence and finish of their execution has never yet been attained by us. And as regards their substantiality, we are warned to notice one evil which has been rapidly invading our architectural efforts—the extensive use of cement, and even now it is a matter of investigation how much further its use may be carried for *heavy* projections, with a lining as a substitute for brickwork. We daily see columns under porticoes made up of bad brickwork and plastered over with cement, Carton-pierre used immoderately in the way of decoration, whole house-fronts nothing but cement, which, with a hot sun and bad work behind, will tell fearful tales in a very short space of time, and this is the opinion of architects who use it. Our noblest mansions are now generally reared in this flimsy manner, with less expense, of course, but what will a short-lived economy be worth when they will have been fairly tried by rain, frost, heat, &c., and those peculiarities of climate to which we are subject? A dread of the *striking* qualities of masons (which, we believe, first suggested the use of cement at all for facing houses) may act upon the prejudices in its favour; but we prefer the brick, for what after all looks so well as good, level, nicely-pointed brickwork, with a polychromatic arrangement, no staining, no colouring, but a natural colour from the kiln.

This is an age of card-houses, wicker-castles, and penny-peep-show-palaces! We are gradually lessening our building expenses till we shall perhaps arrive at a parallel consummation with that attained by the individual who trained his horse to live upon nothing, and was disappointed one morning to find him dead! We shall learn to cut it so fine as to find our houses tumbling about our ears. We should be sorry also to say that building had become a mere trick of trade, and a specification, which was at one time a mere code of instruction, is now a sort of man-trap, constructed on the most scientific principle, and forced by existing circumstances! Since then our interiors are flimsy, we cannot expect much else in our exteriors, and this system altogether has created a class of builders who live by the flaws of specifications, and substitution of bad for good material. This may be digressive, but having a connection with the general principle which we condemn, we could not avoid an allusion.

To return to cement-facing. Is it because we are used to stone columns, for instance, that we must use brick and cement? Why should we not have brick? In rows of houses the moulded bricks, pointing, &c., could be done at as little expense as left rough and cemented. Columns of red brick ranged here and there with blue or yellow, with stone or iron caps and bases, would not interfere with the orders, as they are of proportion, not colour. Pilasters, plinths, cornices, parapets, look well in brick, which we would strongly advocate in preference to cement—the sheeps' clothing of modernized architecture. Rome, in all her greatness, considered her pottery and tile-making not the least of her achievements; we should be proud of our brickwork, and never strive to deface it by a mad imitation of stone, and which (excepting it be of the very best description) is bad indeed.

We have thus inconsistencies of a remarkable nature. On the one hand, the society of antiquaries stripping plaster off our old church walls; on the other, architects running up edifices, smothering them in cement and Carton-pierre, and whilst they declaim against all which may savour of the *untruthful* in architecture, erect it daily as evidence of their inconsistency. If there is to be an acknowledged and universal principle, let it be carried out, for they who write "Essays on Taste" command our admiration, which is received in *word* and denied in *deed*, and whilst disciples avoid actual inconsistencies pointed out to them, commit others twice as extravagant.

As regards the use of cement generally, it would no doubt be found enormously expensive to erect mansions, warehouses, and public buildings, facing them entirely with stone: but the use of brickwork, with stone used discriminately here and there, would look far better than cement, and cost no more, and be far more likely to preserve for us a pretension to national style. R.

ST. PATRICK'S CATHEDRAL.

(COMMUNICATED.*)

For many years past the ruinous condition of the venerable Cathedral Church of St. Patrick, in this city, has been a subject of continually increasing anxiety and regret. Originally well built, though not with the best materials, it has yielded very slowly to the destructive influences of time and climate; nor could it be doubted that, if ordinary attention had been paid to the necessary repairs, it might yet for many centuries be preserved as a monument at once of architectural skill and national piety. The Dean and Chapter have very inadequate resources for this purpose, and it is, perhaps, fortunate that they did not possess larger funds applicable to building and repairs, for to this circumstance we are indebted for the preservation of much that is really antique. Had the Economy Fund been large, it would, no doubt, have been expended liberally; but if we may judge from what has been hitherto done in that way, the result would only have been the irreparable disfigurement of the church with carpenter's Gothic and other tasteless incongruities. The deficiency of funds, if it has acted injuriously in one direction, has had a conservative influence in another, and has obviated many difficulties in the task of a successful restoration. It is now well known that in our respected fellow-citizen, Benjamin Lee Guinness, the church has found a benefactor, whose munificence has no parallel in this country since the age in which its cathedrals were built, when the animating sentiment alike of princes and people was to give the Lord the honor due unto His name—worship the Lord with holy worship. But it should be equally well known that the church will be still more indebted to Mr. Guinness for the good judgment and correct taste with which he directs the expenditure of his £20,000 on the works of reparation. His principle is to replace whatever is decayed, adhering exactly to the ancient patterns, and making no other alteration than the substitution of a better material. The plan is to restore, but not to innovate. In all previous repairs this principle was neglected, except only in the single instance of one buttress and pinnacle on the north side of the choir, which was truly restored by the present Dean soon after his appointment, but with the judicious alteration of using a good durable limestone in place of the soft sandstone previously employed, which, from its readily yielding to the action of the atmosphere and rain, is quite unfit for the exterior of a building. Mr. Guinness is ably seconded by his builders, the Messrs. Murphy, of Amiens-street, who have engaged in the work with much diligence and constructive skill as leaves nothing to be desired. The progress already made, within the brief period of about five months, is sufficient to enable us to estimate the general character of this great undertaking; but previous to giving any details, it is necessary to advert to the early history and recent condition of the church. Archbishop Usher says that it is uncertain when this Church of St. Patrick was first founded, but he states that it was enlarged by King John, and was first made præbendal by Archbishop Comyn, in the year 1191, with the approval of Pope Celestine III., and that by his successor in the see of Dublin, Henry de Loundres, it was raised to be a cathedral, after the model of the Church of Salisbury. The foundation of the present church is, however, distinctly ascribed by historians to Archbishop Comyn, and was consecrated in the year 1191. The ground plan, like that of most cathedrals, was cruciform, the church, when completed, consisting of nave, choir, and transepts, all these parts having aisles. In or about the year 1270 an eastern chapel was added, and dedicated to the Blessed Virgin Mary, or, according to some accounts, to St. Stephen; and the choir aisles were extended eastward, so as to partly include this chapel between them. About the year 1370 the great square tower was erected at the north-western extremity of the nave, where it stands engaged in the exterior wall of the north aisle. On this tower a granite spire was erected in the year 1750. The prevailing style of the entire church was the simplest and most severe of the Gothic, or, as it is now the fashion to say, the early English; but some diversity of style was gradually introduced, if not during the progress of the original building, at least in the extensive repairs of subsequent centuries. To the latter part of the fourteenth century we may refer the window with flowing tracery at the west end of the north aisle of the nave, and to the same period probably belong also the four western arches on that side, which, as well as the clerestory windows for the same extent, exhibit sufficient differences from the remainder of the body of the church to mark a later period. The simple lancet-lights of the aisles in both choir and nave were at same time replaced by larger mullioned windows belonging to the decorated style; one only of the original windows remaining in the north aisle of the nave, next the tower, where it may still be observed; but until some alterations had been made a few years ago, the arches of the original opes could be seen plainly in the exterior masonry of the aisle walls. The great west window in the perpendicular style is obviously an interpolation of even later date. The clerestory of the choir was supported on the outside by flying buttresses—four on the north and four on the south side. We cannot determine whether these were part of the original plan, or additions as ornamental as they were useful, made at a later period to resist the outward pressure of the stone vaulting of the lofty choir. The shafts of the pinnacles were square in the horizontal section, were decorated with tracery, and surmounted with caps which were either conical or octagonal pyramids; but being constructed of a soft stone had yielded so much to the weather that their true figure cannot now be precisely ascertained; but there is no doubt whatever as to the shafts and ornamentation of those pinnacles. There were no pinnacles on any other portion of the building, and it is to be regretted that one flying buttress has been completely removed on the north side, and two others at the north-eastern and south-eastern angles rebuilt with their pinnacle shafts of an octagonal form, and over-capped so much that when viewed in profile against the clear sky they resemble nothing so much as a mould candle with an extinguisher. The north transept, which has long been used as the parish church of St. Nicholas, was permitted to become a ruin towards the end of the last century, and was completely demolished about forty years ago. It has been rebuilt with better stone, but with very little attention to the style of the cathedral, and is still used as a parish church. The eastern chapel, which for many years had been used by a congregation of French refugees who conformed to the Established Church, and afterwards as a chapter house, was entirely taken down about ten years ago, although quite susceptible of repair, and has been rebuilt on the original, but with this fault among many others, that the soft sandstone imported from Caen has been again used in most exposed situations—in quoins, angles, and weathering of buttresses, where it is already going to decay and disfigured by cryptogamic vegetation. The south transept and south wall of the nave had long been in a precarious or dangerous condition. Either at the beginning of the eighteenth or the close of the seventeenth century, two clumsy but effective flying buttresses had been erected for their support. These will be remembered as one on the south side of the nave, the other on the west side of the south transept. Both were surrounded by stone balls, such as usually decorate gate piers, and were incongruous though useful. Their utility would not have been less had they been modelled after those of the choir. But the stability of the nave had been seriously impaired by cutting into the pillars for the insertion of monuments, most of which were in the worst taste, and all inappropriate to the style. A further injury was done in Archbishop Magee's time by the erection of two huge galleries in the nave, by which, when occupied, a great additional weight was thrown on the piers already weakened. The triforium of the nave was sacrificed to those hideous constructions. The equilibrium was so disturbed by those conjoined causes that about fourteen or fifteen years ago an attempt was made to strengthen the nave piers by removing their exterior and replacing it by a thin casing of cut stone. This gave but little, if any, additional support, and it was then found necessary to prop up two arches by strong timber frames and centering. In this state the church fortunately attracted the attention of Mr. Guinness. He saw at once that but one remedy could be applied. The ruinous portions, extensive as they were, should be entirely removed, and replaced by a new structure, retaining the form and appearance of the original, but far surpassing it in strength of construction and quality of material. He has engaged simultaneously in several distinct parts of his great enterprise, of which we may with truth say that it was with him a labour of love. The south wall of the nave has been taken down, after the monuments had been first carefully removed for re-erection in more suitable positions. The house of God should not resemble a sculptor's gallery or a museum of curious objects. The rebuilding has already commenced in the nave. Three of the pillars, which are to support the great arches and their superstructure, have reached their full height. They are built from the foundation on the same site as their predecessors held, but instead of rubble masonry they are constructed of solid granite of Cyclopean strength and proportions. Exterior to this core, which is 3 feet 10 inches in diameter, will be a casing of Caen stone, in which the engaged columns ("the shafted stalks," as Scott calls them) are formed. Of this exterior casing there are portions already in position; and from even these specimens we can judge how fine will be the effect of the entire when completed. It is not too much to say that it could not be surpassed by Pugin in his best efforts. The draining of the church, which hitherto has been most ineffectually attempted, although the vicinity of a running stream offered great facilities, has received due attention, and may now be considered as accomplished. While these works were proceeding in the nave the reparation of the exterior of the choir has also been commenced. Every one that has viewed the church from the south must have remarked the crumbling jambs and arch mouldings of the clerestory windows, and the dangerously ruinous state of the pinnacles of the original flying buttresses. These pinnacles are now nearly down to the spring of the arches; they have been strengthened from below, and will be exactly rebuilt of the former pattern. The two most easterly of the choir clerestory windows on the south side have had their decaying stone work removed, and replaced with exactly similar jambs and mouldings cut in the best Irish limestone. The fidelity of the restoration can be proved by a comparison while there is opportunity with the adjoining windows not yet touched. The works throughout will be equally honest, an honor to the donor, and all under his direction. But we would wish to see photography employed to preserve accurately the form of every part that is to be removed. The greater part of the south transept, both within and on the exterior, demands this precaution. Its eastern wall is on the interior aspect very beautiful, and has some ornamental features which distinguish it from the western. The western extremity of the south aisle of the nave is to the extent of two arches occupied by an ancient crypt of great age, perhaps a remnant of the earlier church, possibly the original seat of the University of Dublin in the early part of the fourteenth century, and certainly that of the school in which Archbishop Usher, who was born and reared in Nicholas-street, received his early education. We hope that it may be decided to preserve this interesting remnant of antiquity, which is capable of being rendered a very appropriate church porch. The only reason we have heard for proposing its removal is, that it prevents the formation of a large decorated window corresponding to that of the opposite aisle; but that window of the north aisle, though undoubtedly beautiful, is itself an innovation, and it is by no means necessary that there should be an exact symmetry of the two opposite sides. If there were such a principle in the Gothic, it would follow that another tower should be erected at the south-western angle to match the present steeple. Cathedrals such as Exeter, which have two towers, usually have them somewhat different in style and finish of their details. To the completion of St. Patrick's stained-glass windows would be essential, but this would entail an amount of expense which should not be allowed to fall on Mr. Guinness. In the eastern window there was an appropriate ornament, the Star of the Order of St. Patrick, which, in some recent attempts at improvement, was swept away. Should not something better have been first provided? In the same spirit of innovation was destroyed the altar-piece, a fine picture of the sun rising, in allusion either to the "Dayspring from on high," or to our Lord, "The Sun of Righteousness." For this a plain glass sash window, or glazed screen, has been substituted. With the better system of improvement that is now in progress, we may hope that all these incongruities will disappear, and that the state of the church may in future be such that the harassed student who attends Divine Service on the Lord's Day, may be able to sympathize with the great English poet, when in his better days he sung—

---

* This article is *quoted* from a local contemporary.

> "But let my due feet never fail
> To walk the studious cloysters pale,
> And love the high embowed roof,
> With antique pillars massy proof,
> And storied windows richly dight,
> Casting a dim religious light.
> There let the pealing organ blow,
> To the full-voiced quire below,
> In service high, and anthems clear,
> As may with sweetness, through mine ear,
> Dissolve me into extasies,
> And bring all Heaven before mine eyes."

If this should ever be realized in our time-worn and ruinous cathedral, it will be owing to the princely generosity and correct taste of Benjamin Lee Guinness.

Fortifications of Waterford Harbour.--The additions and alterations at Duncannon Fort are now completed. Capt. Synge, commanding Royal Engineers at the Curragh Camp, together with Lieutenant Price, R.E., from Kilkenny, inspected the works, and were much pleased at the manner in which they were carried out by Mr. Abraham Stephens. The sea face of the fort is now prepared for mounting nine 68-pounder Armstrong guns, on traversing platforms, capable of throwing shot and shell 6 miles to the entrance of the harbour. There has also been erected two extra magazines and five shell rooms for the storage of shot and shell for the use of those large guns, together with four bangriette for riflemen.

ASSERTED DISCOVERY OF A PAINTING BY CORREGGIO.

THOSE of our readers who have visited that portion of the national collection of pictures which comprises the works of foreign schools, and is exhibited in Trafalgar-square, London, need not be reminded that among the most brilliant works of that superb collection are certain pictures by Antonio Allegri, better known as Corregio, from the small Italian town which gave him birth in 1493, and witnessed his early death in 1534. He is supposed to have been instructed in art by Antonio Bartolotti, a painter of the same place, and by 1219 had become a master of established reputation at Parma.

"Corregio's frescoes, and even some of his oil pictures, are remarkable for violent but skilful foreshortenings. His proverbial *grace*, apparent not only in his undulating forms and soft transitions, but in the action and expression of his figures, is a distinctive characteristic of his works; and he is still unrivalled in a certain harmony which results from delicate gradations of light and shade.

"The pictures of Corregio were so exclusively conspicuous for these qualities before the rise of the modern school of Bologna, that the first sight of some of his works forced Annibale Carracci, in a letter to his cousin Lodovico, to declare that in comparison with them the St. Cecilia of Raphael appeared to be wooden."

Now among the most exquisite examples of the master there are two which were acquired through the medium of an Irish nobleman, and of which we shall transcribe the official statements, viz:—

"No. 10. Mercury instructing Cupid in the presence of Venus. Mercury dressed in his winged cap (Petasus) and sandals (Talaria), is seated on the ground, and is endeavouring to teach Cupid his letters, of which, according to a Greek myth, he was the inventor. The little god, standing by his side, appears to be paying due attention to his lesson. Venus, here represented as winged, has taken temporary charge of Cupid's bow, which she holds in her left hand, and appears to be entertained with the novel spectacle. The back-ground of dark foliage contrasts finely with the well-rounded nude of the figures. Entire figures nearly of the natural size.

"Engraved in a large scale by Arnold de Jode, in 1667, and in small in 1786, by Le Villain, for the *Galerie du Palais Royal*, in which there was a duplicate of this composition. On canvas, 5 feet 1 inch high by 3 feet wide.

"This picture, one of Correggio's masterpieces, was formerly in the possession of Charles I., who purchased it of the Duke of Mantua with the rest of that prince's collection in 1730. It was bought, after the dispersion of the king's effects (it brought £800 at the sale), by the Duke of Alva; it was subsequently the property of the Prince of Peace, in whose collection it was at the time of the occupation of Madrid by the French, when in 1808 it fell into the possession of Murat, afterwards King of Naples, and it was thus, after a lapse of two centuries, restored to Italy. Its next possessor was the Marquis of Londonderry, who obtained it, together with the 'Ecce Homo,' No. 15 in this collection, of the ex-Queen of Naples, at Vienna, and both pictures were purchased from the Marquis of Londonderry, in 1834, for the National gallery.

"No. 15. Christ presented by Pilate to the people, called the 'Ecce Homo.' 'Then came Jesus forth, wearing the crown of thorns, and the purple robe. And *Pilate* saith unto them, Behold the man!'—John xix. 5.

"The greater part of the picture is occupied by the figure of our Saviour, behind whom to the left is Pilate, pointing with his right hand to Christ, and uttering the words which constitute the title of the subject. On the right is seen the head of a Roman soldier, and in the fore-ground to the left the Virgin Mary is represented in a swoon, supported in the arms of St. John. Half length figures of the natural size.

"Engraved in 1587 by Agostino Carracci, of which print there are several copies; more recently by P. Bettelini, and by G. T. Doo, R.A.; and in small, in Jones's National Gallery. On wood, 3 feet 2¼ inches high by 2 feet 7¼ inches wide.

"This picture, formerly in the possession of the Counts Prati, of Parma, was subsequently long in the Colonna Palace in Rome, and it was, according to Ramdohr, the best picture by Correggio in that city (in 1784). It is noticed also by Mengs, who supposed it to be one of the painter's earlier works. It was purchased of the Colonna family by Sir Simon Clarke, who, being unable to remove it from Italy, sold it to Murat, then King of Naples, and, as already mentioned, it was purchased, with No. 10, from the Marquis of Londonderry, in 1834."

There is undisputed evidence that the painter copied or reproduced his works, as in the case of "Christ's Agony in the Garden," one representation of which subject is in the national collection, and another in that of the Duke of Wellington's.

That there should be two pictures of the "Ecce Homo," therefore, is brought within the scope of probability, and we thus arrive at the point which has created some sensation among the *cognoscenti* of London.

It appears that about eight or ten weeks since a work was left for the inspection of a dealer, and after some washing and scraping was found to have been disguised by a super-coating of paint. This was judiciously removed, the picture relined, and being placed in a boldly-carved and newly-gilt frame, under a sheet of plate glass, has been made the subject of an exhibition.

It is not a copy of the *facsimile* class, but one in which considerable latitude has been assumed by the producer; and this is a circumstance undoubtedly favourable to the assumption that it is the work of Correggio's hand. Christina, Queen of Sweden, is known to have possessed several of his works, and the possibility of such a source is not forgotten.

As to the value of such a work, if proved to be genuine, some clue is suggested by the price (£11,500) paid to Lord Londonderry for the two pictures obtained of him. Everything, of course, depends on the authenticity of the work; but whether that be established or not, we are led to think the precedence in breadth, grace, and delicacy, those finer qualities which constituted the "*Correggiocity of Correggio*," will remain with the national picture.

BALLAGHADEREEN CATHEDRAL, CO. MAYO.

OUR readers will be interested, and probably somewhat surprised to learn that during the last four or five years a large cathedral church of a dignified and strictly ecclesiastical architectural character, has been growing up in this remote locality, out of the line of railways and amidst a wide extent of bogs and comparatively sterile country. The energy of the Roman Catholic Bishop of the diocese of Achonry, seconded by his clergy, and the cordial co-operation of some of the more influential laymen of the neighbourhood, has been the motive power which has produced this important work. The church, which has been built after designs by Messrs. Hadfield and Goldie, architects, consists of the ordinary constituent parts of a parochial church, viz., a nave and aisles, chancel with side aisles forming chapels, and the dependancies of porches, sacristy, and a western tower and spire yet to be erected. The total internal length of the building is 150 feet, its width being 59 feet, with a height from the floor of the nave to the apex of its roof of 67 feet. The style is a simple Gothic, known as "Early English" or "First pointed." A very noble arcade of eight arches on either hand forms the nave, carried on cylindrical shafts, with lofty bases and moulded capitals, the arches and capitals being wrought in white Scotch sand-stone, the bases and shafts in the local blue lime-stone. A chancel arch of lofty proportions, with shafted jambs, and a moulded arch, opens into the chancel, which has a noble eastern window of six lights; smaller arches terminate the aisles, and give access to the chapels which flank the chancel, into which they open by other arches. The roofs are framed in open timbers, the original intention having been to cover or vault them in wood and plaster, but this has been abandoned on the ground of cost. A lofty tower and spire is hereafter to be added at the western extremity of the nave. The high altar for the chancel is in progress of execution in the workshops of Mr. Henry Lane, of Dublin, whose works at Dominick-street Church and other places are so well known to our readers. The altar and tabernacle are to be of Caen stone and Irish marbles,—the tabernacle rising to a considerable height in rich canopy work, crowned by a rich gilt cross, set with crystals. The door will be likewise richly gilt and engraved. The reredos is to rise to a considerable height behind the altar, and will be formed of Caen stone, encausted with enamelled tiles of rich colours. Beyond the high altar no other fittings are as yet in progress—they will be undertaken by degrees. It is expected that the church will be ready for opening next month. Mr. Charles Barker is the clerk of the works. The total cost will be about £5,000.

NEW NATIONAL BANK IN LONDON.—A correspondent enquires, "are we aware that the *National* Banking Company of *Ireland*, comprehending *five-sixths* of shareholders *Irish*, are about expending £30,000 on a new bank at their head quarters in London (where they are compelled to pay a heavy amount annually for exchange of their notes into current coin), and why not expend the sum in Dublin in preference?"

THE NATIONAL TELEGRAPH COMPANY.—This company is now in course of formation for the construction of a system of telegraphs throughout the United Kingdom, from London to the principal towns in England, Edinburgh, Dublin, Cork, and Belfast, &c. The system is to be based on the principle of the penny postage, to convey messages at a low or uniform rate of one shilling, or some equivalent charge irrespective of distance.

THE PROPOSED PAROCHIAL CHURCH OF ST. ANDREW.

Our readers have been already acquainted, through the pages of the Dublin Builder, that the designs by Messrs. Lanyon, Lynn, and Lanyon, Architects, sent in competition for the new church to be erected for St. Andrew's Parish, in lieu of that somewhat recently destroyed by fire, were selected by the committee, and the result must prove most gratifying to that firm, as several very eminent professionals entered the lists. As yet it would appear to a certain extent problematical as to whether the structure so designed will be carried out in its integrity or not,—some say not at all,—however we leave that question to be decided by time, but have seized the earliest opportunity in presenting the public with *one* view (at least for the present, though others are in our engraver's hands) of what must be conceded by all to be a very noble and appropriate architectural work. A few words of description moreover, will prove acceptable. The plan is cruciform, with nave 83 feet long by 29 feet wide, apsidal chancel 41 feet by 28 feet, transepts (each) 25 feet by 33 feet, aisles 22 feet and 17 feet respectively, cloister porch, baptistry at south-west angle 14 feet wide, sacristy (under tower) organ loft, &c., &c. The tower, 80 feet in height, shown in the illustration will be in connection with the northern transept, nearly facing Church-lane, and be seen to its base to a considerable distance down Nassau-street; and the spire with which it is intended to be surmounted will attain an altitude of 175 feet to the vane, forming one of the highest of the few landmarks the city can boast of. For the external features generally the perspective illustration, which is taken from north-east angle, is sufficiently descriptive, but we desire to note specially the cloister porch, which with its two entrance doorways and concomitant parts is excellently and picturesquely handled. The style of architecture is the early decorated of the 14th century. Internally the nave will be 73 feet to the hammer beam, have open timber roof stained and varnished, be separated from aisles by an arcade of four bays, with circular piers and pointed arches, and have clerestory windows over same. At the intersection of the transepts with nave are four great arches—springing from clustered piers,—one of which leads to chancel, which is lighted by 5 two-light windows, as seen on the illustration, and will have a stone groined ceiling. The aisle, stated to be 22 feet in width, will be carried up in A form, terminating in gabled ends, and the other have shed roof from about level of clerestory windows, forming a pleasing variety in the outline. The chancel will be floored with encaustic tiles, and no doubt hereafter the windows will be filled in with stained glass. The materials proposed to be employed throughout are granite for the facing of general structure, and Bath stone for the dressing.

The windows throughout are generally in two bays, except that lighting nave, which has five, the north transept four, and the north aisle three. Groined ceilings are provided for the organ room and vestry.

RE-OPENING OF ST. ANNE'S CHURCH.

As already announced, this parochial church has been undergoing a series of improvements mostly internally, but partly externally, in the reconstruction of the side and organ galleries, the general refitting with pews, the opening of new windows, &c.; but the principal works were chiefly confined to the apsidal chancel, which has been newly railed in and tiled with encaustics; two memorial windows, constructed with Bath stone dressings and filled with stained glass, by Warrington, of London, serving as memorials to Knox, the Reformer, and Mrs. Hemans respectively; a beautiful and elaborately carved pulpit, reading-desk, sedilia, and font being likewise added.

The general works were contracted for by Mr. Hall, of Kevin-street, builder, but the carvings and stone dressings connected with the chancel, together with the pulpit, font, and desk, were designed and executed at the establishment of Messrs. Purdy and Outhwaite, Great Brunswick-street, assisted in the former department, as we learn, by a professional gentleman distinguished for his ability in ecclesiastical art. The church was re-opened on Sunday, the 12th ult.

THE BRICKLAYERS OF DUBLIN.

We experience at all times especial pleasure in chronicling the progressive doings of the artizan classes, but probably during our existence never has the opportunity been so favourably afforded as in the recent laudable step of a most important and generally excellent body, "the Dublin Bricklayers." Induced by higher and more ambitious motives than the mere holding of a weekly meeting for general purposes in a locality with infatuating and demoralizing tendency—as is, unfortunately, habituous with the trades throughout the kingdom—the bricklayers have set their fellow-tradesmen an example worthy of being followed, and soared higher; for by the united contributions of the body, and a few gentlemen connected with the building profession, they have succeeded in securing what others cannot boast of—viz., an important building, combining the advantages of a capacious hall for meetings, lectures, &c., a library, a reading-room, &c., and moreover spare apartments for such select members of the craft as by natural infirmity or by accident are debilitated. For this purpose the Cuffe-street Savings' Bank, of notable memory, was obtained by them on lease, and, with a comparatively trifling expenditure, has been adapted to their purposes, and duly inaugurated. We wish every prosperity to the undertaking, and commend it to the consideration of our readers. Mr. John Nolan is the president.

⁂ The Committee gratefully acknowledge the receipt of the following donations, &c., to the Institute:—

John Nolan, Esq., £5, and £1 first annual subscription.
John Bell, part donation, £1, and £1 annual subscription.
Gilbert Cockburn and Son, £5, and £1 annual subscription.
J. Beardwood, Esq., £5, and £1 annual subscription.
John Rooney, Esq., £1, and £1 annual subscription.
John Farrell, Esq., £1, and £1 annual subscription.
Mr. Drysdale, Bank of Ireland, 5s.
Mr. Byrne, Bank of Ireland, 2s. 6d.
Mr. M'Evatt, Bank of Ireland, 2s. 6d.

The Committee respectfully call the attention of the gentlemen of the Dublin Press, and all other well-wishers of progress and social order, to the generous donations and support cheerfully given by the above distinguished and eminent builders of this city, as it will unmistakably show the estimation in which they hold the men of this community after the lapse of half a century.

James Flood, Chairman.
Christopher Tutty, Secretary.

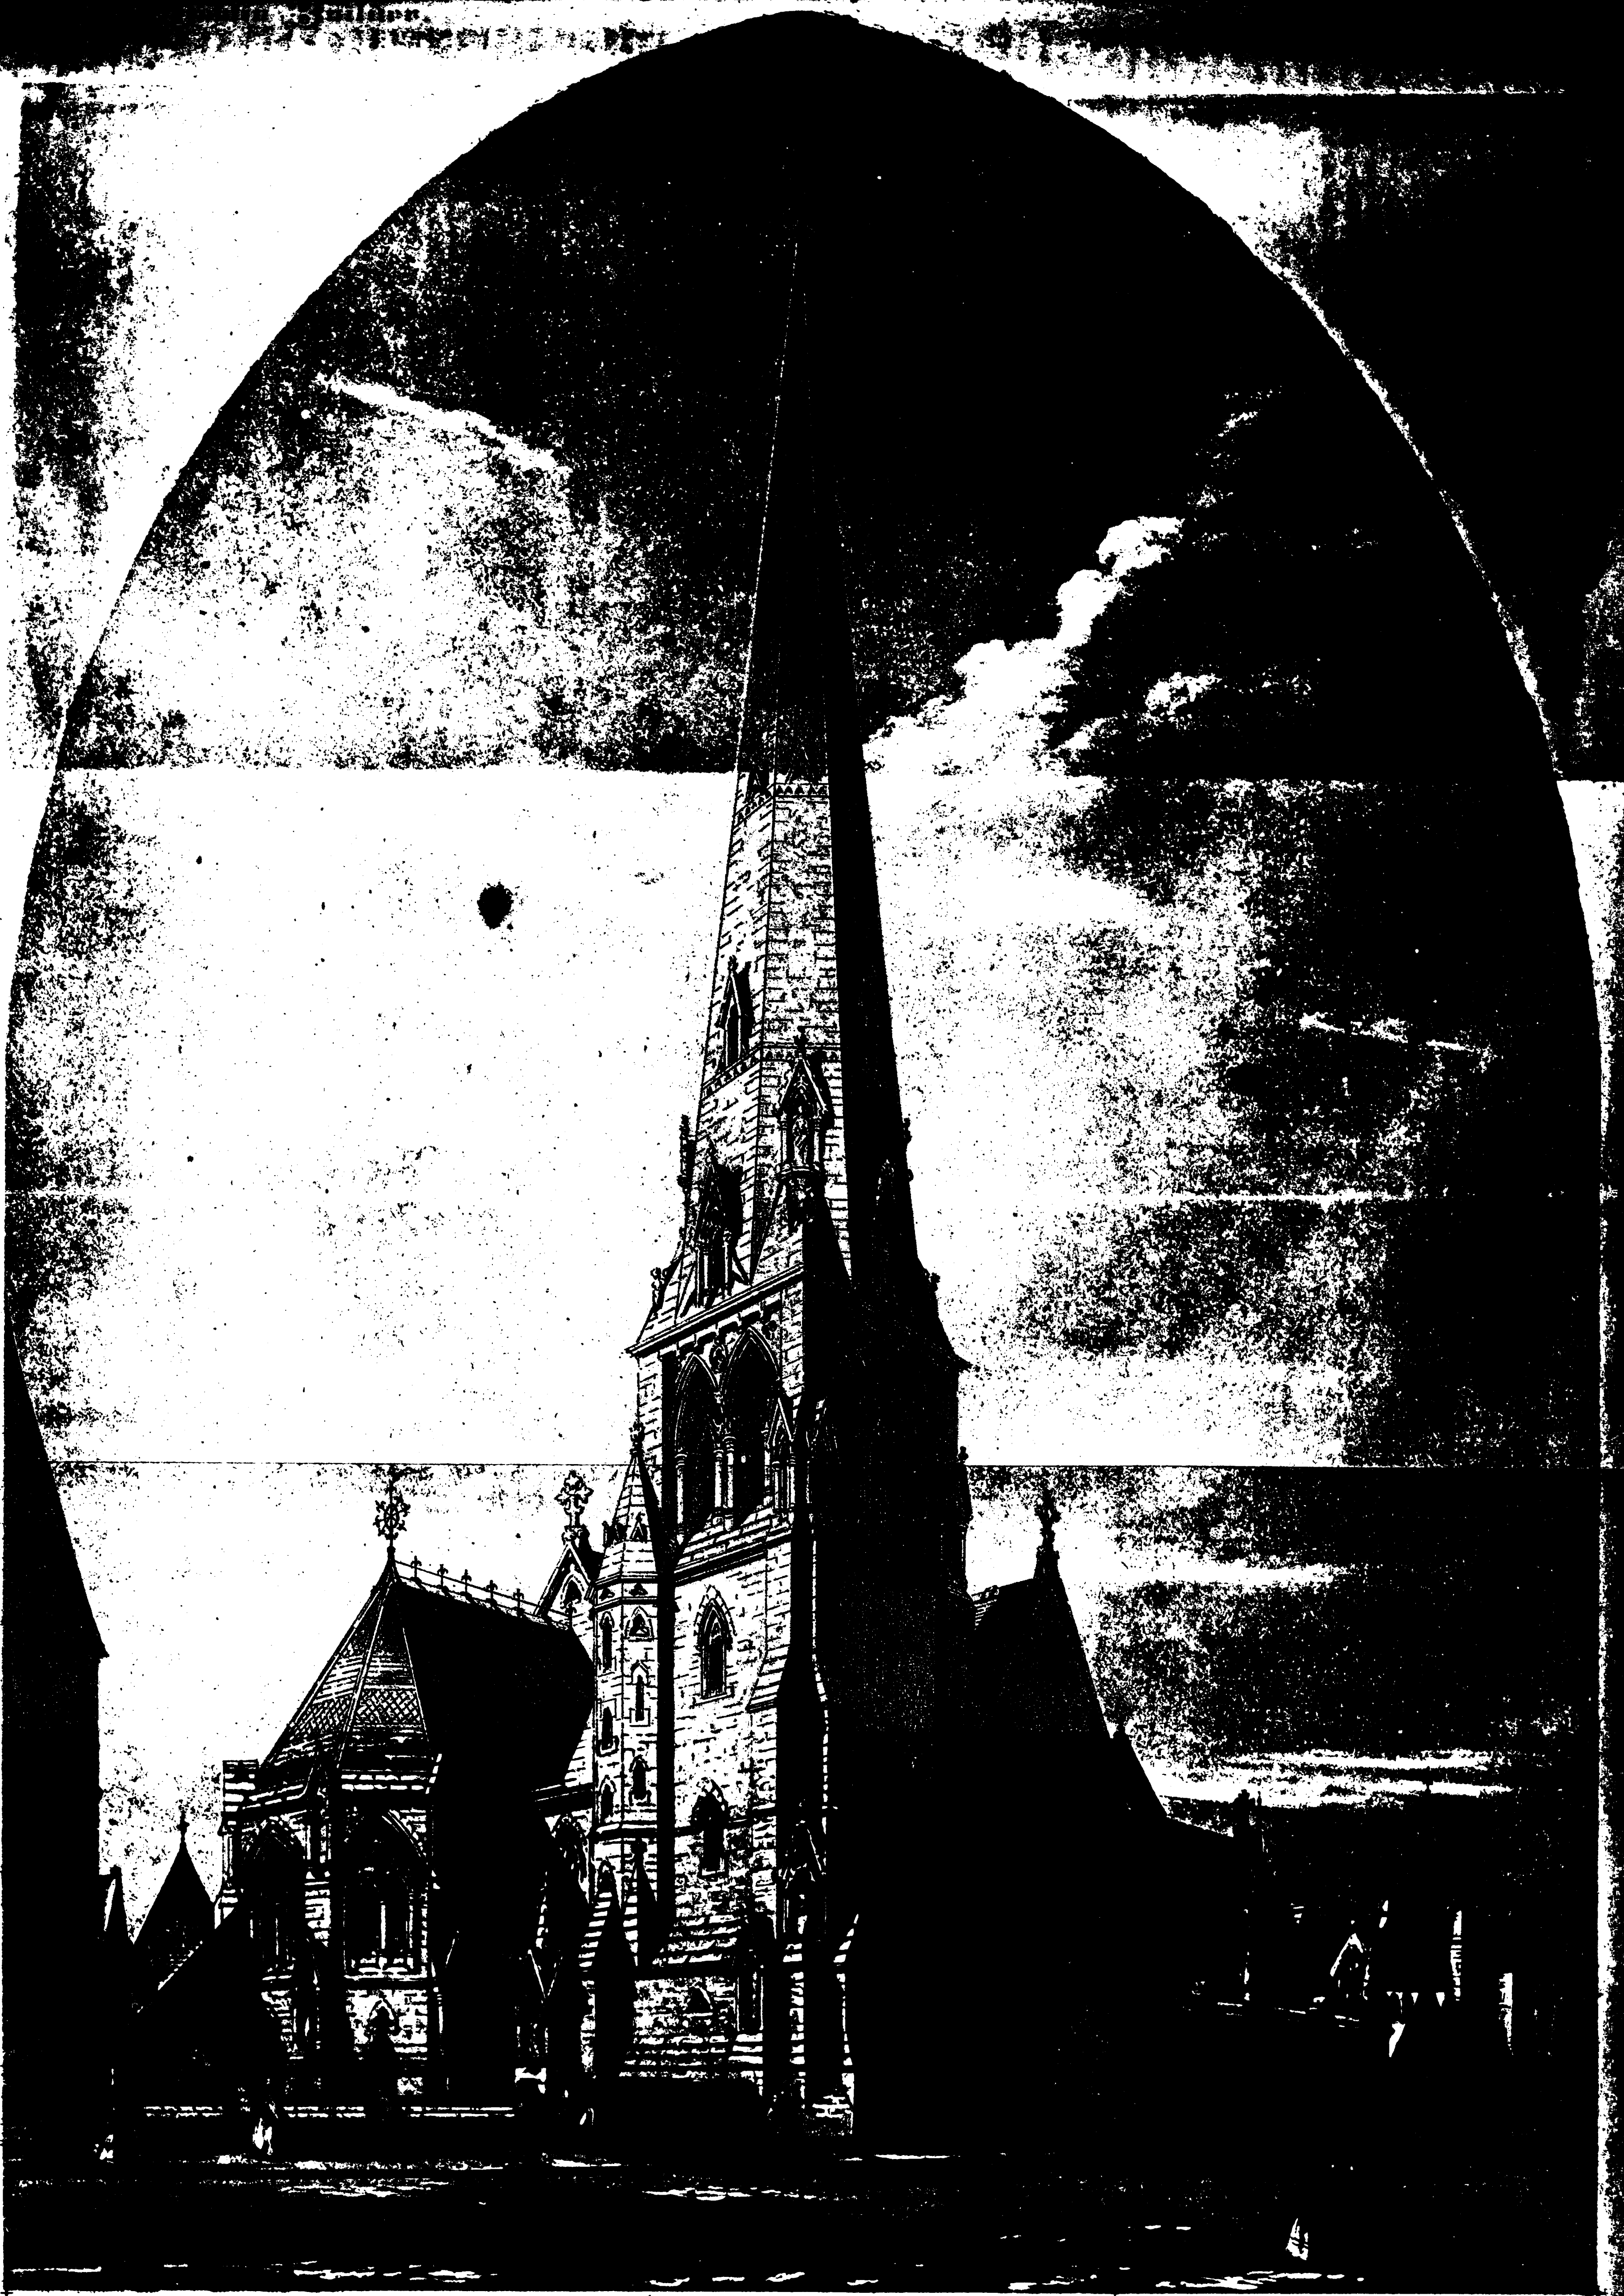
THREATENED DEMOLITION OF LONDON TOWERS AND SPIRES.

A project is now before the House of Commons in the Union of Benefices Bill, involving the destruction of some of the London churches, with their towers and spires, so replete with artistic beauty and intimacy of association with bygone architect celebrities. Political economy has been already carried to too great an extent of detrimental interference with the cause of art, but we can scarcely believe it possible that an "*enlightened*" tribunal in this "*enlightened*" age would, from observance of the former in the matter of £ s. d., consent to a wholesale vandalism. The Institute of British Architects has petitioned the House for the preservation of some *thirty-four* churches contemplated to be demolished, and including amongst others—perhaps less familiar to our readers—those of St. Mary-le-Bow, St. Michael's, St. Dunstan's (east and west), St. Bride's, St. Margaret's, St. Andrew's, &c. An amendment proposed in committee by Mr. Cavendish Bentick for the preservation of the churches of St. Stephen, Walbrook (Wren's masterpiece), St. Martin, Ludgate; St. Peter, Cornhill; and St. Swithin, Cannon-street, was carried (we trust *nem. con.*)

We are told by *The Builder* that the Institute held a meeting "*on the top of St. Paul's*"—Mr. Godwin in the chair—to consider the various towers and steeples that should be preserved, but however much we may laud the object of the committee, we certainly do not envy them their exalted position, however temporary.

THE SURVEYORSHIP FOR DERRY.

We understand that Mr. Williamson, C.E. (for many years surveyor for east division of Tyrone), and *not* Mr. Worrall, C.E., has been appointed to this vacancy, and entered on his duties. The information relative to Mr. Worrall being appointed, was conveyed to us as *authentic* previous to our last publication, and we must observe, that gentlemen ought to be more cautious in communicating *as a fact* to the public press that which, though probable, is not actually accomplished.



MESSRS LANYON LYNN & LANYON, ARCHTS MURISON, LITH. DUBLIN.

Intended New Parochial Church of St. Andrew, Dublin.

THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS

THE PROPOSED EXHIBITION OF 1861.

Judging from the initiatory steps taken by the Royal Dublin Society, and the encouragement so far afforded by the public, there seems to be every probability of a display of art and manufactures being secured to this city during the ensuing summer. The joint committee reports that "they do not advise the Society to take any action in the matter until a sum of £5,000 shall have been guaranteed"; that "the Agricultural Hall could by slight alteration to the floor and the construction of the galleries be made the very best for the purpose of the exhibition"; also, that "the exhibition should be limited to this hall only." It would seem to be but prudence for the Society to secure themselves against loss by the project, and therefore the required guarantee is a desirable precaution, but to the suitability of the Agricultural Hall exclusively, however modified, for the exhibition, we must take exception.

It is quite too stunted at present, even without galleries, will appear much more so when they are added, and at best will present a very make-shift appearance. The dimensions of the apartment are 235 feet in length by 106 feet 6 inches in width,—to our minds insufficient both for the accommodation of the numerous exhibitors that on a special occasion of this kind may be reasonably expected, and for the crowds that are sure to frequent the exhibition. The committee seek the co-operation of the Royal Hibernian Academy as regards the fine art department, but how far under the circumstances that body may lend aid would appear questionable.

We confess we have our misgivings as to the creditable result (at least) of this project, if not dealt with in a more comprehensive manner. The Society can afford much more space for the exhibition than the *mere* Agricultural Hall. The new Museum with its connecting arcade is completed. The National Gallery is sufficiently advanced to warrant the assumption that it too would be available against May, 1861, and why should not both these form part and parcel of the proposed exhibition? The preliminaries partake of paltriness, and in our opinion display much error of judgment, which we trust will be removed in time, so as not to afford room for censure upon the managing committee.

The Guarantee Fund reached on the 16th ult. the sum of £2,500, and is now considerably greater.

Donations to the Royal Dublin Society.—Mr. M'Cann, of California, has enclosed the sum of £50, being the first contribution of the Irish Fine Arts Aid Society of California towards the aid of sending a pupil to the Continent. Mr. W. Smith O'Brien has also enclosed a donation of £5, to be awarded to the native-born Irish artist who shall exhibit the best picture painted by himself, in either oils or water colours, at the proposed exhibition. It was resolved that the marked thanks of the Society be returned to him for same.

EXHIBITION OF BUILDING MANUFACTURES AND INVENTIONS, LONDON.

To such of our readers as visit the British metropolis we would suggest an inspection of the varied and instructive display of manufactures and inventions connected witn the building profession, at present accessible *free to the public* at the Conduit-street Galleries, off Regent-street. We were much gratified with the exhibition generally, and regard it as one (though of comparatively miniature type) having a most instructive tendency, not only on those within the pale of the profession, but on the general public; as well as presenting an encouraging field for the inventive faculties of manufacturers, and in a business capacity conducing to their interest. Amongst the numerous exhibitors, we would particularize those whose names are familiar to the readers of the Dublin Builder through its columns, and perhaps amongst the most prominently interesting may be regarded the mediæval manafactures of Messrs. Hart and Son, of Wych-street and Cockspur-street, and Messrs. Johnston, Brothers, of Holborn. The display of ecclesiastical furniture, of gas fittings, &c., by each of these firms is of a truly *recherche* character, proclaiming an excellence in the working of metals, in which the English stand admittedly unrivalled. The upholstery and parquetry work, by Mr. Arrowsmith, of New Bond-street, are also most attractive, and we had an opportunity subsequently of inspecting, at the establishment of the manufacturer, a variety of designs in solid parquetrie for flooring purposes, steps and landings, dados, &c. The exquisite delicacy and taste with which the most varied and beautiful patterns are produced by the combination of solid pieces of different woods ploughed, tongued, and grooved into each other, forming a solid, compact whole, is highly creditable to the manufacturer and patentee, from whom we may remark, *en passant*, we learned that he has received several commissions in Ireland, amongst which one from the Marquis of Sligo is probably not the least important.

Minton and Maw respectively stand prominent as usual in the encaustic tile department, and contribute a variety of new and beautiful patterns. Amongst the cement manufacturers we noticed the patent fire-proof cement by Mr. J. C. Part, of 186, Drury-lane, successor to Messrs. Stevens and Son, a material which is extensively adapted to building purposes, a fact which speaks for its excellence. Hobbs and Co.'s locks display an ingenuity of mechanism truly marvellous, and the indefatigable manufacturers are constantly introducing some novelty in construction. Pierce's stoves, known as the *pyro-pneumatic*, attract a considerable share of attention, and have been already favourably noticed in the columns of the Dublin Builder. Ransome's patent siliceous stone is moulded into a variety of architectural ornaments, and owing to such capability, combined with the permanent character of its texture, cannot fail to be universally adopted as a substitute for stone, where the latter may not be desirable for various reasons. The patent process for preserving stone, cement, &c., is now being applied to the Houses of Parliament, and we trust it may succeed in arresting the palpable decay in the stone work of that magnificent structure. Mr. Jennings, of Holland-street, Blackfriars-road, the proprietor of various patents, amongst which are several in the manufacture of pottery, irou shutter bars, &c., also occupies an important position in the exhibition. In conclusion, we may take the liberty of reminding the above-named gentlemen, as well as the numerous other exhibitors and manufacturers generally that there will be an exhibition in Dublin in May, 1861, and that we hope to see their establishments fully represented on that occasion.

SCAFFOLDING ACCIDENTS.

Mr. P. Sheridan writes as follows to the *Freeman* relative to the precautionary measures which should be adopted where scaffoldings are necessary:—

> "Another accident, which nearly resulted in loss of life, occurred this day at the building now going on in Parliament-street (the site where the late calamitous fire was), by the falling of the scaffolding. The awful accident in Baggot-street is still fresh in the minds of the public, and I would put it to the good sense of the corporation, as the representatives of the citizens, to at once appoint an inspector to examine all scaffoldings erected in public thoroughfares, the same as in London and all other English cities and towns. Would it not be the duty of the city architect?"

Mr. Guinness has subscribed £20 towards the fund for the sufferers from the recent accident in Baggot-street.

Sir Richard Griffith, Bart., who won the £100 prize at the last drawing of the Art Union of Ireland, has presented a donation of £25 to the funds of that body.

Mr. William Henry Deane, C.E., late surveyor of the South Riding of Tipperary, has been appointed by His Excellency the Lord Lieutenant to the surveyorship of the East Riding of the county of Tyrone; head quarters, Dungannon.

Carolan, the last of the Irish bards, is interred in the old church-yard near Keadue, and a slab has been erected to his memory by Lady Louisa Tenison, who has also caused the burial-ground and old church-yard to be enclosed in.

In the report read at the twenty-first anniversary meeting of the Ecclesiological Society, we find the following paragraph:—"We hear with extreme satisfaction that Mr. Guinness, a munificent citizen of Dublin, intends to restore the ill-used Cathedral of St. Patrick. Mr. Slater has nearly finished the works in Limerick Cathedral."

The Spanish Government is in the English market for the purchase of several thousand loads of oak timber, the contracts for which stipulate for the deposit of £17,000 caution money.

Notes of New Works.

The churches of Adare, Co. Limerick; of Rincurrin, Co. Cork; of Ashfield, Co. Cavan, and of Drum, Co. Monaghan, are being enlarged according to the plans and specifications by the architect to the Ecclesiastical Commissioners.

The War Department have advertised for altering the redoubts at Tarbert and Kilherrin on the river Shannon, in the Limerick district; for the erection of married soldiers' quarters at Island-bridge Barracks, Dublin; for renewing the paving of eight troop stables at Ballincollig Barracks, in the Cork district; and for fitting up five troop stables at Dundalk Barracks, in the Belfast district.

The new Roman Catholic church at Donnybrook for which drawings have been furnished by Mr. Patrick Byrne, architect, is to be early Gothic in style, and will consist of nave and aisles; extreme length 143 feet, and breadth 60 feet. There will be a tower and spire, surmounted by a cross, rising to an elevation of 140 feet. The site is the space bounded by the house known as the Rose Hotel, Church-lane, on the Stillorgan-road, and the present little chapel and the greater portion of it is now occupied by dilapidated houses.

New schoolrooms, male and female, have been erected in connection with Ballymacarrett Presbyterian Church, each 40 feet by 26 feet in the clear. The building is one storey, with open roof, and a portico, containing hall and cloak-room, to each school. Amount of contract, £440. The rooms are separated by folding-doors, to render them available for meetings. Their erection was unavoidable, as the site of the former schoolrooms is to be added to the church, which has become too small to meet the wants of that neighbourhood, and is now being enlarged by the addition of a transept, 60 feet by 28 feet, at the east end, which will include about 8 feet in length of the old building, and give increased accommodation to about 400 sitters. A session-room and entrance-hall are also being erected at the south end of transept, for which and the enlargement of the church the contract is £725. The erection of the schools and the enlargement of the church have been contracted for by Mr. James M'Cracken, builder. Mr. William T. Matier, C.E., architect, Belfast.

The erection of a new town-hall at Sligo is spoken of, and the newly-elected M.P., Mr. Macdonogh, Q.C., has promised to aid the project.

On the 5th ult. the foundation stone of a new Roman Catholic church to be erected at Ballytore, Co. Kildare, was laid by Archbishop Cullen. It will be in the early Gothic style, and after the designs of Messrs. M'Carthy and O'Connell, architects.

The Directors of the Dundalk, Enniskillen, and Londonderry Railway Company have received tenders for the execution of sundry works at the several stations, &c., on the Londonderry and Enniskillen line, according to plans and specifications by Mr. Fitzgibbon Louch, architect, C.E., Derry.

A mural tablet has been erected in the porch of the York-street Presbyterian Church, Belfast, to the memory of the late Rev. David Hamilton, the former pastor of that church. It consists of a large slab of Belgian black marble, 6 feet 6 inches high and 4 feet wide. The centre is cut out of Carrara marble, of pure white, in the form of a scroll of parchment, on which the inscription is cut. The work has been executed by the Messrs. Fitzpatrick, from a design by Mr. Robert Young, C.E.

The foundation stone of the new Roman Catholic church of St. Peter has been laid at Belfast, and is thus described by the *Morning News*:—The site—a square plot bounded on every side by streets—was gratuitously given by Bernard Hughes, and is large enough to contain a parochial house, schools, &c., in addition to the edifice. The new church will be cruciform in plan, It will consist of nave, terminated by a pentagonal apse, lighted by lofty three-light decorated windows; side aisles, terminated by side chapels, west and lateral porches, sacristies, &c. The west end will have much the appearance of some of the French cathedrals, divested of their intricate and elaborate carving and sculpture. The central porch will be entered by one of those double doorways common to the English and French churches, with a column in the centre, and carving in the spandril beneath the label moulding, which will span the double arches. The central porch thus terminating the nave, will be flanked by towers, nearly 22 feet square, and in height to the top of their crosses about 115 feet. The extreme length over the walls will be about 176 feet by 66 feet—*i.e.*, of nave and aisles. The ridge will be about 70 feet from floor level. The style will be that of decorated Gothic, and those who have seen the drawings anticipate that the building will be, when finished, one of the architectural ornaments of the town. It will be built of Scrabo stone, with Co. Tyrone freestone dressing. The amount of the contract for the edifice, irrespective of internal decoration, is £10,192.

A new church is to be built at Kilronan, and the first stone has been laid. The site was presented gratuitously by Mr. E. R. Tenison, and Messrs. M'Carthy and O'Connell are the architects.

A new Roman Catholic church is to be erected in Belfast, on the Falls-road, in the decorated Gothic style, at a cost of £10,192. Length outside, 176 feet; width, 66 feet; ridge, 70 feet above floor. It is to consist of aisles, nave, and porch terminating, the latter flanked with towers, which will rise to a height of 115 feet.

A small mural fountain of bronze has been fixed in the boundary wall of the University in College-street, which would seem to signify that the unsightly wall so frequently complained was destined to be a fixture.

Tenders are required for cleansing, colouring, and painting the interior of Lismore Cathedral.

The fund for the erection of the testimonial to the late Dr. Crozier, of Banbridge, of the Franklin expedition, amounts to about £600.

We understand that competition designs were advertised for a new church at Sydenham, Belfast, offering a reward of £20, and that the only competitor was Mr. Barre, whose designs have been adopted. A correspondent complains that the advertisements were not inserted in a professional journal.

We understand that the line from Youghal to Cork will be opened on the 1st January, and the branch to Queenstown about the 1st March. It is understood that the Great Southern and Western Railway Company will form a junction with the Youghal line, so as to facilitate the forwarding of passengers and goods from Dublin to Queenstown.

A contract has been entered into with Messrs. Smith and Knight for the construction of a line of rail from Castlerea to Castlebar. It will be open to Claremorris on 15th December, 1861, and to Castlebar on 15th August, 1862.

Vigorous efforts are being made to connect Downpatrick and Newry by railway. All the accommodation that has existed on this line has been an outside one-horse mail car, with an occasional passenger now and then, but as frequently without any. It is intended to start from the station at Downpatrick, pass within three-quarters of a mile of Clough, 1¾ miles from Seaforde, running along the west shore of Dundrum Bay, close to the towns of Dundrum and Maghera, and within 2 miles of Newcastle, 1¼ miles from Bryansford, and approaches Castlewellan, from which it will only be a quarter of a mile. Crossing the River Bann at M'Comb's-bridge, it passes close to Rathfriland on the north, and, crossing the canal, terminates at Edward-street in Newry, at the station of the Newry and Armagh and Warrenpoint Railways. It is also proposed to have a branch from Mount Kearney to Gorah Wood, for a connection with the Dublin and Belfast Junction at that point. The length of the main line appears to be about 23 or 24 English miles, and as only one line of rails will be necessary, the cost will probably not exceed £150,000.

THE WATER WORKS QUESTION.

The expected inquiry by the Royal Commissioner, Mr. Hawkshaw, C.E., was commenced in the City Hall on the 21st ult., and continued for three subsequent days, during which the Commissioner, in a most painstaking manner, went through a mass of evidence to aid him in deciding this long-vexed question, and which we trust now will meet at his hands a speedy and final solution. In the following will be found a comprehensive summary of the proceedings. The Town Clerk having read the Royal Commission, and the Commissioner stated the objects of the inquiry, tabular statements Nos. 1 and 2 (which we deem unnecessary to publish, having been so fully treated of already in the columns of the Dublin Builder), respectively explaining "the state of the present" and "the necessity which exists for an improved supply," having been submitted, and other preliminaries arranged, the examination of witnesses was proceeded with.

Dr. Apjohn deposed to being a professor of chemistry, and having examined the several waters from which the city is supplied, and twenty-three other waters; made the analyses with the greatest possible care, and can speak with the greatest possible confidence as to the accuracy of them; sent in a detailed report to the corporation, but as detailed reports are not of much practical use, have constructed a table in which are exhibited the total amount of ingredients dissolved in the water. Dr. Apjohn then read a statement and handed in the following analysis:—

	Total matter dissolved.	Organic matter.	Hardness.
Grand Canal—mean of seven—analysis	20·78	·95	15·9
Royal Canal—mean of five—analysis ..	20·76	1·64	14·1
Liffey—mean of eleven—analysis ..	8·62	1·77	6·1

Dr. Wilde stated that he was engaged in the preparation of the census of Dublin, in 1841 and 1851; the map now produced is attached to that portion of the report; in the map the localities are classed according to 1st, 2nd, and 3rd class houses; the result of his experience is, *that mortality is much greater in inferior houses in which large numbers of the population are crowded together with a defective supply of water and sewerage;* formerly, when living in

Stephen's Hospital, had extensive opportunities of knowing the nature of the supply to the poorer localities; the supply was very defective at the top of James's-street and the Liberties; the sanitary condition of the inhabitants is *very much affected by the water supply*—next to air the most; has very frequently been present at the opening of water pipes in the streets of Dublin; saw great quantities of spongillæ, of a fœtid nature, pumped in such a way that showed they must have been in large quantities in the pipes; saw them pumped up in the neighbourhood of Merrion-square and Stephen's-green—in fact, out of the pipe opposite to his own house; brought in some of the water containing those spongillæ for examination, and it became unbearable in the course of 24 hours; they render the water quite improper to drink; is not an authority as to filtration, but is of opinion that filtration would not remove the objectionable characteristics from the water; had opportunities of examining the water supplies of other cities; in Stockholm, although it is the best ventilated city in Europe, the mortality is the highest in any city in Europe, arising (as one must come to the conclusion from careful investigation) from the total inefficiency of the water supply; believes there was not an instance until very lately of a water-closet in any house in Stockholm; water-closets should be more frequent and certainly should not be subject to any tax; from experience as a physician in practice in this city, knows the poorer classes are not sufficiently supplied with water; certainly about Townsend-street, and in other parts of the city, the inhabitants are not supplied with water; if there is not a supply of water brought to each house, no matter how many fountains you may have, you certainly will not keep disease out of their dwellings, for the people will not go to the fountains; they will use the dirty water again and again; would bring the water to every "flat" which might be inhabited; feels the necessity for a supply of pure water in the city; we want water brought through a channel that will fill the tubes at such a pressure as to economise taxes, which are now increased by having forcing pumps and persons to work them, as will also, in case of fire as well as for sanitary purposes, ascend to the tops of our houses.

The Commissioner—I have myself noticed this spongy substance at the outlet of one of the reservoirs, but I could not judge from that whether it run into the heart of the city through the tubes. It is your observation, however, that this objectionable substance does run into the heart of this city?

Dr. Wilde—The last place I saw it was at Stephen's-green, at the corner of York-street; shortly before that I saw it in the street I live myself—Merrion-square; when the main is turned on the substance springs with great force into the air, and there can be no doubt that it renders the water unfit for use; Merrion-square is distant about a mile by the walk from Portobello basin, the pipes running circuitously make the distance longer; (in answer to Commissioner) has not examined the spongella so as to give a scientific description of it; the odour of the substance is most offensive, the taste perfectly unpalatable, but the smell even worse; on both sides of the river the want of water is felt; the dwellings of the poor are crowded, a couple of families, perhaps, residing in the same room, and they *use the same water again and again, from not having a sufficient supply; from laziness or other causes* they will not go to the neighbouring fountains; they will scarcely go to the cellars below for it, and they use the same water *for washing and culinary purposes*, as well as their *ordinary ablutions*.

The Commissioner here asked Dr. Apjohn whether he had examined the spongy substance mentioned.

Dr. Apjohn said he had, some time ago, but does not remember the detail of his statements in reference to the spongella, but he could speak generally of it as being a highly objectionable and impure substance, with a smell exceedingly offensive.

Dr. Rawdon M'Namara examined—Is a Fellow of the College of Surgeons and Licentiate of the College of Physicians in Ireland; Professor of Materia Medica in the Royal College of Surgeons, and Examiner on the same subject in the Queen's University in Ireland; is a surgeon to No. 3, City Dispensary, in the South Union district; should say that about 10,000 of the poor inhabitants of Dublin pass yearly through his hands; visits a large number of cases at their dwellings, and believes there are few persons in Dublin better able to speak of the sanitary condition of the poor.

State the result of your observations to the Commissioner.—My opinion is this, that the supply of water to the entire of the city is deficient both in quantity and quality, and exeeedingly so to the poorer inhabitants; conducted a very extensive system of filtration yet in existence at his house; began about 12 months ago; lives at 95, Stephen's-green, where the supply is derived from the Portobello basin exclusively; the quality *of the water is infamous;* the poor have no supply of water, nor in the majority of cases no means of collecting water; have to go to fountains to obtain it, with vessels insufficient for the purpose, and it is kept in their rooms until required for use, and thus is very bad and insufficient for sanitary purposes, owing to the difficulty of obtaining a proper and sufficient supply; thinks that fully 80 per cent. of the houses of the poor have no means of getting water except in the way described; owing to the difficulty the poor have in obtaining a supply of water, and the way it has to be kept in their rooms, it is calculated seriously to affect the health of the inhabitants; bad water is most injurious to the health, especially as regards cutaneous diseases, which are very much fostered by an insufficient supply of water; present supply is quite insufficient for sanitary purposes; there ought to be water in each house, and it would promote their comforts and improve the health of the city in a way that cannot be calculated; the higher classes may have a better supply to a certain extent, but are not supplied in a satisfactory manner; there may be a sufficient supply in private dwellings, but not in a way to give satisfaction or ensure comfort; the pressure at present cannot carry the water to the tops of the houses; if the supply in the houses of the rich be sufficient, is must be collected in the basement storey, for the pressure cannot carry it beyond a certain height (believes 10 feet); the result must be unsatisfactory; though the supply may be better for the rich, the quality of the water is the same, and many cannot drink it, but send to pumps for water to drink; could not drink it in his own house without filtration; water has to be forced up to supply water-closets; never saw a house saved in Dublin when there was a serious fire, but they have been invariably destroyed by the fire in consequence of the insufficient supply of water; speaks from experience in visits among the poor; since 1846 I have been brought into connection with the poor as a medical man; people who know the quality of the pipe-water prefer getting water from pumps; a great objection is to have the water collected in cisterns, whence the sediment is frequently drawn off through the cock at the bottom, and thus consumed.

Dr. Apjohn read as follows his report to the corporation upon the quality of the water supplied to the city through the basin at Portobello, and the water pipes which issue from it:—

"Water	2·20
Organic Matter	9·71
Sand	10·20
Per Oxide of Iron and Alumina	3·50
Carbonate of Lime	74·20
Carbonate of Magnesia	·19
	100

"The amount of the organic matter, it will be seen, was very considerable, reaching nearly 10 per cent. I may add that it was of two kinds, a thready or piliform product, which, when examined under the microscope, appeared to be a confervæ or fresh-water algo, and a munbranoccous substance of a highly allulor structure, having some resemblance to certain of the sponga. This latter exhibited two appearances occurring on the sides of the basins and interior of the mains, partly as an incrustation of slight thickness, and partly as projecting growth of the size and nearly the shape of the human fingers. Their growths were recent, were of a greenish colour, and, seen through a lens, appeared studded over, particularly at the extremities, with low conical projections. The organized products just described were penetrated by numerous maggots, which had the facility of spinning threads like those of the spider, executed rapid movements, and were capable of inflicting bites. When a mass of the mixed organic matters just described was placed in a basin of water, putrefaction rapidly set in, and in 24 hours an insupportably offensive odour was evolved. From what precedes it is obvious that the incrustation which has been the subject of examination is composed partly of the earthy carbonates existing in the water, and which are so prone to separate from it, and partly of a peculiar vegetation or growth which, under favourable circumstances, springs from such incrustation. If the earthy sediment which falls was destitute of organic matter, it would probably not produce conferro or sponga; but the opposite being the case, in consequence of some of the organic matter of the water always falling with the carbonate of lime, a sort of compost is formed, which, when aided by a suitable temperature, brings into rapid development the forms of organic life which have been described. To remedy this state of things I do not know that anything effectual can be done, except to deprive the canal water, before it enters the mains, of the earthy and organic matters which are prone to separate from it. This, as I mentioned to you on a recent occasion, is a thing which can be done, though it has not, I believe, as yet been attempted on such a scale as would render the process applicable to so large a city as Dublin."

On one occasion saw spongilla in James's-street basin.

Mr. M'Mullen—In an analysis which you made some years ago of the water of the Grand Canal, you state the water was exceedingly pure.

Dr. Apjohn—I made this analysis, and I believe it to be perfectly correct, it was carefully made; on looking now at them which I have not seen for many years, there appears to have been in the water of the Portobello basin a proportion of 3 decimal, 3 of organic matter; it was after that I obtained the knowledge of the spongilla, and if I had seen it then as I have seen it since, I would not have made the statement which you have produced; I admit I attached too little importance to the amount of organic matter in the water; at that time I did not believe it to be so prejudicial to water as experience has taught me it is.

Mr. M'Mullen—With respect to the Grand Canal water, which you then analysed, you say—"I am quite certain that the quantity of animal and vegetable impurities in the canal water—impurities of which no natural water is ever destitute—does not exceed that indicated by the analysis. I may add that their relative proportion is much too small to leave any room for apprehending that their presence can confer upon the water properties which would render it either disagreeable to the taste or injurious to the health." How does it come that your opinion is so much changed?

Dr. Apjohn—The facts are not impugned. The analysis was carefully made. I believe I was in error in the statement I then made as to the effect of the organic matter upon the water. That report was made fifteen years ago, and changes have taken place since then.

The Commissioner—Had you noticed the spongilla in 1845?

Dr. Apjohn—No; I never even heard of it.

Dr. John Ryan examined—Am a doctor of medicine and a licentiate surgeon; is well acquainted with the Liberties; the supply is most insufficient, and extremely bad; it was particularly bad some years ago until the old wooden pipes were taken up and other pipes put down; knows the portion of the Liberty supplied by the corporation, the water is insufficient in quantity and very bad in quality; is in the habit of visiting the sick poor in their homes; there cannot be a greater cause of disease amongst the poor than want of pure water; in Plunkett-street there are about fifty houses, with an average of fifteen persons in each house, making a total population of about 700; all the people are dependant for water upon one fountain in the street; there is only one house in the street in which there is pipe water; was a member of a relief committee in the famine years, and of a sanitary committee, and at that time ascertained there were 800 persons living in the street; would take the number now at 700; has seen spongilla taken out of the water pipes; on the part of a great number of persons, protests against the continued use by the citizens of canal water; it has been especially impure during the last month; the water is rendered impure from many causes; has seen dead dogs and cats in the Grand Canal, and filth pumped into the canal from boats lying within the city boundary; boatmen are in the habit of distributing manure along the banks of the canal to persons, and they make up the weight by water; then leakage takes place, and that foul leakage is pumped into the canal; this occurs even as far as the 8th, 9th, and 10th locks, where it was said the water is pure.

To Mr. M'Mullen—I always thought pure water could be had at the 8th and 9th locks, until I went up there and inspected the water; on one occasion I saw the water extremely brown in James-street Harbour, and weeds and various impurities floating about; struck by this I made inqury, and found that it was caused by a steam boat which had just before come in; I have not seen this boat at work, but just after coming in.

The Rev. E. S. Abbott, Rector of St. Mary's Parish, examined—Previously lived in St. Michael's, St. Michan's, and St. John's parishes; St. John's parish is situated in a very poor neighbourhood; visits the poor frequently at their own houses, and generally speaking, they have no supply at all; there are frequent epidemics in the locality named; is of opinion that in a moral and sanitary point of view it is of the utmost importance that the poorer classes should have a proper supply of water; never heard any complaint of the quality of the water which they do get from the fountains; it may be their ignorance, but never heard them complain; there are very few pumps in the poorer localities.

Rev. Joseph Horgan, C.C., examined—Is one of the curates of St. Laurence O'Toole's parish, which is inhabited by about 3,000 of a very poor population; constantly attends at these people's houses; the result of observations as to the quantity of water supplied them is, that they have very little opportunity of being provided; believes the fountain in Newfoundland is the only public fountain in the locality; there are other fountains, but it is optional with the parties to allow the people to them; there is a supply of pipe water in the houses of the better classes; there are about 3,000 in the parish who have no supply except from the fountains; as to the quality, it is very inferior; observes in the water that there is a deposit in it after night; that it is offensive to the smell very often in wet weather; the people must go out to the fountain for water, and in bad weather they are reluctant to do so; has heard it said if the water was conveyed into the houses of the people that it would create uncleanliness, as the water would be allowed to run about, but thinks the very reverse.

Very Rev. Dr. Spratt examined—Has been a clergyman in the city since 1823, and endeavours to take a considerable interest in the social condition of the people; is constantly in the dwellings of the poor; the supply of water to them as to quantity and quality is very bad; is nothing like a sufficient supply of water to the poor; very few of them are supplied with water in their own houses; pipes are very rare amongst them, and they are often inconveniently placed, sometimes in a "huxter's" shop, for instance, the result of which is that the pipe is more or less used to create patronage; a constant supply of good water would improve the morals of the people; believes we would not have half the drunkenness which we have in the city if we had a proper supply, because the water is so bad that the people won't drink it; has often asked the people why they relapsed into drunkenness, and they always say that the water was too bad to drink it; when passing a fountain, heard obscene language used in the hearing of children, and at a very late hour at night; at the fountain in Kevin-street large numbers of poor creatures may be seen collected, waiting for their turn to get a supply of water, many of them having come from a distance, and with very little clothes on them; does not know whether the supply to the fountains is continuous or not; there can be no second opinion as to the moral and physical deterioration of the people from the want of a sufficient supply of water; has often seen dead dogs and cats in the canals, and impure stuff thrown from the boats into the canals; the boatmen have said that they have no convenience—no water closets in the boats, and all their night soil is consequently thrown into the canal; does not know what filtration may take place in the basin; has a strong objection to taste or drink the city pipe water; community have a private pump for their own use; for some time it was open to the public, but had to give this up as it became a nuisance; crowds came from all distances to get the water, which was of excellent quality, coming from a spring; 1,000 and 500 people might be seen at this pump at a time; persons in reduced circumstances are ashamed to show their poverty by going to the public fountain again; in many instances poor Catholic families, who are obliged to go to Mass on Sundays, stay away; they do not wish to exhibit their want of clothes by going to the fountain for water to cleanse themselves; the poor are obliged to economise the water as much as possible; has been in rooms where the water was used for three or four different purposes, and only thrown out when it could be used no more; the water in some rooms emitted so bad a smell, that I was obliged to leave; believes the new public fountains in the city to be a great blessing, but the water has a bad flavour; country people, used to good wholesome water, object to it; they cannot, in fact, drink the pipe-water in the city.

The Rev. Bernard M'Donnell gave similar evidence respecting Paul's parish, in Church-street, Bow-street, Hammond-lane, Manor, Prussia, and Aughrim-streets, &c.

Mr. John M'Mullen stated that he wished to direct attention to the analysis of canal water taken from the basin at Portobello, which was made by Dr. Apjohn some years ago. Dr. Apjohn was now of opinion that the water had a good deal changed, and he (Mr. M'Mullen) was not, therefore, to place such reliance on that analysis as he had been in the habit of doing heretofore. The amount of organic matter discovered by this analysis was so very small that he did not consider it could at all influence the quality of the water, and to that opinion he still adhered.

The Commissioner said this analysis was made some 15 years ago; he should like to have evidence on the present state of things. The principal objection raised to the canal water was the accumulation of vegetable matter at the mouth of the pipes; but if the suggestions of Mr. Hawksley were adopted, and that the water was filtered through sand, he did not entertain a doubt that all the seeds of vegetable matter which were carried into the pipes and grew there would be effectually excluded. The principal supplies to the Grand Canal were from springs, and, in point of fact, none but spring water was supplied to the city. With respect to the extraneous impurities which had been referred to, the canal company took every precaution to prevent them; the boat propelled by chains, which had been mentioned, was a recent invention, and, if it succeeded, it would be highly beneficial to the water, inasmuch as it would root up the vegetable matter, which would float down to the docks and be carried away.

Mr. William Pare, proprietor of the Seville Iron Works, produced a calcareous deposit which he had taken about two years ago out of a pipe which led to one of his boilers. It had accumulated in the space of twelve months. The water in the cistern which supplied the pipe was filtered through sand; the water in the pipe was generally heated to about 60 degrees.

Mr. Thomas Trouton, agent to the Royal Exchange Insurance Company, deposed to the insufficient supply of water in case of fire. A vast deal of property had been lost, to his own knowledge, on this account. He would suggest, as a remedy, high pressure.

The Rev. Thomas Doran, C.C.; Rev. Gregory Lynch, C.C.; and the Rev. Dr. Stanford, Rector of St. Thomas's, were severally examined, and testified both to the inferiority of the quantity and quality of the water supply.

Mr. William Digges LaTouche, chairman to the Grand Canal Company, was next examined, and stated that he was of opinion that the charges against the quality of the water arose from there being no filtering machine at the basin; the basin at the north side was supplied with a filterer, and therefore they did not hear the same amount of complaints as came from the south side; the Corporation, in his opinion, did not attend sufficiently to the cleansing of basins; the citizens whom he heard discuss the question did not think there had been fair play given to the water during the past year.

To Dr. Gray—The Corporation presented a bill to get water from the canals, in the present year, because they had not succeeded in being able to get it from other sources last year; the Corporation was in negociation with our Company for a supply of water before they went elsewhere. Mr. Neville applied to us to cleanse the bottom of the canal, but we could not do so without running off all the water. I never observed bubbles on the canal arising from fœtid matter in the bottom; we refused to give the Corporation a preferential and guaranteed supply, because, in the first place, we did not think the price proposed was sufficient, and next, because we would have great difficulty in settling with mill-owners; I do not think the Corporation had a right to demand from us a guaranteed supply. We furnished them with evidence as to the amount of supply we could afford, and it was for them, by constructing reservoirs, to preserve a sufficient quantity of water in time of scarcity.

Mr. Robert Mallet was examined. He gave it as his opinion, from his own experience, that no amount of filtration would, in the months of November and December, make the canal water pure and wholesome.

The Commissioner said the Grand Canal Company should be prepared to lay before him a definite, binding proposal of what they intended to do, if they wished that he should take any practical action on their suggestions.

Mr. LaTouche said he would be prepared with evidence as to the quantity of water they could supply, and it would be for the Commissioner to draw his own conclusions. As to any definite proposition he was not prepared to make any at present, but he would consult his board on the subject.

Mr. Bateman made explanations to show the purity of the streams in the neighbourhood of Ballysmutten, where he proposes to construct his reservoir, and read Mr. Yeates' return of his rain guages, from which it appeared that from the 23rd of February to the 6th of June, 1860, the rain at Dublin was eight inches. From the 23rd February to the 21st August, inclusive, the rain fall at Dublin was 17 inches; at Blessington 21 inches; at Ballysmutten, on the site of the proposed reservoir, 27 inches. This showed an increase over Dublin of 10 inches. It would appear that 50 to nearly 80 per cent. more rain fell at Ballysmutten than at Dublin. At Manchester, before the introduction of soft water, the city was supplied with hard water, which favoured the growth of a small fresh water mussel, which thickly line the reservoirs and pipes. There were myriads of them, and they lay in the pipes as thick as paving stones. There were caused by the large quantity of lime in the water. He was curious to see what would be the effect of passing water without lime. This was done ten or eleven years ago, and the result was that these mussels had entirely disappeared. There was no longer anything from which they could make their shells, and for years on their discharge the small pipes were choked with them. If soft water were supplied to Dublin in place of the present hard water, which probably favoured the growth of spongillæ, they would probably disappear.

Mr. Thomas Mallett, C.E., proceeded to place his plan before the commissioner. He proposed that the supply should be taken from the Dodder, the water to be collected in three reservoirs, and the estimated cost £184,000. Mr. Mallett laid several documents before the commissioner, setting forth the estimated expenses of the various items, and proving the practicability of his scheme.

Mr. Edward Clibborn stated he had lived for 50 years close to the river Dodder, and it had been the complaint made by persons living there, that from some cause or other the actual supply of water in the bed of the river was decreasing gradually, and to such an extent that many feared the time would come when there would be little or no water. His own experience of the Dodder for nearly half a century was, that the diminution of water increased annually.

Mr. Christopher Mulvany, Engineer to the Grand Canal Company, proposed the supply from the two canals; in 1840, a scheme was brought forward to make a certain reservoir, and the corporation applied to him to make a counter-project, and he then gave the matter consideration; he proposed to make a reservoir from the canal, whose elevation would be 176 feet above it; in 1859 the corporation proposed the scheme of supplying the water from the two canals, but this, with the other, fell to the ground; since that time he was very much inclined to alter his view of taking the supply exclusively from the one canal; this alteration of opinion arose from observation of the increased population of Dublin; he was disposed to adopt the two canals as the surest and best means of supply.

The Commissioner—Do you consider the canal water to be of the best quality?

Mr. Mulvany—I will not enter into that question; it is the best source as to economy and as to quantity; I believe it can hardly be said the water is bad, for there is an experience of it of 50 years; the Royal Canal would supply 4,500,000 gallons daily on the driest day, and the Grand Canal, for a very short period, from 4¾ millions to 5 millions daily, also on the driest day; one of the supplies of the Grand Canal is the large river, which has its source in the west range of the Dublin Mountains; the estimate of the quantity of water from the Grand Canal was based on a calculation of the least yield of this source; on the 3rd August, 1857, the yield was 2,836,200 gallons a-day, while on the 13th of the same month, after a fall of rain, it was 5,000,958; the plan showed the area of the lake which was the principal feeder of the Royal Canal to be 2,500 acres, and the area of the whole rain-basin of the lake, including the lake itself, is 7,943 acres; in addition to that reservoir, there is a stream which the Midland Great Western Railway Company have full control of, and which flows into the Royal Canal about 10 miles east of Mullingar; this stream yields 2,000,000 gallons daily; it yielded that quantity in the dry year 1859; taking these two canals as a source of supply, I think it would be amply sufficient for Dublin; this would not occasion very much interference with mill power; my proposition is, that the water should be taken from between the 6th and 7th locks; I do not know whether the canal company would make a guarantee in the matter; I do not attend here officially; I suggest that the Corporation should construct a reservoir; I think that an understanding could shortly be come to between two companies like the Canal and Corporation, with respect to authority and control over the works; in February last the heads of the companies met, and came to an understanding to give ten millions of water every day; I think the two Canal Companies are willing to give this water for£ 4,000 per annum, and that in addition the Corporation should make the reservoir so as to give out this water at a uniform quantity of ten millions daily; I have estimated the cost of the reservoirs, and I think that £140,000 would be sufficient for the purpose of conducting the water into Dublin; I do not think the reservoirs by themselves should cost more than £60,000; the cost for mains would be about £55,000, £60,000 for reservoirs, including filters; the length of the mains from where I calculated was for each five miles; I have been engineer to the canal for 14 years; taking the water between the 6th and 7th locks, the elevation is about 150 feet; I see nothing to prevent the canal company from giving what may be called a reasonable guarantee: I think there can be no doubt that this quantity of water could be given; I think a reservoir holding 200 million gallons of water would be sufficient; just immediately at the tail of the proposed embankment of Mr. Mallet's there are very large landscapes, and looking at the formation of the valley, there is a great quantity of sand, and it strikes me it would be a very dangerous place to put an embankment of any height.

Mr. Hawkesley said he attended on behalf of the corporation; he became acquainted with the subject in 1855; the first plan proposed was that of Mr. Mulvany, which was thought inadequate, as it did not give sufficient pressure for the districts in the neighbourhood of Dublin; it only gave a pressure of 168, whereas it was considered that 200 were required above the ordnance datum; the next plan was that of Mr. Thomas Mallet, known as the "Dodder Valley scheme;" his great objection to that plan was that the rainfall was not sufficient to give them grounds for supposing an adequate supply could be obtained; the evaporation, which was equivalent to 15 inches in this latitude, being deducted, would render it insufficient; fourteen inches and a-half of rain in the district from which this water was proposed to be taken by this plan wonld supply 36 persons per acre, but they required 12 millions per diem; the population of Dublin and districts amounted to 350,000, and it was necessary to have a supply for 400,000, allowing for increase; but, in supplying this, they were in peculiar difficulties, the brewers having no stream of their own; the catchment basin of this scheme was only 6,000 acres, and it was, therefore, impossible for him to approve of it; the next scheme was that of Mr. M'Lean, who proposed to supplement the water of the Grand Canal by taking a supply from the Liffey, at a place called Morristown, and then to draw from the canal at the fifth lock; so far as supply was concerned, that was sufficient for all; but it proposed to draw the water from a level too low for the purposes of the town; I did not make any report upon that, as I received no communication on the subject; the next scheme was that of Neville, in 1849, who proposed to supply from the 12th lock, for 250,000 population, at the rate of 3 cubic feet per diem; I then was induced to visit Lake Owel, and I ascertained that the supply was wholly insufficient; the evaporation on the surface of the lake is fully equal to the amount of rain falling upon it; this lake is different in position from the other reservoirs suggested; it might be possible to procure a supply from that lake equal to 15 inches per annum; 12 inches would supply 30 persons to the acre; the scheme, therefore, of Mr. Neville was found to be perfectly inadequate; I may add that the water of Lake Owel is very good indeed; the next plan submitted to me was one of Mr. Louch, in 1850, and he proposed to establish a reservoir on the Government gardens in the Phœnix Park, at an elevation of 180 feet, which also related to the Royal Canal, but at too low a level; here I may mention that I think too much importance has been attached to what is called "degrees of hardness;" very good water is that at 8 and 9 degrees; the next step taken was that of the corporation, in recommending the joint plan of Mr. Mulvany and Mr. Louch; the next scheme was Mr. Brassil's, to take the water from Poolaphoca at an elevation of 170 feet; the reservoir Mr. Brassil proposed was too small; I have had a great deal to do with the formation of reservoirs, and I can only state that the experience I have gathered induces me to say that (as proposed) a great deal of unnecessary expense would be incurred by constructing a reservoir at Ballysmutten; the first ground upon which I refrain from recommending this reservoir is because it would be impossible to estimate the expense of making it water-tight; Mr. Neville's estimate for Ballysmutten was £218,000, and £30,000 for another reservoir; the next plan was one for the supply of water from the River Vartry, which, I believe, is the best in the neighbourhood of Dublin: my own impression is, that the two canal companies would yield a sufficient supply—viz., ten million gallons daily, but I do not think they could guarantee a preferential supply to that extent; the difficulties with which the corporation met in reference to these schemes are, I believe, the cause why they are represented here to-day.

Mr. Hawksley's examination was resumed. He first gave in the results of several analyses of water, made since 1854; also a report of Dr. Donovan in reference to spongilla. Said that spongilla were not peculiar to Dublin, and that they abounded in other places. They were, for instance, in the New River in London, and in several localities in that city, where he had seen some one inch and a-half in length. He understood that they extended down half a mile from the reservoir of this city, but he had not seen them himself at that distance. It was only of late years that they had made their appearance, and were first noticed about the same time as the American weed, but there was no accounting for them. It was uncertain, too, whether they should be ranked among vegetable or animal substances. Mr. Hawksley then handed in a communication from Mr. Hassard, dated 3rd September, 1858, in reference to the Vartry scheme, and alluded to the question of filtration. It had been stated during the enquiry that the cost of filtering would amount to £150 per million gallons, but what was not a fact. To his own knowledge the cost in some places in England did not exceed £40 per million gallons. He concluded his statement by saying that he believed the Corporation had done everything in their power to promote the interest of the citizens in regard to this matter.

Dr. Gray then handed in a letter from Dr. Corrigan to the effect—

"That our present supply is not of good quality—that it is not of sufficiently pure and wholesome character; has been for many years one of the physicians to the House of Industry Hospitals on the north side of Dublin, containing upwards of 300 patients, and the quality of the water has been a subject of complaint. On referring to the report books, finds the following entry:—

"'The water supplied to the Whitworth and Hardwicke Hospitals is heavily loaded with impurities, &c.

"'January 18, 1854.'

"This report was signed by all the physicians. Again, in September, 1854, the following:—

"'The physicians beg to draw the attention of the governor to the very impure state of the water supplied for hospital use—for drinking, dressing food, &c.'

"The water here referred to is from the canal, from the same level which supplies the basin at Blessington-street. It comes from a portion of the level which probably contains a greater portion of impurities than the portion supplying the basin; but the difference is only in degree, as whatever taint or impurity exists in one portion of the level necessarily spreads through the whole of it.

"A three-cylinder cast-iron filter has, since the date referred to, been erected on the hospital grounds, and the water has been improved to a certain extent—but only to a certain extent—for a filter will not make impure water pure water.

"I had no idea, until the water supply of the city was a subject of general discussion, of the extent to which popular misapprehension exists as to the nature and power of a filter. The best filterer that ever was constructed will not make impure water pure water, or convert unwholesome water into wholesome water. A filterer will never do any more, and can never do any more, than separate, in the passage through it, from the water such substances in the form of mud, sand, hairs, straw, &c., as may happen to be *mechanically mixed* with the water, but it will not separate any substance whatever, whether poisonous or wholesome, which is *dissolved* in the water. The distinction between *mechanical admixture* and *solution* must be clearly kept in mind. Any one may satisfy himself of this in an hour. Let him provide himself with four or five glass funnels, such as are used for chemical purposes, and place in each a filtering paper, which is far more perfect for its purpose than any filter that can ever be constructed on a large scale. Let him now take solutions of sugar, gum, salt, strychnia, arsenic, lead, and solutions of organic substances, the drainage of a dung pit, and the drainage of a knacker's yard; let all the solutions be muddied by the addition of clay, sand, flock of wool, paper, straw, &c., the various mixtures will pass through the several filters, and appear underneath as clear, or perfectly transparent fluids. All the mechanical admixtures will be stopped on one side of the filter, but the soluble matters, whether poisonous or wholesome, sugar or strychnia, salt or arsenic, the soluble organic portions of the blood from the slaughter yard, and of vegetable decomposition from the dung pit, will remain in the water, filter it as often and as carefully as you may. It must be then kept clearly in mind that filtering will not convert bad water into good water, it will only improve water so far as averting mere mechanical admixture, but that it will not remove poisonous or impure matters *dissolved* in the water. It will make muddy water clear, but clear water may be very unwholesome.

"The greatest attention is paid to the hospital filter already referred to. It is carefully cleansed, at least once a year, and fresh gravel and sand introduced. At each cleansing three or four stable buckets full of fine deposit are removed, and the deposit found to contain a large proportion of organic matter, not only on the near side of the filter, but also deposited after the water had passed through the first filter. This organic matter must have passed through the first filter in solution, and then undergone some change under which it became precipitated. Even ova will pass through the fine sand filter, for worms and various water insects of considerable size were found in the clear water receptacle after passage through two filters, which could only have become developed there from their small ova passing through. With such results from a small filter it cannot be expected, I think, that a better state of water, or equally good, would be obtained from a filter on a great scale. Professor Apjohn was kind enough to examine the deposits I allude to, and it is on his authority I state that the proportion of organic matter was considerable. It is now about two months since the filter was cleaned out, but it is not improbable that even after this short period a re-examination of it by Dr. Apjohn would afford some useful information.

"I can never think that the water of a canal used for traffic purposes should be also used for drinking, for preparation of food, beverages, &c. Whatever objections applied to the proposal of last year as to the water of the Liffey, or of any other river receiving into it impurities, apply with much greater force to the water of a canal. If there be very much traffic, then the admixture of impurities of all kinds from the banks, from boats carrying manure, coals, cattle, and minerals, from every boat being a dwellinghouse for boatmen, with the canal as their house drain, and from the boats, as I have been informed, not unfrequently containing permanent stabling for horses, must be in proportion to the amount of traffic, while on the other hand, if there be very little traffic, each level of the canal becomes a settling pool for the deposit and putrefaction of organic remains of animal and vegetable matter.

"It has been, I believe, advanced that, by taking the water from a higher level and from a more distant point on the canal, a purer quality of water would be obtained. I think this is true, but only in degree. It would be more correct to say a less impure water would be obtained, for the same causes of impurity, although not perhaps to the same extent, would operate at the highest level as those that exist near the city. Cattle and men are carried over the highest level as well as over the lowest. The manure that is received into boats at Dublin must be discharged somewhere else, and the same offensive consequences as to its drainage and its falling into and tainting the water when it is being loaded must equally occur when it is being discharged. The banks must be equally open all through for the admission of accidental impurities, drowned animals, &c., and, although somewhat less in degree, the highest level will be open to the same objections in principle as the lowest.

"Chemistry is a wonderful science, but in a question of this kind, with all our respect for it, we must not trust to it alone as a test of the unwholesomeness of water.

"A soda water manufacturer has informed me that soda water or effervescing lemonade made with the pipe water of Dublin, no matter how carefully filtered, will become foul in a few days. I would take this, if it be confirmed, as evidence of the unfitness of canal water for drinking purposes against all contrary opinions based on chemical analysis.

"Moreover, we ought to know clearly what chemistry can do and what it cannot do. Chemistry can tell us the amount of organic matter in water, but it can tell us nothing of the nature of that organic matter in reference to its being injurious or otherwise. Chemistry cannot tell us what is the difference between the air of a district where to breathe it is death from cholera or yellow fever, and the invigorating breeze of the most healthful mountain top. Chemistry cannot discover any essential difference between the poison of a rattlesnake and the white of an egg, nor between a poisonous and wholesome mushroom, a wholesome oyster and a poisonous mussel, nor between the saliva of a healthy dog and the poison of the rabid animal, nor between the purulent but harmless matter that is discharged from a whitlow and the poisoned matter of glanders, more certain and more dreadful in its action than the poison of the cobra. We should obtain from chemistry all the knowledge it can give us, and it can give us great knowledge; but we must not be altogether guided by it in the question before us.

"There is another circumstance connected with the admixture of any impurities with our drinking water which we must not overlook—viz., *slow* action, and this observation applies to all impurities, whether organic or mineral. On this point chemistry has given us great assistance. We have all heard of instances in which the health of the inmates of a house or of some large institution has been gradually deteriorating, until at length it has been discovered that the water has been acting slowly in a leaden cistern or pipe, and a process of *slow* lead poisoning has been going on. Those who are not familiar with such subjects will scarcely be prepared to believe the small quantity of poisonous material capable of producing injury, as well as the length of time through which they will exercise their slow poisoning, and consequent undermining of health.

"I saw a man in hospital who, on examination, presented the professionally well-known narrow blue line in his gums indicative of lead poisoning. For several days all questioning to discover any connexion between his occupation and lead failed. He was, he said, a paviour's labourer in the streets, but at length, in conversation alone with me, he confessed that pipes were being laid where he had been at work, and that for some trifling reward he had for a considerable time done the work of smearing with white stuff pieces of hemp, and introducing them into the joints. He was afraid at first to confess this, as he dreamed that he might be dismissed for going to other work than his own. The white stuff was white lead.

"In another instance a person in business in a country town presented symptoms of slow metallic poisoning. His trade was in the soft goods, and it was only after careful examination it came out that on each market day he spent one or two hours buying metal scraps from hawkers, and that it was part of the process to rub almost every piece of metal closely between his fingers to ascertain whether it was copper, lead, &c.

"In a third instance, a writing clerk fell into very bad health, which was of long duration. The symptoms of metallic poisoning were present. In this instance also it was only after careful inquiry it was ascertained that he wrote in an office over a basement storey in which stereotype casting was carried on. The ceiling was not plastered, and air impregnated with metallic vapour passed up through the open joints of the flooring. In these two last instances it took some years to break up the health irreparably, and in both death was the result.

"A few years since, from some interruption in the trade with Naples, sulphur rose very much in price. Sulphuric acid, which is so largely used in the arts as an internal medicine, and in making acidulated beverages, was then temporarily manufactured from pyrites, and the results might have been deleterious and slowly fatal; but, thanks to our active and intelligent chemists, they almost immediately discovered that this sulphuric acid contained arsenic.

"Very recently the solution of perchloride of iron, used as a disinfectant in London for sewage, has also (it has been discovered) been found to contain arsenic, and its use has been discontinued.

"Our knowledge of the slowly injurious effect of organic impurities and of their nature is as yet very imperfect; but we know quite enough to put us on our guard as well against them as against mineral poisons. We know that a very small quantity of impure animal food may be as certainly fatal to life as mineral poison, and we know that already the refuse fluid from the manufacture of straw paper destroys the fish in the streams into which it flows, as the metallic impregnations has destroyed them in the rivers of the county Wicklow. All these considerations, I think, lead us to the conclusion that we ought not to take our supply from canal water, which must ever be liable to all the injurious impregnations that are likely to arise from comparatively stagnant water, from the multifarious animal, vegetable, and mineral substances carried as articles of traffic, and from the canal itself being the receptacle for the sewage of every boat carrying live lumber.

"We have used canal water in part for our supply for many years, and the poor who could not obtain other for drinking, have been obliged to use it for drinking also; but I hope that circumstance will not be used as an argument for being satisfied to continue its use. It might, with as much reason, be argued that, because our people have lived for many years upon potatoes, and in mud cabins, that they should continue to do so.

"I believe a supply of wholesome, palatable water for drinking would have a powerful influence in promoting temperance, and I believe that the continued use of unpalatable and unwholesome water tends to maintain intemperance in our city, and to spread it throughout the country. Among our working people whiskey is had recourse to, to correct the mawkishness of our pipe water, and a similar effect is seen on a much larger scale in regard to the country. Our railroads now bring weekly on excursion trips, or on visits of short or long stay, thousands of our farming and business people to Dublin. My opportunities enable me to say that I hear among them one universal complaint of the 'nasty' pipe water of Dublin, and brandy or whiskey is added as a corrective, and very often by men and women, too, for the first time. The taste is acquired, the habit is established, and the hitherto temperate country liver returns home a dram-drinker, to injure himself by his habits and others by his example.

"We must, therefore, take into account, not only the purity of water, as tested by chemistry, but its gratefulness, as tested by the palate. I have seen it stated by some writers of high position, in the late water controversy, that they think the present water supplied to the city is very good drinking water, palatable, &c.; but it has been entertaining and instructive to me to ask some of those how often in the day do they taste the present pipe water, and how far is their palate, at the time, capable of appreciating it. Not at breakfast, when high-flavoured tea and broiled ham interfere. It is scarcely ever tasted at midday, when the hard-working man must drink it in large quantities to supply the waste of perspiration, just as solid food is taken to support muscular strength. Seltzer, or soda water, or beer, or wine and water at dinner is drunk, or plain water is taken with or after articles of food that leave the palate incapable of judging. In the evening the opportunities are not more favourable for palate testing. But, can we take our experience from the working people of our own city? I think not, for those who have been for years inhaling bad air and drinking bad water, are not competent to judge of pure air and water. But we can get the test we want in the judgment of the thousands of our country visiters; and this, without an exception as far as I know, is as I have stated above.

"I fear I must have tired you with this long letter, and you may now naturally ask me, if I find fault with the canal water, and have said nothing in defence of the Liffey scheme, as proposed last year—have I any other source to suggest? I have not; I am not competent to offer any suggestion; but I cannot think that, with granite mountain ranges within a few miles of our city, it would be difficult to obtain a supply of water that would be wholesome and palatable, and fit for our manufacturing purposes. In principle, I believe water collected on our granite peaks, or flowing over or through granite, would be well aerated, palatable for drinking, and free from hardness for our manufacturing purposes. I hope you will have the advantage of examining Mr. Jukes, professor of geology, and director of the geology of the ordnance survey of Ireland. I should attach very great value, indeed, to his opinions, for he possesses an intimate, scientific, and practical knowledge of every hill and valley round Dublin.

"I see in many continental cities, not half the size or wealth of Dublin, water brought, for purity sake, from very long distances—twenty, thirty, or forty miles—and I cannot think that we ought to be deterred, by even a very large difference of expense, from doing the like. The supply now adopted will probably be the supply for many successive generations; and as they will benefit equally with us, they ought to be satisfied, and they will be satisfied to bear with us the expense.

"I will ask your attention in conclusion, to one matter; perhaps it may be more properly considered as of detail in legislation. I think it was contemplated in a former bill to lay down water-pipes into every house inhabited by the working classes who occupy houses in tenements, and thus bring an ample supply of water within the reach of all. I fear this would never be practicable. Independantly of the many legal difficulties that would interfere to prevent the enforcement of any compulsion on the proprietors of such houses, there would remain this practical difficulty, that unless for all except the tenant of the room, cellar, or yard, to which the pipe was introduced, for the tenants of the other tenements could not have access to it. For these reasons I should be desirous of seeing numerous fountains erected in all our crowded localities inhabited by the poorer classes, with catch basins around them. From these the poor can never be excluded. I might enlarge more on the necessity for health and temperance, and comfort's sake of the benefits to our poor of an abundant and accessible supply of good and wholesome water; but you will have, I assume, the assistance and opinions of Mr. Willis, of Ormond-quay, who devoted very much time and attention to the sanitary state of the district around him, and more particularly to its connexion with water supply.—I am, my dear sir, very truly yours,

"To Dr. Gray." "D. J. CORRIGAN.

Mr. Bateman then referred to some observations which Mr. Hawksley made in his statement, with reference to the Marquis of Downshire's opposition to the reservoir proposed in the plan of taking water from the Upper Liffey. He had reason to know that the only reason why his lordship objected to the plan was, that it would tend to make marshy a portion of his estate which at present was a rich pasture land.

The Commissioner inquired whether he believed the Marquis of of Downshire would oppose the construction of a compensating reservoir on his estate, in case the Corporation would pay the millers in water compensation, and not in money?

Mr. Bateman said thought his lordship would have no objection to its construction. Mr. Bateman then referred to Mr. Hawksley's views and calculations in relation to the fall of rain in the district from which the water was proposed to be taken from the Liffey. He said that Mr. Hawksley's calculation of allowing 2½ per cent. for every hundred feet of rise was altogether erroneous, and should not be acted on. He then referred to the numerous returns in England, Scotland, and elsewhere, to show that the actual fall of rain was very different in these places to what it would be according to Mr. Hawksley's calculations. He also dissented from that gentleman's views in relation to the expense of filtration, which he considered would be considerably greater than he proposed.

Mr. Mallett said he remarked with some surprise that Mr. Hawksley had departed somewhat from his original *data* by assuming the supply to be for 400,000 people, whereas the population of the city and suburbs was only about 270,000. He (Mr. Mallett) was also in a position to give some precise information as to the quantity of water required for manufacturing purposes, for he had been connected in the way of business with several breweries and distilleries. In Mr. Darcy's brewery, for instance, the supply of water, and which was obtained from the streets, was only about 18,000 gals. daily, and judging from that and other establishments, he would say that, supposing there were ten such in the city, the supply of water required from the streets by them would not exceed 150,000 gals. daily.

Mr. Halpin, on the part of the Ballast Board, said that when the tide was out a large portion of the Liffey was left dry, and many complaints had been made of the offensive state of the bed of the river on such occasions. Something had been done to remedy the evil by cleansing the bed of the river from time to time; in his opinion if ten million gallons of water were abstracted from the Liffey, it would be in a much more unhealthy condition than now; he was not aware that the Ballast Board had any objection to the abstraction of water from the Dodder, but they had an objection to any injurious abstraction of water from the Liffey.

The Commissioner—If a large reservoir were constructed, would the objection of the Ballast Board be removed?

Mr. Halpin replied that, if made sufficiently large, he thought it would, especially if the water which was taken out to be used by millers was returned to the river again. The Ballast Board would, however, object to any withdrawal of water which tended to injure the river or harbour.

The Commissioner inquired whether there was any difficulty experienced at the entrance of the harbour?

Mr. Halpin said the bar had been gradually improving for several years, and that there was no apprehensions entertained as to injury being done to the harbour by the withdrawal of water from the Liffey. The injury apprehended would occur above the mouth of the river, if it occurred at all.

Mr. Hawksley said there was some misapprehension on the part of the Ballast Board as to what the corporation proposed to do, or, in fact, what had been proposed in the several schemes referred to. What the Admiralty always objected to was, the impounding of the floods, but they did not propose to do anything of the sort. As regarded the Ballysmutten scheme, it would be found that all the water taken from the Liffey would return into it again before it reached the city. Mr. Hawksley then alluded to Mr. Mallet's statement in regard to the population of the city. According to the last census which was taken in 1851, there were 285,986 people in the city, and in the limits to which they proposed to extend the water supply there were 64,000 more, making a total population of 85,000. He said there was also some misapprehension in regard to the quantity of water used in the city for manufacturing purposes, which was much greater than Mr. Mallet supposed.

Mr. Brassell was then briefly examined touching his scheme, known as the Poolaphooca one. He said it was unnecessary to go into the details of it, as the commissioner was already in possession of them, but he wished to state that the district to which he referred had not been sufficiently examined; also, that it would be absolutely necessary to store the water in order to secure a regular supply. In support of this statement he referred to the history of Limerick, to show that even the river Shannon had been known to be quite dry. This occurred in the years 1666, 1698, and 1723.

Mr. Whelan, T.C., then read a long statement, giving his views upon the water question, which, he said, as a member of the corporation, he felt bound to do. He denied the capacity of either the Liffey or canals to supply the city with pure water, and advocated the taking of it from the lakes in Westmeath.

The Lord Mayor said, in reference to Mr. Whelan's statement, that if he came forward as a member of the corporation to give his views, he wished it to be understood that Mr. Whelan had done so without the sanction of the corporation, and solely on his own responsibility.

Mr. Mulvany said that there was some misapprehension in regard to the traffic on the canal, to which reference had been made during the inquiry. Although the passenger traffic had quite ceased, the goods traffic had increased of late years. As regarded the nuisance which, it was said, the boatmen threw into the canal, he believed a very erroneous impression had been made. The boatmen did not injure the purity of the water as represented.

Mr. M'Mullen said his acquaintance with the canal was much longer than that of Mr. Mulvany, and that from returns made to him he knew that the number of boats had been greater in former years than at present.

Mr. Hawksley said, in reply to some of Mr. Bateman's statements, that he had misrepresented his system as to the manner in which he calculated the fall of rain. He meant that his calculations should be acted on when a place could be found near the water side; but he never dreamt that they should be taken at a great distance from it. As regarded filtration, he believed that it would be found necessary, no matter what water might be selected.

The business being now concluded,

The Lord Mayor rose and said—This inquiry having now concluded, it is my pleasing duty, on the part of the corporation, and on my own part, as chief magistrate of the city, to thank you, Mr. Commissioner Hawkshaw, for the great urbanity and attention you have paid to every person who has been connected with this inquiry. It is a remarkable fact, and one not always found in our meetings, that during the whole investigation not one angry word has been uttered, which I can only attribute to your urbanity, as well as the ability and zeal which you have displayed in the discharge of your duty. I feel confident that, from the position you have attained in your eminent profession, the corporation and citizens of Dublin will turn your ability to the best advantage, and adopt whatever report you may think fit to make.

The Commissioner, in reply, thanked his lordship, and said he hoped that the corporation would soon see their wishes accomplished, by the completion of a work which would be worthy of the city, and which should be regarded as one of the most important in connection with it.

Alderman Hudson called attention to the necessity for publishing all the useful information which had been elicited during the inquiry.

Reviews.

Wilme's Handbook for Mapping, Engineering, and Architectural Drawing (Re-issue). London: John Weale.

A HURRIED glance at a book on the eve of going to press would neither justify a critique upon its merits, nor be fair play to the author; but of this before us—while in courtesy acknowledging its receipt at the eleventh hour—we remark, *en passant*, that it brings with it two *facts*—as *prima facie* evidence of its value and consideration for a reviewer—the one, that the extraordinary demand for the first edition exhausting every available copy in a twinkling, necessitated a *re-issue*; the other, that its identification with the name of "John Weale," a publisher in the architectural, engineering, and scientific world of universal renown, affords a guarantee that there must be some attractive metal in its composition. However, we shall revert to it in next number, when time shall have afforded opportunity for fuller consideration in detail.

Miscellaneous.

SUCCESSFUL APPLICATION OF STEAM CARRIAGES TO COMMON ROADS.—Recently the Earl of Caithness started from Inverness in his steam carriage, built under his own direction, and reached Beauly, a distance of 14 miles, in an hour and twenty minutes—notwithstanding the frequent stoppages, and fifteen minutes lost in getting water—without any more inconvenience to the general traffic or alarm to horses than if he had been in his carriage and four. So perfectly had he the whole moving power under his control, that he stopped more quickly than an ordinary carriage and horses could draw up, and this he did as often as he saw the least danger of any horses being frightened. After leaving Beauly, on those parts of the road where some distance forward can be seen, he attained the speed of eighteen miles an hour, and could have kept this up for any distance with ease and safety. On the road direct from Bonar-bridge the carriage had a severe test applied to it, but he drove it up the hills without difficulty, and coming down the steep declivity near where the road joins that from Tain, the control his lordship had over it was most satisfactory, and enabled him to descend at any rate he wished, and with perfect ease and safety.—*Banffshire Journal.*

A Liberal Insurance Company.—It is a fact worthy of being recorded, and which should be appreciated substantially by those who have occasion to effect fire insurance policies, that in the case of a recent fire at Alderman Mullen's warehouse, Victoria-street, Belfast, the sum of £900 was promptly paid by the Imperial Insurance Company, although virtually the policy had lapsed, owing to the nonpayment of the premium within the stipulated period. Were the company disposed to avail itself of a quibble, the law would undoubtedly have protected it; but generously assuming that the lapsing of the policy resulted from inadvertence, the customary notice having been omitted to be forwarded, the company admitted it to be in force, and paid the amount previously insured for.

The Shilling Art Union.—Mr. M. Angelo Hayes's picture of the Charge of the 3rd Light Dragoons at Moodkee has been selected, by Messrs. Bianconi and M'Swiney, for the £100 prize won by Mr. Broderick. A smart correspondence upon the alleged exclusion of Mr. Hayes's pictures from the exhibition of the Royal Hibernian Academy, has followed between Mr. M'Swiney and the President of that body, Mr. Catterson Smith. Several prizes are still unclaimed, and we are informed that the advertised numbers of prize tickets in the local journals do not correspond with the committee's special report. If this be the case, the probability is, that the prizes may *never* be claimed—the holders of tickets, relying on the accuracy of the advertised numbers, having destroyed their tickets when compared therewith, finding that they were not prizes. To say the least, a mistake of this kind would be unfortunate, and ought to be guarded against previous to the announcement of next year's drawing, by a careful comparison of "proofs" with the registered numbers.

The Boyne Viaduct.—In the recent report of the Directors of the Dublin and Belfast Junction Railway occurs the fellowing paragraph:—"Since the last meeting Mr. Hawkshaw had twice inspected the Boyne viaduct, and had confirmed the assurance he had given the directors on a former occasion—'that the structure was safe, and that all apprehensions of insecurity on the part of the public were unnecessary.' Mr. Barton, the company's engineer, had been directed to make the necessary preparations to carry out certain works recommended by Mr. Hawkshaw." Personal visits of ourselves to this structure would confirm Mr. Hawkshaw's statement, for there is no apparent cause of any instability whatever. The pier in question is most awkardly placed for the free navigation of the river, and there is a strong feeling prevalent in the town that the railway should not have crossed at that point, but more northward.

Autographic Telegraph.—At the Sardinian Exhibition there is a novelty which attracts much attention—the model of the autographic telegraph, an invention of Signor Bonelli, the director of the Sardinian telegraphs. In a small machine that stands on one side of the room you insert a slip of prepared paper, which looks as if it were silvered, and on which you have written a sentence. This machine communicates by an electric wire with another machine of similar appearance at the other end of the room. Between two small rollers of the latter machine you insert a slip of yellow paper, which passes through the rollers, receiving in its passage a green stripe down its centre, on which appears, in black, the exact *fac-simile* of the writing on the paper put in at the other end. The transmission is only across a room; but it is presumable and the inventor is confident that it might be made with equal ease and correctness across a continent or under an ocean, the wires once laid down. The marvel is effected by a combination of chemistry and electricity. Should no practical objections be found to the adoption of the system, this will be, as far as correctness goes, the very perfection of telegraphic transmission.

The Telegraph System.—There are in England four lines of electric or magnetic telegraphs, namely—the Electric and International Line, the British and Irish Magnetic, the South-Eastern Raiway Line, and the London, Brighton, and South Coast Railway Line. The first of these lines extends over a distance of 6,103 miles; the second, of 3,656 miles; the third, of 308 miles; and the fourth, of 119 miles; making the total length of all the lines 10,186 miles. The length of the wires used in all these lines amounted in the year 1858 to 48,990 miles; the number of stations opened for the public was 953; and the number of instruments was 4,065. In 1856 the number of messages sent was 125,622; in 1857, 1,237,013; and in 1858, 1,321,086. On the 1st of January, 1859, the Electric and International Company had 85 agreements with railway companies and public offices for their business messages. The number of such messages is estimated to amount to three times the number sent by the general public. This company also furnished intelligence, on the 1st January, 1856, to 180 provincial newspapers, and to 70 different reading rooms. The number of messages to and from the Continent, transmitted jointly by the British and Irish Magnetic and the Submarine Telegraph companies, and the number of messages for railway companies, newspapers, and newsrooms, are estimated at about 250,000 messages per annum.

Pope's Villa.—All that remains of Pope, at Twickenham, is his grave, his grotto, and his reputation. The "Tusculum" which he built out of the profits of his "Homer"—it is a profound mystery how authors *could* have been paid so well in those remote times—was pulled down by a sensible lady, who did not like an inconvenient house, even though the inconvenience might be due to the whims of a great poet. The grotto, which formed the entrance to the garden, has been suffered to remain, and a new house has been built close beside it. This modern erection will attract the notice, if not the admiration, of every stroller on the banks of the Thames. Its style is composite, and indefinite; and if I were to apportion even a small part of it to any known order of architecture, I feel that I should utterly forfeit the confidence of the reader. It displays a luxury of carving and colour not often—happily—to be witnessed in this country. If you are a bold man you may take a picture of it: there is ample space on the opposite bank to place your camera, but I cannot attempt to predict the result. The village of Twickenham contains some old-fashioned houses, and some streets of those peculiar, shabby genteel villas, with stone fronts and brick behinds, and exactly twelve square yards of garden each, which are the outward expression of the spirit of vain show pervading modern English society. The village also contains a number of public-houses, one church, and numerous fancy shops. For the rest it has nearly, though not entirely, lost its literary reputation—one or two names not unknown to literature and science are still to be found among its inhabitants.—*Photographic News.*

Fishamble-street Theatre in 1741.—About this period, Handel, for the first time in Dublin, produced his well-known "Messiah", and Fishamble-street Theatre being the "Musick Hall" was selected for the performance of the oratorio, at which gentlemen of the choirs of both cathedrals assisted, and the great composer played some concertos on the organ. The following paragraph, quoted from the advertisement, as published in *Faulkner's Journal*, will be found singularly *apropos* to certain expansive fashions of the present day. N.B.—"Many ladies and gentlemen who are well-wishers to this grand charity, for which this oratorio was composed, request it as a favour, that the ladies who honour this performance with their presence would be pleased to come without hoops, as it will greatly increase the charity by making room for more company." There can be no doubt but that the Hall was crowded every time this oratorio was performed, and that the fashions of the period bothered the managers exceedingly; for, on a subsequent occasion, we find that the ladies are again entreated on the subject, and informed that, if they "lay aside their hoops for one evening, the hall will contain an hundred persons more, with full ease." The experience of 120 years back may perhaps be found available for present instruction.

INSOLVENT BUILDER.

Aaron Loughnan, of Townsend-street, Dublin.

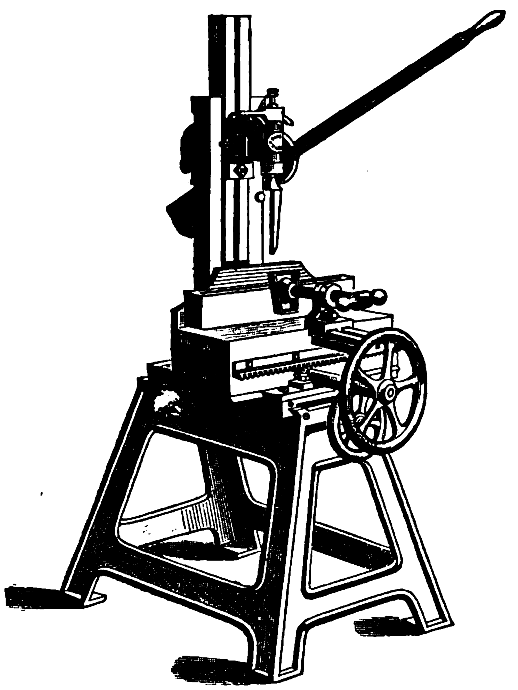
Acknowledgment.—Apropos to the courtesy extended by certain railway companies towards the editor of the Dublin Builder, in the granting of free passes on their lines, we desire to record in an especial manner the recent favours of the London and North Western Railway and City of Dublin Steam Packet Companies respectively, by means of which we are enabled in this and subsequent numbers to present our readers with some additionally interesting intelligence.

Notice.—We publish herewith a supplemental inner sheet of 8 pages that our reading space should not be encroached on by the increased number of advertisements; as also that we might present a detailed report of the recent proceedings at the commission of enquiry respecting the water supply of this city.

Note.—We are requested to mention that the name of the Clerk of Works at SS. Peter and Paul's Church, Cork, is "T. Langford Ely," not "Langford," as stated in the description of that building at page 310.

[*Advertisement.*]

Trade Catalogues.—One cannot but be struck with astonishment at the innumerable ways in which an enterprising tradesman appeals to the public with a view to increase his trade. Printing in all its branches, assisted by the skill of the wood engraver, seems in the present day to be one of the media most generally employed in spreading the knowledge of various manufactures. These arts have ably been brought into use by Mr. Benson, the eminent watchmaker of Ludgate-hill, who has sought by means of an "Illustrated Pamphlet" (consisting of nearly 60 pp., and containing upwards of 250 beautiful designs for watches, clocks, &c., with an elaborate description of every construction of watch now made), to enable persons living in any part of the world to select the watch best adapted for their use, and have it forwarded free by post.—*Sun*, 23rd August.



WILLIAM BISSELL,

UNION-STREET,

WOLVERHAMPTON,

SOLE Proprietor of the Improved MORTISING MACHINE, the newest, most easy, simple, and powerful yet invented. To be seen at work at Messrs. Timothy Murphy & Son, Builders, Amien-st. Dublin.

Also the universally and justly-celebrated Equi-action RIM AND MORTISE LOCKS.

Patentee of the well-known FLOORING DOGS, AND 4-TON LIFTING JACKS.

FACTOR

AND

General Manufacturer

OF

BUILDERS' IRONMONGERY.

NEW HOUSE-FURNISHING WAREHOUSE.

JOHN W. CARROLL (formerly Manager to Messrs. Wm. Fry and Co.),
27, GRAFTON-STREET, DUBLIN,

Wishes to direct attention to his present Stock of

CURTAIN MATERIALS.

Just Received, all the Leading Patterns in the

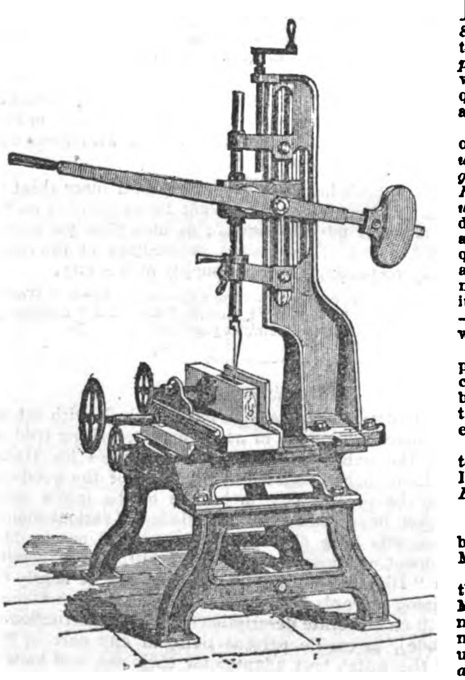
NEW BELGIAN DIMITIES, &c.,

SWISS EMBROIDERED LACE MUSLIN AND LENO CURTAINS *(Duty Free)*.

Estimates and designs free of charge. Pattern Books forwarded on application.

GALLON AND BEAN, LEEDS,

Cut & Wrought Nail Manufacturers, & Hardware Merchants,



RESPECTFULLY request all BUILDERS, CONTRACTORS, CARPENTERS, &c., requiring Mortising Machines, previous to purchasing, to examine and test *their patent combined Crank and Lever Machine*, which will Mortise (Tenon and Bore, if required) both Hard and Soft Wood, and is also adapted for Drilling and Punching Iron.

The superiority of this Machine over *all* others consists *in the substitution of a solid wrought-iron plate Crank or Eccentric, by which greater power is obtained, in place of cast-metal Rack and Pinion Wheel, the Teeth or Cogs in which are so liable to strip or break out*—in the direct and perpendicular action of the Lever and Crank on the Cutting Tool, and consequent diminution of friction--in being *stronger* and *less complicated* in its construction, and more *powerful* in its motion—in the *facility* of its *adaptation* to the various depths of material —and in its *non-liability to break* or get out of working order.

This Machine has now been adopted in preference to *all others* by some of the principal Builders in London, Glasgow, Edinburgh, Dublin, and Belfast, who will bear testimony to its being the most powerful and efficient yet made.

For further particulars apply to the Patentees and Makers, GALLON, BEAN, and LUMB, LEEDS.

Extract from the Report of the Royal Dublin Society's Spring Show, 1859:—

"Gallon, Bean, and Lumb, Leeds, exhibited a very useful and complete Mortising Machine, which was highly commended."

N.B.—The Patentees respectfully intimate that this Patent extends to, and comprises Machines for Mortising by Steam and other motive power, as well as by hand; and makers and vendors of, or parties buying or using Mortising Machines, *are cautioned against any infringement*, as the patent right will be strictly maintained.

Building Ground, &c.

CAPITALISTS, BUILDERS, or Persons desiring peculiarly advantageous Residences in the vicinity of Dublin, are invited to view

THE LAKELANDS OF TERENURE BUILDING ESTATE

(Two miles from the City),

which presents a combination of advantages for Dwelling-houses not to be surpassed, if equalled, within the same distance of any capital in the empire.

These advantages are—salubrity of atmosphere (the land lying 200 feet higher than Merrion-square, and within the current of mountain air), abundance of the purest soft and spring water, a gravelly soil, singularly beautiful pleasure grounds and prospects, bathing, fishing, and boating on the Lake, which is larger and more beautiful than that at the Crystal Palace.

ONE HUNDRED BUILDING SITES

of this Freehold Property, having a Frontage of about 3,000 feet—1,500 facing the beautiful Lake of Terenure, with its wooded islands, a Deer Park on the opposite side, and mountains in the distance; and 1,500 facing a noble carriage-drive, lined with stately trees, and nearly a mile in length, are now to be let.

The Tenants will enjoy free ingress, egress, and regress to the beautiful shrubbery walks and use of the Lake, which, containing altogether about eight acres, will be carefully conserved.

Application to be made to S. D. DOUGAL, Esq., Civil Engineer, Surveyor, and Architect, 27, Lower Pembroke-street, Dublin, who alone has authority to show and let the Estate.

Mr. Dougal would undertake to Build Houses for private persons at wholesale prices, which would enable parties commanding even small capital to become the owners of Freehold Houses for one half the usual rents.

BELMYRA, DUNDRUM, CO. DUBLIN.

TO CAPITALISTS, BUILDERS, & OTHERS.

MOST DESIRABLE BUILDING GROUND TO BE LET.—This Estate, containing 150 Acres, situated within half a mile of the Dundrum Railway Station, has been laid out in Lots for Building. The position is admitted to be the most beautiful in the environs of Dublin, and is particularly well circumstanced in every respect, commanding views of Killiney Hill, overlooking Mount Merrion, City and Bay of Dublin, &c.

A railway station in the centre of the estate is in contemplation, bringing it within ten minutes' drive per rail of Harcourt-street.

A map of the lands, showing them laid out in building lots, can be seen, and every information obtained, at the offices of Edward Henry Carson, C.E., Architect, &c., 25, Harcourt-street.

THE NEW BUILDING GROUND at RATHGAR, to be called KENSINGTON-SQUARE, is now ready for setting. Lease, 900 years. Several lots are already let. Plan and particulars at

BENTLEY & SON'S,
110, GRAFTON-STREET.

N.B.—A few lots for Cottages in KENILWORTH-AVENUE, adjoining the above.

TO CAPITALISTS AND BUILDERS.

TO BE LET for BUILDING, the Ground round Wellington-square and in Hatch-street, the Maps and particulars of which may be seen at the Offices of JOHN LOUCH, Esq., Architect, &c., 15, Molesworth-street, Dublin.

PURE AND BRILLIANT GAS LIGHT.

GAS IN COUNTRY MANSIONS.

IMPROVED PATENT HYDRO-CARBON GAS APPARATUS.

JOSHUA EDMUNDSON and Co. having the exclusive right to Manufacture and Sell this Gas Apparatus, call attention of the Public to this most valuable invention. It is peculiarly adapted for Lighting Gentlemen's Mansions, Colleges, Mills, Manufactories, Railway Stations, other Country Establishments, and Public Gas Works for Towns.

The Apparatus will produce more Gas from a ton of Coal than any other, and can be so arranged in the erection that the Cooking of an establishment, of whatever size, can be effected without expense, no fuel being required beyond that used in making the Gas.

Particulars as to price, size, scientific merit, etc., and the most satisfactory reference to parties for whom it has been erected in this country, will be given by

JOSHUA EDMUNDSON AND CO.,
34, 35, 36, CAPEL-STREET.

Estimates for all parts of the Kingdom given, free of expense.

Country Towns lighted at a very small cost.

Agents for Milner's Fireproof Safes.

The Dublin Builder.

VOL. II.—No. 22.

INSECURE SCAFFOLDINGS.

IF there be any truth in the saying, that "out of evil cometh good," it has had more than ample time to be developed since the recent fatal accident in Baggot-street, whereby, as already known to our readers, two workmen and a passer-by were almost instantaneously hurried into eternity, and verifying the text that "in the midst of life we are in death." Notwithstanding, however, the severe lesson so taught, no new leaf has been turned over, no practical steps to prevent, or at least diminish, the chances of a recurrence in future, have been taken by those on whose heads the responsibility rests.

The victims of negligence or ignorance—the one as culpable as the other when human life is in question—are cold in their graves; a coroner's inquiry, a few exclamations of horror and sympathy for the families of the deceased, an appeal and subscription, resulted from the accident, but as yet this is all!

Almost simultaneously—"for misfortunes never come alone," and if we hear of one accident there is pretty sure to be another in its wake—were there *two* providentially narrow escapes from fatal consequences at other establishments in progress in the city, owing to "insecure scaffoldings;" yet, with these, hosts of others preceding, and the sad one in question before our eyes, matters still remain as before in *statu quo*. How reprehensible! but so it appears likely to be till *another* and *another* coroner's jury arrive at the conclusion as in the case of Duggan, that "*the authorities having control, should not permit a thoroughfare under exclusive works of this kind, and we are further of opinion that the deceased might have escaped, if such precautions had been taken*," and till more lives are sacrificed, and families plunged into affliction and distress.

Will not our corporation interfere? and if not, why not? Prior to building operations in the city, if external scaffolding be necessary, it is required that a license be obtained, and a sum deposited at the City Hall; may we then ask if the corporation go *so* far, why do they not appoint a proper officer in connection with that department, to see that said scaffoldings are properly paled and constructed with due regard to individual and public safety? We may be met with the reply, that it is the builder's business to do it, or the architect's, to see it done; that may be very well in theory, but how does it result in practice? There were both an architect and builder directing the works at Baggot-street, at Sackville-street, and Parliament-street, yet the mishaps occurred, and on whom was the responsibility fastened? If it were the business of a salaried corporate officer to inspect these scaffoldings, and to see that they were carefully constructed, so as to lessen at least the *probable* chances of an accident, some security would be guaranteed, and in the event of a mishap arising from culpability, "the saddle would be put on the right horse." If a shop front project beyond its limit, if an area grating be dangerous, or a structure dilapidated, the City Surveyor has the remedy in his hands; it is not then too much to expect in the important matter of scaffolding, where both the lives of the workmen engaged thereon, and the pedestrians underneath are jeopardized, that the Corporation would adopt some measures of precaution, and *promptly*. Justice to the citizens and humanity towards our fellows, demand that it should be so.

Travelling somewhat outside the shadow of our adopted title, we may briefly—and perhaps not altogether inconsistently—refer to the late occurrence at the Portobello Gardens, where want of skill or proper precaution,—as the case may have been,—in the erection of scaffolding poles, caused the death of two poor men, employees at that place of amusement. The results were somewhat similar in this case to those above related, but save in the substantial sympathy of the public with the relatives of the deceased, no "universal good" has accrued from "the partial evil" thus inflicted. Probably we may incur the censure of sight-seers and pleasure-hunters for being too critical, if we proclaim such exhibitions to be highly reprehensible, nevertheless, at the risk of such disapprobation, we must express our conviction that the authorities ought not to permit them. Within the precincts of the city we believe the Lord Mayor enjoys a certain power to repress all exhibitions of a dangerous tendency, and we presume that outside its boundary a higher functionary is also privileged.

All achievements in science have been invariably attended during preliminary experiments with a certain amount of risk and occasional loss of life; but however that may be deplored, individually it becomes a positive necessity for the general weal; and a consolation is afforded, if the public of the age or posterity derive a benefit from such casualties. But in what degree towards the developement of any scientific end do "tight" or "wire" rope dancing conduce? Is a Blondin—be he the veritable or the assumed—or a Duvalli to be spoken of in the same breath with a Stephenson, a Fairbairn, or a Brunel. If Professor Lowe succeed in achieving by his monster aerial machine what he represents to be practicable, there may possibly come to pass a wonderful revolution in the means of transit both of passengers and merchandise, and steam on land or water be completely superseded. We might then become reconciled on principle, even to the previous sacrifice of human life in aeronautical experiments, and be convinced that sometimes "*out of evil*" *good cometh.*

RESTORATION OF ST. PATRICK'S CATHEDRAL.

A CORRESPONDENT of *Saunders's Newsletter*, of 29th ult., with reference to this cathedral, says:—"When the present works of restoration were commenced, at the cost and under the direction of Mr. Guinness, there remained but little of the cathedral that was not either ruinous, or had been incorrectly and inharmoniously renewed. The north transept was entirely modern; much of the south cross end was scarcely more than half a century old. The eastern chapel had been not long since rebuilt, we cannot say restored. The west front, and the east end of the church had both been disfigured by pretended restorations, in which many distinctive features were obliterated. In the choir aisles, both north and south, and in the north aisle of the nave, the handsome mullioned windows of the fourteenth century had been most unnecessarily removed, and were replaced by simple lancet lights, which had not even the merit to which they laid claim, of agreeing either in figure or in position with the originals. In fact, the true principles of restoration had been everywhere violated, and a capricious as well as tasteless spirit of architectural pedantry was manifest in all the reparations. Hence the eastern gable is deformed by two huge misshapen pinnacles which, like asses' ears, project upwards at its base. Hence the incongruous figures of the pinnacles that crown the south-eastern and north-eastern flying buttresses, which are inconsistent and irreconcileable with the other buttresses, and with the general style of the building. The same want of taste is shown in the tiled flooring of the choir, which represents no ancient pattern, but is such a design as might have been drawn from a patchwork quilt by a washerwoman. Yet the ancient tiles, of various appropriate patterns, could be found in many parts of the church, and many of them had already figured in the work of Mr. Oldham, which is deservedly esteemed. St. Patrick's, then, furnishes in its former 'restorations,' as they have been untruly designated, an ample variety of examples to be avoided. . . . . . . At Armagh, the present Lord Primate has expended above £80,000 on the repairs of his cathedral, but it is complained that the architect 'perpetrated every form of monstrous absurdity.' In Dublin, Christ Church has been irreparably defaced, and St. Patrick's has also suffered much, though not to the same extent.

"Mr. Guinness had from the first determined that his should be truly a restoration, and that he would allow no deviation whatever. He has taken care to preserve an accurate record of every part that had to be removed. Drawing, admeasurement, and photography have all been employed, and every original fragment that could supply a pattern or a hint for one has been carefully sought out and followed. How faithfully this plan of true, honest restoration, free from all false mediævalism, has been followed, will be apparent to any person who will carefully examine the progress already made, which is far from inconsiderable. In particular, we would refer to the exterior of the choir clerestory on the south side, and its three flying buttresses. These, so far as they have yet proceeded, and the corbelling of the same side, may be contrasted with the contiguous unfaithful restoration, as it was called, of the east end of the church. The critical observer, if he has not a distinct recollection of the building previous to its reparations, should compare it with some good delineation, either in print or drawing. There is no exgraved representation at all comparable to the views taken by that excellent artist, James Malton, in 1793, which effectually disprove the pretended restorations of the east and west ends of this cathedral. Yet, scrupulously as Mr. Guinness has adhered to the principle of a correct and undeviating adherence to his model, he has not escaped from misrepresentation. A would-be critic, under the signature 'Mediævalist,' prompted by we know not what motive, has recently in a very acrimonious and abusive manner assailed both Mr. Guinness and the Dean and Chapter of St. Patrick's, not through the medium of any Dublin paper, but in *The Builder*, a well known scientific journal, published in London. In this city there is an excellent professional periodical, the DUBLIN BUILDER, a monthly publication, which would have been the legitimate channel for any criticism to which the works at St. Patrick's might appear fairly liable. But if it had been adopted, any misrepresentation would have been immediately detected by its readers, while in London a groundless statement as to a Dublin matter might be circulated very widely, and produce a most mischievous effect before it could be counteracted by a refutation. The 'Mediævalist's' letter is indebted solely to the respectability of the journal on which it has been imposed for any notice it may obtain, and to which otherwise it could not, even for its malicious cleverness, have the slightest claim. The 'Mediævalist' puts forward a number of charges, which would be overwhelming if they were only true; but the little truth that is contained in his letter does not support his argument, or rather makes against it; while to his direct misstatements and insinuations, it bears about the same proportion as Sir John Falstaff's pennyworth of bread to all that intolerable deal of sack. He commenced by desiring to call public attention to what he elegantly terms 'the present doings in St. Patrick's.' 'The matter from beginning to end has been done in a corner. Mr. Guinness first privately announced his intention to restore the nave.' This is a most absurd complaint. Mr. Guinness announced his intended benefaction in a courteous, respectful letter to the Dean and Chapter, by whom it was gratefully accepted. His critic appears to think the offer should have been made ostentatiously in a newspaper. The next charge is at once absurd and untrue. It carries its refutation with it. It is, that Mr. Guinness 'required the greatest secresy on the part of a few of those in office; so much, that although at the time the work of restoration was actually in progress, those who had charge of the building, I believe, were not informed of it for a considerable time.' What must be the 'Mediævalist's' reliance on English credulity when he expects the readers of the *Builder* to believe the works of restoration sanctioned by the Dean and Chapter could have been 'actually in progress' without the sexton, beadle, and verger, 'those who had charge of the building,' being informed of the matter? But not satisfied with this arraignment of Mr. Guinness, the 'Mediævalist' proceeds to 'question the conduct of the Dean and Chapter,' . . . . 'they, and not Mr. G., are the parties answerable for what has been done; and, in my opinion,' says the 'Mediævalist,' rising to a climax, 'they have been guilty of a gross breach of trust.' This is certainly a serious accusation. But has it the slightest foundation? Is the 'Mediævalist's' wrath to develope itself into a *quo warranto* procedure against the Dean and Chapter for handing over a portion of their church to Mr. Guinness for restoration? The next blows are aimed at Mr. Guinness. 'The letter written to Mr. Guinness, containing the terms of his agreement to restore the nave at his own expense, is a curiosity in its way.' Here the critic unintentionally gives expression to a truth—an offer of unprecedented munificence may not improperly be termed 'a curiosity in its way.' From the confidence with which 'Mediævalist' pronounces his opinion, it might be supposed that he had the letter before him, but in his next sentence he dispels that delusion. 'I am informed,' he says, 'on good authority, that Mr. Guinness merely says, that he will restore the south wall of the nave,' &c. Next he accuses the Dean and Chapter of an 'overweening confidence' in Mr. Guinness, to which it should not be supposed that his offer of defraying all the cost of the restoration could any way have entitled him. A series of charges against Mr. Guinness next succeeds. 'First, he refuses to have anything to say to those who have been engaged for many years in the restoration of the Cathedral. Next he shuts up the place, and will allow no one to enter to see the works.' It is true that Mr. Guinness refuses to employ any of those who have been employed in what they call the restorations during many previous years. Besides his unquestionable right to employ whom he pleases at this great work, he has a sufficient justification, if any were required, at the deviations exhibited in the former works, and of which Malton's views and others of more recent date furnish undeniable evidence. The builder employed by Mr. Guinness (one of a firm that includes an architect and builder) receives the next blow, for 'proposing to erect flying buttresses to an early English wall, after the pattern of some *debased* works at the east end of the choir.' Here is an important admission; the east end has been *debased*, under the pretence of restoration'; yet in his next sentence the 'Mediævalist' proceeds to blame the builder for refusing to adopt plans prepared some years ago, and which would have extended innovation and debasement to parts of the church that have hitherto escaped. Yet he admits also that those plans 'were not in accordance with the the Irish tradition;' the meaning of which is, that they disregarded the peculiarities of the Gothic architecture in Ireland, as shown in most of our ecclesiastical edifices, as well as in this Cathedral. Nor is it true that the *debased* that he mentions are now to be taken as a pattern. The shafts and pinnacles of the flying buttresses are to be strictly restored in exact accordance with the originals, but in a better and more durable material, the limestone of Tullamore. It is also untrue that no one is allowed to enter and see the works. On the contrary, there is unusual facility permitted for visiting and inspecting every part. The works are necessarily enclosed by a boarded fence, and there is put up a notice usual at all buildings, 'No admittance except on business;' but this is construed most leniently, so that even the 'Mediævalist' may if he pleased have explored the entire of the Cathedral six days in every week since the works commenced. We do not profess to know what he means by 'an early English wall,' nor how a mere wall, independent of arches, mouldings, copings, or other members could be designated as belonging to any order, but we can assure 'Mediævalist' that he is entirely wrong in his statement that 'the south wall of the nave has been already taken down in such haste that no drawings whatever could have been made of it, or no measurements taken to guide its re-erection.' The fact is, that it was most carefully drawn to scale; the complete elevation is available, and will be used as a guide in the rebuilding. Several photographs have also been secured, so that in this respect there is nothing to be desired. We have now considered the whole of the charges made against Mr. Guinness. We believe we have either shown them to be groundless or irrelevant, and we are surprised that such an ebullition of ill-temper and envious feelings should have been obtruded on a scientific journal as a fair criticism on a matter that we admit 'is of imperial and not merely of local interest.'"

ARCHITECTURAL MUSINGS.

The Building Art! the Building Art!
Of the world, its old and grandest part,
It liveth to-day, though not of erst,
When prophet and prince in its ways were versed.
Ere Solomon's temple or Babel's tower,
The "mystic tie" of the mason's power,—
Were known and felt with a will direct,
For a craftsman then was each architect.

The Building Art! the Building Art!
Of the Grecian scroll and the Roman chart;
Oh, never again while the world's moon
Waxes and wanes we'll view such ruin;
Two thousand years have passed away,
And rich though in ruin, they are robed to day,
Shade of each heroic soul elect,
Both craftsman alike and architect.

The Building Art! the Building Art!
Of the palace, and hall, and public mart,
Of tunnel and tower, of keep and fort,
Of castle or church, of crypt or court;
Of which phase in its path of fame,
Wouldst thou, reader, strive to aim—
The column, or arch, or bressumer "ect,"
Of y^{e} modern craftsman architect?

The Building Art! the Building Art!
What lessons those "strong records" impart,
In Athens outstretched, in Egypt hid,
In each hieroglyphic pyramid,
The mighty duct and the wondrous dome,
Above and below eternal Rome,
The Celtic round tower still erect,
Of craftsman, scholar and architect.

The Building Art! the Building Art!
The brow, the brain, and the human heart,
The master-mind, and the skilful hand,
Ready to form whatever is plann'd—
Granite temple or marble throne,
Statue or frieze, each traceried stone;
The image outlasts the intellect
Of craftsman, artist and architect.

The Building Art! the Building Art!
Of student and lover, a word apart—
Like a truant that lagged at a stagnant pool,
I would lash you again to your Grecian school,
And teach you to copy, without the blot
Of *outre* Christian or *ogre* Goth,
And win the laurels that whilom deck'd
The brows of each noble architect. C. C. H——Y.

AN OPEN VIEW OF THE DIPLOMA QUESTION.

WE have a sort of foretaste of the coming discussion on the diploma subject, in the numerous communications and floating correspondence which have so largely abounded of late, revealing great diversity of opinions, and struggle for personal or party distinction. The Institute has issued a circular letter which will be found below, and as an independent focus of opinion is also in existence, we may at once condemn this attempt at antagonism, for it is very improbable that any scheme uncountenanced by the chartered body would command general confidence and support.

The Institute, taking the initiative in this question – to which indeed it was moved from without—proposed the simple and strictly defensible course of making an experiment, by offering a certificate of ability to those of its own members who should voluntarily submit to an examination. Then came a charge of an attempt at self-exaltation, to the prejudice of the profession in general, and the advocacy of a compulsory system; and this again has been equipoised by the views of those who think that, even admitting an examination to be desirable, the theoretical desideratum is wholly unattainable in practice.

To understand this question aright, it would be necessary to revert to professional incidents of a somewhat extended period. It had long been felt by the professors of architecture, that the merits of their art would never be rightly understood or adequately esteemed until some elementary acquaintance with its rules and characteristics came to be regarded as a necessary acquisition and accomplishment, by men of high position and enlarged intelligence.

The erection of London into a seat of education, on principles consistent with the advanced requirements of the age, where the highest secular instruction was to be laid open to disciples of every religious creed, was an event calculated to produce great and beneficial effects, and the example has received recognition and adoption to some extent by the older seats of learning.

The institution of classes for imparting information upon architecture, was an early feature of the London colleges, and hundreds of students who have passed these courses must have become conversant with the historical, the scientific, the artlike, and in short with all the bearings of the subject which admit of being orally or catechetically communicated. But it is not altogether impossible that the greater and more public object has been occasionally narrowed both by students and teachers, and for the higher aspiration of becoming intelligent patrons and discriminating judges, the hopes and aims of professional rivalry and emolument have been substituted. The information given is precisely that which those should possess who have to form opinions or to speak of matters architectural; and it forms an admirable preliminary to regular professional training, but no more; for it is unnecessary that the attendant on these lectures should ever have handled the T-square, have descended into foundation trenches, or have reached the acclivities of a roof, yet the youth fresh from the lecture-room would be better qualified to pass such an examination as college lectures are likely to propose than one practised architect in a score, because such an examination must necessarily confine its scope to those crude and tangible points which admit of systematic acquisition, and are undoubtedly of some collateral value, but which it would be erroneous to consider as the leading criterion of the knowledge that is really desirable.

One man of superior genius—confined though it be to some one department only—benefits his profession and advances the interests of art more than a thousand who are simply versed in the theories of the schools, yet how often would the trap of examination enable systematic mediocrity to laugh at the overthrow of experience and genius. The grand evil, however, seems to be, that some who lack the attainments of the school, and for the patient gathering of experience have no other substitute than bold assumption, are among the professors of a noble vocation. Now, it should be recollected that two sources of information lie open to the inquirer—namely, books and things—and that the students of the latter class, such as Watt, Stephenson, &c., have produced a large amount of public benefit, and it would have been most impolitic to have excluded them from any profession; still the difficulty of discrimination would be very great, and it, therefore, appears to us that some room at present being admitted to exist for the besom of reform, such a course will be most worthy of adoption as shall combine a considerable amount of practical information with some theoretical qualification. The simple ventilation, however, which has been given to the subject will, without doubt, be productive of wholesome results.

(Circular above referred to.)

"We are instructed by the President and Council of the Royal Institute of British Architects, to request that you will be good enough to bring before the notice of your society the enclosed proposal of the council for establishing a system of Architectural Examination, and we should feel much obliged if you would, by the end of September, if possible, favour us with the opinion of your society upon the said proposal, and with any suggestion or modification which may be recommended by its members, collectively or individually.

"We should, of course, be happy to receive such suggestions in any form which may be considered best by your society, but we may be allowed to mention that, as there are several societies whose opinion we hope to elicit, it would serve to put the whole matter in a clearer way for working out, if your suggestions could be embodied in a series of resolutions which should either adopt, alter, or reject those put forward by the council, and, so far as possible, run parallel with them.

"We could then collate together, without much difficulty, the opinions of the several societies, and ascertain how nearly they coincide, or wherein they differ most importantly.

"We annex also a copy of the resolutions passed by the members of the Institute, the adjournment having been agreed to in order to ascertain, if possible, the opinion of those gentlemen whose residence and practice are away from London, and who are, no doubt, fully represented by your society and others.

"We need scarcely mention, that the council attach great importance to the success of this movement, and would wish to know whether (although perhaps differing as to the detail) your society would be in a position to assist in carrying it out effectively."

THE METROPOLITAN (UNDERGROUND) RAILWAY.

Recently having had the opportunity of personally inspecting the progress so far attained in the works for this subterranean line of communication, and having noted some of its features, we had determined to particularize them specially, but being anticipated by our excellent cotemporary, the *Engineer*, we quote the following able description from its pages:—

The important line of communication which is to afford to the Great Western and North-western, the Midland, and other northern lines, a direct entrance into the heart of the city of London, and which is ultimately to bring within the system the calamitous Eastern Counties, and connect it with its respectable brethren, is making most satisfactory progress. Within eighteen months of the present time any person resident in the city wishing to go to any part of the north, north-west, or west of England, will have one station within easy walking distance at which he can book himself for the Land's End or John o' Groat's. Another twelvemonth will, no doubt, witness the construction of a short branch from Victoria-street to Finsbury-circus to meet a short extension from Bishopsgate, and then the whole of the eastern counties of England will be as accessible as those of the west. By this time sufficient progress may have been made with the railway which will cross the Thames at Blackfriars, to enable us to state with certainty when the London, Chatham, and Dover Western Extension will be ready for traffic; and when that is completed there will not be a part of Great Britain accessible by railway to which a passenger may not be booked direct in the new Victoria-street. The line in course of construction to Charing-cross will hardly be allowed to find its *ultima thule* at that spot, and will probably throw out some projections to reach a northern and western line. Within seven years the metropolis will be completely intersected, and each suburban district will have its railway as it has now its line of tedious omnibuses, but a sum of from ten to fifteen millions of money will be required to be expended to accomplish these results.

The Metropolitan (Underground) Railway, with which we have now more especially to deal, will absorb a million and a-half at the least before it is opened for traffic, and the line will then be probably one of the most remunerative in the country. It will commence at the Paddington Station of the Great Western Railway, into which it will run on a low level, and then gradually descend till it begins to burrow under the ground. Passing under, and in a line with, the New-road it will pick up the traffic of the London and North-Western Railway at Euston-square, which will be carried to it by an underground branch; at King's-cross it will pick up the passengers from the Midland Railway and the north of England, and proceed to Farringdon-street. Here it will throw out a branch into, or rather under, Smithfield, and wait until the London and Chatham and Dover shall meet it from the other side of the Thames.

The underground railway will have a double line of rails, each, however, of the mixed guage, so as to accommodate the broad as well as the narrow guage carriages. The roadway will be 28 ft. 6 in. in width, and the height from the rail to the soffit 15 ft. The contracts for the works have been taken by two firms: Mr. Jay has the section from Farringdon-street to Euston-square, and beyond that to Paddington has been taken by Messrs. Smith and Knight.

The most important, and indeed the heaviest, part of the line is at King's-cross. No person who has not had the opportunity of personally inspecting the amount and description of work that is going on at this spot can form any adequate idea of the apparently hopelessly complicated nature of the tunnelling. It is required at this point that the main line should receive two branches coming in opposite directions, and crossing each other at a few yards before entering the main tunnel, and all these communications have to be made either under or in immediate proximity to the rapid and continually-flowing Fleet river or ditch; and, to increase the difficulty, houses for the pointsmen and signalmen have to be built up at the junctions, and all this work has to be carried on at some 30 ft. below the existing road. Straightforward tunnelling, or even going round a corner at a sharp curve, with nothing, to all outward appearance, to guide you as to the spot at which you may come out, is simple and easy to those who understand the business; but such a complication as that at King's-cross seems thoroughly bewildering. A Chinese puzzle, navigation in a fog, a journey through an American forest or Indian jungle, seems plain and simple in comparison with the task which Mr. Jay's moles have to carry out at this spot. Without asking the reader to descend a series of almost perdendicular ladders, every round of which is slippery with soft blue clay, and where a false step may land the incautious explorer in the dark chambers far below, we will endeavour to explain the process by which the puzzle is being worked out.

The first thing to be done was to get an outlet for carrying away the earth, which was required to be excavated. For this purpose the existing railway at King's-cross afforded many facilities. The short branch to run under Maiden-lane was therefore the first attempted, and this short piece—a tunnel of about a quarter of a mile in length—was taken in hand, and is now completed. Temporary rails are laid down in it, and waggons running upon these rails, drawn by horses, convey away the earth on to the railway, where, when a sufficient number are accumulated, they are taken by a locomotive, and their contents deposited near some works now being carried on by the New River Company, about three miles distance from King's-cross. By this arrangement an enormous amount of labour is saved, and the passage of innumerable carts through the streets, carrying away the earth, is avoided.

This short eastern branch, which runs in the direction of Maiden-lane, passes under the Fleet river, now more generally known as the Fleet sewer. It is, however, a stream or river which has its rise in the Hampstead and Highgate Hills, flows through Kentish Town, and enters the Thames close to Blackfriars Bridge, at the same spot at which it emptied itself centuries since, when it formed the boundary of the city of London, and Ludgate stood at the foot of the hill, on its banks. In rainy weather, or at the time of a thaw, after a heavy fall of snow, an immense quantity of water is poured down this steam, and when this great flow takes place at the time of high water in the Thames, and the current of water cannot find a rapid exit, it flows back, and completely fills the covered sewer. On various occasions, while the excavations were going on, the sewer became thus completely charged with the back water, greatly increasing the difficulties connected with the work. It was necessary in the first instance to cut a new channel for this Fleet river, and divert its waters from the spot under which the tunnelling was carried on. The levels of the tunnels were not, however, sufficiently low to admit of the excavations going on beneath the bed of the sewer. The arch of the tunnel is about 2 ft. higher than the bottom of the sewer. A massive iron aqueduct, 8 ft. 6 in. in diameter, is stretched across the tunnel, resting upon the side walls, but the under side of it is 2ft. lower than the arch of the tunnel, and through this the water of the Fleet is carried. Trains passing along this tunnel will have to lower their chimney funnels, or they will run the risk of tapping the sewer in a very inconvenient manner. The railway passes close under the outer wall of the station at King's-cross, and very great precautions were necessary at this spot during the very critical time when the workmen were dealing with this sewer and the tunnelling, owing to the very small depth of earth between the surface and the crown of the tunnel, and the immense pressure of the heavy brickwork of the station, and of the house property at the entrance of Maiden-lane.

At King's-cross there are two branch lines running up to the station, one on the east, the other on the west side. These, as we have already stated, have to be so constructed as to communicate with and run into the main line which passes along the New-road to Farringdon-street. The two lines run in on a curve, the one from the west running in an easterly, the other from the east in a westerly direction, and they therefore cross each other something in the form of a letter X. At the point of intersection the arch of the tunnel has in consequence to be groined. This involves some very nice calculations of details in the fixing of the centreings and supports, and the two lines, after crossing each other, have to be led into the main line. Now, as the main tunnel is 28 feet 9 inches in width, and the branch lines about 14 feet, the necessity presents itself to combine in one arch at the point of junction two arches of a different radius. The span of the arch of a tunnel 14 ft. in width is, of course, very different from that of one of double the width, and the height of each must vary in proportion to the increased radius. The main line, too, is 28 ft. in width, the branches which are to run into it are 14 ft. at the point of juncture; as the lines run in on a curve the width must be 42 ft. at the least, and this gradually diminishes till the ordinary width of the main line is attained. The tunnelling, therefore, has to be what is known as bell-mouthed. On the Crystal Palace and West End line there is a tunnel of this description, but in that case the mouth or entrance is constructed above ground. At King's-cross all this work is under the ground. The tunnel not only increases in width at every inch of its progress, but it has to make a proportionate rise in the height of its arch, owing to the increased span. The arch rises about 6 ft. in 50 ft. of length of the bell month, and there is of course a corresponding elevation required in the arch of the smaller tunnels. As though it were not enough to meet with one difficulty of this sort, it is required to be overcome a second time for the second branch going eastward.

The tunnelling has to be carried out in forms which may be represented by a monogram formed of the letter X and two Y's placed thus: ⊣<>⊢, each leg of the letter X forming the upper limb of the Y's, and all the arching and building up has to be made to fit accurately together. An ant's nest, a rabbit warren, a colony of beavers, or mole's burrow, would not be more intricate. We fancy that we have explored the whole region, and traversed the whole maze, when we come upon the flicker of candles through an interminable tangle of timber, and are informed that the work there is the pointsman's house, with retiring rooms. The immense baulks of timber supports become more and more numerous, and we feel something of nervousness when we are told that this was and is the most critical part of the business. The walls and arches of the small and large tunnels of the great bell mouth press with such immense force on this pointsman's dwelling, which is at the centre of the complicated junction, that it has been necessary to use the greatest possible precautions to prevent the whole from coming to one grand collapse. There are timbers upright, horizontal, diagonal, straight, curved, interlacing, and crossing and recrossing each other, till it becomes a marvel how it was possible to have got such masses under the earth and into any useful position. The ground plan has now grown more complicated, the monogram of the two Y's and the X has received the addition of one large and two small O's, and these letters are placed in the forks of the two horizontally placed Y's. The "round house," which is a sort of key of the position, is completely covered in by a circular dome, and here will be stationed the switchmen and signalmen, who will attend to the points necessary for running the branch traffic on to the main line; for the through trains—that is, from Paddington to the city—there will be no points to attend to at the junction, as the switches will, of course, be open.

The brickwork of the tunnel is three-course, or 2 ft. 8 in. in thickness, and some idea of the extent of the work may be judged from the fact that 10,000 bricks are swallowed up for each yard formed as the tunnel advances. The shafts, as above stated, are placed about 90 ft. apart, and the work can be carried on with much greater rapidity by having the shafts more numerous, as each shaft affords two faces against which the excavators can work at the same time. The progress of tunnelling depends upon the number of men who can be employed simultaneously; and by the plan adopted by Mr. Jay, the tunnel is carried on in sections of 45 ft. each way. The rate of progress is about 20 yards per week, the eastern section is about 1,600 yards, so that eighty weeks from the commencement would suffice to complete this portion of the line. The upper side of the arch of the tunnel will vary from 10 ft. to 12 feet in depth below the level of the Euston-road, as far as Tottenham-court-road; beyond this part the depth will decrease until in some parts there will not be more then 3 ft. between the roadway and the top of the tunnel. The Fleet sewer has to be passed twice before the railway reaches the City terminus, and will have to be diverted and treated in the same manner as at King's-cross. The sewer, which formerly ran along the centre of the New-road, has been diverted to the south side, and now passes under the foot pavement. The tunnelling is built in the blue clay. In one part of the line the excavations will pass through sand, and it is feared no small quantity of water, and in another part a small strata of gravel. As at present arranged, there will be communications formed with the railways and passenger stations at Baker-street, Tottenham-court-road, Euston-square, King's-cross, Victoria-street, and Smithfield. Up to the present time the excavations have been carried on without any serious casualty. The difficult constructive details have been arranged and carried out under the direction of Mr. Houselander, the superintendent of the works, in a manner which reflects the highest credit upon that gentleman, and prove the vast resources of the eminent firm of Messrs. Jay and Co., the contractors.

THE ARCHITECTURE OF THE FUTURE.

[Translated from the Feuilleton of *L'Opinion Nationale.*]

LA BRUYERE complained, two hundred years ago, that *all* had been said, and that writers were condemned merely to repeat their predecessors; nevertheless, in the following century, Voltaire and Rousseau, Diderot and Montesquieu, discovered a number of ideas, sufficiently new, and enunciated them in a style sufficiently original to bring about a sensible modification in the ideas, political and philosophical, of their readers, and one fine day the French Revolution burst forth.

In the same way, for a good century past, architects have pretended that *all* had been achieved in architecture, and that all that remained to be done was, out of the immense number of examples, to select the three or four of the finest monuments built by the Greeks or Romans. We know the celebrated scene in "The Bear and the Pasha," where the great Schahababam asks for a learned fish, and Lagingeole answers so much to the point:—"A fish? I have what you want; take my bear." The same scene has been enacted for the last fifty years throughout Europe whenever a great building has to be erected.

"I want an Exchange," says the city of Paris. "An Exchange?" replies the architect; "I have just what you want; depend on me." Whereupon he draws out of his portfolio a Grecian temple, which he proceeds to construct in all haste. "We would wish a church," says the commission of public worship. "A church? Indeed! I have just the plan for you, and for a few thousands you can have your wish." And the artist takes up his Grecian temple and has it built a second time.

Other architects, less exclusive, propose, as models for museums or mayoralties, the Pantheon, St. Peter's at Rome, or the Cathedral of Strasbourg. But all agree in declaring, that outside the Greek, the Roman, or the Gothic, there is no safety, and that no great building could be erected on a new plan.

Meanwhile, in the seventeenth century, a doctor, who had no cook, had observed the lid of his pot, as it were involuntarily, rise from time to time, which led him to believe that steam possessed a certain power. The force thus discovered by him was utilized by others, and one hundred and fifty years after the doctor had boiled his own pot, enormous steam factories and innumerable railways spread over the surface of the globe; the cooking pot of the good doctor had produced in the material world as profound a revolution as the writings of Rousseau, Diderot, and Montesquieu had in the moral.

Behold our architects in a fix! They had been able, with the greatest nicety, to lodge in their Greek temple the vespers and the three per cents.; but with all their ingenuity they could not, in new editions of the Parthenon, accommodate the travellers, baggage, and merchandize which flow into the railway stations, or shelter the hundreds of locomotives and thousands of carriages under the new adaptations of the Roman Basilica. Besides, without being miserly, public companies look closer after expenditure than the minister of public works. They desire fine buildings, but they will not sacrifice to the fantasies of architects either the requirements of the service or the money of the shareholders.

Archimedes having omitted to discover steam power, the Greeks had no railway stations to construct; having left no model for imitation, something new must be found out. Something new was discovered. Some of our stations are truly beautiful, and have good character, although not copied from any model of Rome or Athens. Therein is progress; a happy innovation! I have no doubt much more will be done; but it is of much importance to hit upon a new path. Meanwhile, according as railways were developed and extended, as they carried more passengers and merchandize, not only were the ancient forms of building found unsuitable, but the materials hitherto employed were found insufficient. In order to shelter long trains on three or four lines of rail, wooden scantlings for roofs of fearful weight were employed, and involved enormous cost, with risk of destruction in a few minutes by fire.

The idea of trying wrought-iron girders was started. The advantages became at once apparent; these new roofs cost less money, are infinitely less in weight, and are fireproof; and finally, inasmuch as the enormous wooden beams were ugly, the iron girders are graceful. Compare, as you go to Bordeaux, the horrible station at Orleans and the charming one at Tours; you will no longer have doubt upon the subject. An immense stride was made; architects became possessed of new materials, which the Egyptians, Greeks, and Romans had not. Iron and glass were substituted in many cases with great advantage for stone, wood, and slate. Emancipated from routine, we had only to go resolutely forward.

In certain buildings, as in the library of St. Genevieve, and the Palace of Industry, the ancient and modern materials were wedded; in others, the Crystal Palace of London, Sydenham Palace, and the markets of Paris, these latter were exclusively employed. The reading-room of the library of St. Genevieve, situated on the first floor, and roofed in iron, where the girders assist in the general decoration, is alike original and beautiful. If the exterior of the Palace of Industry offers subject for criticism, it is impossible not to be deeply impressed with the interior, when we stand in the middle of the nave, so elegant and daring in its immense proportions. As to the market *(les halles)*, there is little room for criticism or fault-finding; it is up to the present the *chef-d'œuvre* of the new architecture.

Above all, in the construction of bridges the new materials are precious. We know until the last few years how much time and money were expended in the piles of a bridge. Now, iron bearers being, with equal resistance, much lighter than those of timber, a metal bridge necessitates much fewer piles than one of wood, much less one of stone; besides, it is more rapidly constructed, costs much less, and interferes less with the navigation. The stone bridge of Bordeaux cost twelve years' labour, at an expense of nearly £1,000,000 sterling. The iron tubular bridge, recently constructed some few yards distant, uniting the Orleans Railway with that of the south of France, has been constructed in two years, and has only cost £140,000. The stone bridge has twenty arches, the other only six. The workmen who fixed the piles have given evidence of moral courage. The ingenious but somewhat startling system at present employed for this sort of work is this:—A metal tube, whose diameter is that of the intended pile, is submerged. When it has reached the bottom of the river, air is forced in by a steam-engine until the water is driven out. The workmen then descend into this submarine workshop, and work at their ease by the dubious light of a few lamps, in air of the pressure of two atmospheres. If unfortunately an accident occurred to the engine, if the pump ceased to supply air, or the air in the tube suddenly burst out, the unfortunate workmen would be instantly suffocated or drowned. The several parts of these bridges are manufactured often very far from the place where they are to be put together. The Republic of Nicaragua has recently ordered a bridge from a contractor in London, just as a New York *elegante* would order a dress from a Paris dressmaker.

We see what resources the progress of science offers to our engineers and to our architects. Immense structures to raise, to which it is, happily, impossible to apply the forms invented by the ancients for their palaces and temples; for these buildings of novel form, new materials, stronger, lighter, and cheaper, than those heretofore in use: do we not then behold a happy opportunity for continuing in architecture the revolution already achieved in politics and industry! Oh! if it pleased Heaven to give us now an architect of genius, such as those who invented the types of Grecian temples, Roman basilicas, and Gothic churches! how would he not avail himself of this moment so favourable for the renewal of his art and the creation of new types, superior, doubtless, in beauty and grandeur to all that Ancient Greece or Ancient Rome, Germany of the Middle Age and Italy in Renaissance, have achieved of great or beautiful!—Signed, EDMOND VILLETARD.

TUBULAR GIRDERS IN BUILDINGS.

THE employment of the iron girders upon the tubular principle in the erection of commercial structures, where the greatest space and light are required, has just received a practical proof of its efficiency by the completion of the magnificent stack of business premises intended for the joint occupation of the Messrs. Courtauld and the Messrs. Wetford in Aldermanbury. The principal iron girder sustains the whole weight of the private portion of the premises of the former, and is capable, according to the *data* of Fairbairn, Tredgold, and others, of bearing tenfold its present burden. By its means the whole of the business part of the establishment is rendered exceedingly spacious and free from impeding archways or pillars, while it admits of the entrance from above of an expansive flood of the pure northern light, so requisite for the examination of silks, crapes, &c. Light is transmitted to the basement storey from the same source, without the employment of an open well-hole, and thus none of the ground-floor space is sacrificed. These are bold innovations, readily appreciated by business men, who will at once find, that while the architect (Mr. Woodthorp) has broken through the general monotony of similar erections, he has, by getting rid of all unnecessary ornament, stringently kept in view the essential elements of utility, economy, and effect.—*Mechanics' Magazine.*

ART UNION OF IRELAND.

ESTABLISHED 1858.

The recently published report of the Committee for year 1859-60 has reached us, and certainly presents a cheering aspect for an association as yet comparatively in its infancy. As stated in previous numbers of this journal, the formation of an Art Union was at best a hazardous speculation, replete with difficulty and up-hill labour only to be conquered by resolution and energy of purpose, soundness of principle, and that indispensable accompaniment to all new projects—"*patronage.*" However, judging from results, these elements would seem to have entered, *ab initio*, into the constitution of the Art Union of Ireland, and health and fair promise of longevity is the consequence. We will not now refer particularly to the details of its principles, we have done so before, and practice has developed their wisdom and honesty; in the abstract, however, "art" has been materially benefitted, the public taste has been improved and gratified, and the promoters may regard with some pride the successful rearing of that structure for which their plans and estimates were evidently carefully framed. Our desire—if that be of any service, however insignificant—is to see the Institution succeed, and if it does so in the same ratio—as evidenced by figures and facts—as it has done up to the present, we may reasonably augur a prosperous future. A word, however, as to "effects." There is no effect without a "cause," and if previous institutions of similar character failed, there must be some reason why *this* should be the reverse; that reason may, we believe, be easily individualized—if not solely, certainly mainly—in the person of the Secretary, Mr. George F. Mulvany, a gentleman to whose exertions and ability the result is attributable, and to whom, for his devotion to the progress of art *generally*, the public owe a national debt of gratitude.

A WORD ABOUT VICTORIA-STREET, LONDON.

What a sensation of blank and utter disappointment does the condition of Victoria-street cause to the visitor in London, who expects with reasonable curiosity to find a grand palatial thoroughfare suitable in appearance to its august denomination! The streets named after Queens Anne, Charlotte, and Adelaide, are exponents of the manner of their respective days; but we are accustomed, and rightly, to view our reigning mistress as a building Queen, like Semiramis of Babylon, Dido of Carthage, or the Carian Artemisia; and the works of either of these several personages, or even if taken collectively, would hardly admit of comparison with the works of Victoria. Instead of compassing her territory with a thong, it is necessary to make a great circle of the earth to visit her tributary states, while spring and sunshine are never wholly absent from her vast dominions. Railways, bridges, churches, palaces, exchanges, museums, houses of parliament, offices for the administration of public business, and hotels scarcely less extensive and commanding, excite astonishment in the old world and the new. Her divines, artists, men of science, and merchants are scattered wherever the business of civilization is to be promoted or begun, her richly-laden galleons of peace are known in every port, and her ships of war on every sea. Nor is she more respected on the ground of her power than for high and exemplary personal qualities; yet, in the very district of the Court, close to the seat of Parliament, under the shadow of Westminster Abbey, and almost adjacent to the Queen's own residence, is this great stigma allowed to exist; and the abandonment of the work is only the more strongly contrasted by the pretentious nature of the beginning, as the ruinous carcases are colossal beyond those of any other street; for London, although it may compete with any city in point of general effect, cannot boast of much that is gigantic. But surely it is only necessary that public attention should be drawn to the deplorable condition of this street, and to its very unsatisfactory influence on the minds of strangers, to induce some new effort for securing its completion in the style originally contemplated, or to manifest the propriety of a change of dedication! There is Old Bond-street and New Bond-street, and we should presume to suggest that this might be appropriately designated "Westminster Bond-street."

The Commissioners of Public Works have accepted the proposal of Mr. Joseph Bryan, of Dunmanway, for building extensive additions to the District Model Schools, Dunmanway, Co. Cork.

BUILDING GROUND AT TERENURE.

A few years ago one of the most favourite holiday resorts in the vicinity of Dublin was the demesne known as "Bourne's, at Terenure," and by the kind sanction of its hospitable proprietor the banks of its glassy lake were the scene of many a convivial gathering. Subsequently, however, the property changed hands, and the present proprietor, doubtless sensible of the rapidly increasing demand in that locality for building sites, has decided on portioning it off into lots, with frontages of about 1,500 feet to the lake, and a like amount to a spacious carriage-drive. However much we may regret, for the sake of "auld lang syne," the proposed innovation, yet we are bound to acknowledge that, combined with facilities presented for building operations—materials being close at hand—the beauty of the site and the surrounding scenery at once proclaims the field to be a desirable one for investment, and well worthy the consideration of such of our readers as purpose embarking in "*the bricks and mortar.*"

INDURATION OF THE EXTERIOR OF NEW MUSEUM, TRINITY COLLEGE, DUBLIN.

Messrs. P. S. Barff and Co. have now completed the induration of the Portland stone work of the Museum, Trinity College. Owing to the wet season their progress has been slow, but in order to ensure the success of the operation every attention has been paid to the application of Ransome's patent solutions. As regards the appearance of the work there cannot be two opinions; the surface of the stone is as natural as if no material had been applied to it. It is perfectly clean, and every trace of discolouration has been removed. The stone has been rendered hard and non-absorbent—a deposit of insoluble silicate of lime having been placed in all its pores. The material used is *not* a *pigment*. It is formed by the chemical decomposition of silicate of soda by the chloride of calcium; and the result—silicate of lime—attaches itself to the lime of which the stone is composed, forming with it a homogeneous mass,—excluding damp, and therefore preventing the disintegrating effects of frost and water as well as the various noxious properties of the atmosphere. In the preservation of stone, it leaves untouched the character of the material to which it is applied. Other systems have been tried at the houses of Parliament and elsewhere, but these have this great defect—that they perfectly conceal the material of which the building is constructed, and have the appearance of badly executed distemper colouring The question of their durability is very doubtful as in the Speaker's court of the House of Commons the work which has not long been executed is being re-coated in many parts. On the whole Mr. Ransome's process is by far the best in use at present. The induration was committed by the College authorities to Messrs Ransome and Co., of Ipswich. Messrs. Barff and Co., of Potter's-alley, Dublin, were the contractors.

VANDALISM *VERSUS* PROGRESS.

A somewhat acrimonious interchange of opinion has taken place concerning the proposed removal of the Hereford Town-hall, and the cry of vandalism has been raised as in the recent and more reasonable case of the Gusten Hall at Worcester. In that instance a building of great antiquity, with architectural features of considerable interest, was on the eve of demolition from sheer indifference to its claims—a wish to be spared the charge of needful reparation, or to serve some most secondary purpose of immediate convenience.

When we recollect how much damage the antiquities of this island have suffered from causes of a parallel kind, it is perfectly natural that we should welcome any wholesome efforts at conservatism; but when motives of personal interest and feeling are demonstrated, the advocates forfeit their claim to general confidence, and deprive the subject of its most dignified ground of attention.

The circumstances connected with the two venerable cities of Worcester and Hereford are perfectly distinct, and indeed almost opposite in character. In the first the destruction of the Gusten Hall was to be censured as uncalled for by any pressing necessity, but if we were to make the conservation of every old and dilapidated building, no matter how confirmed its disuetude, obsolete its purpose, or obstructive its existence, paramount to all other considerations, progress and improvement would be at an end.

Now it appears that in nearly the widest part of the central *place* of Hereford which, by the confluence of two streets takes a sort of ≻ form, stands the timber edifice known as the Guildhall, and we may say a very interesting example of its class, but certain changes have for some years been in progress under the guidance of an Improvement Committee, whose claim to the merit of a just and rational course we see no reason to impugn, and deem the removal of a building under such a sanction to be as much in accordance with the ordinances of nature and the conditions of our being as the death of a patriarch, or any other consummation of an appointed career.

THE EXHIBITION OF 1862.

THE International Exhibition proposed to take place in London in 1862, having received such an amount of preliminary support—royal and popular—as must place it beyond the influence of pecuniary peril, and a site having been appropriated at South Kensington, we may not unreasonably look for an early intimation concerning the nature of the structure to be raised there. We recollect how little of direct benefit arose from the general competition for the building of 1851, open as it was to men of all schools and countries, and how imminent was the probability of a merely commonplace result; but we also recollect that by the attention drawn to the subject, the knowledge that suggestions were courted, and that no letters patent existed in favour of any individual or class, a design was ultimately, though tardily, obtained, whose novelty aptitude and merit have been universally admitted, and whose characteristics have been widely copied. The trammels of art were loosened, and the scope of invention expanded by the vigorous innovation; and while the students of architecture were devoting themselves to the discovery of a sixth order, the grand desideratum was suddenly developed from an extraneous source, opening a new sphere of design, and, comparatively speaking, a new gift of nature in the vastly-extended application of iron to structural uses.

Reverting for a moment to the early steps of that undertaking, we find that the invitation for designs was accepted by thirty-eight foreign, one hundred and twenty-eight London, and fifty-one provincial competitors; but it appears that although some of the works were deemed very meritorious, there was not one strictly suited to the object in view, and the whole were consequently rejected. Next, it seems, that those to whom the task of selection had been entrusted set about concocting a plan of their own, a course perhaps more creditable to their zeal than discretion, and productive only of an example of crudeness and deformity, from which its originators and the public had a fortunate escape by the appearance of Mr. Paxton, now Sir Joseph, with a sensible scheme, backed by the support of the late Duke of Devonshire. A conjunction of ability and patronage are of but too rare occurrence, even though the leading feature only should be assigned to the originator, and the qualities of gracefulness and that nice constructive economy to which the eye is accustomed in the re-edified work at Sydenham attributed to other minds, just as while the Dublin Bazaar of 1827 may claim the initiation of such expositions within the United Kingdom, a demarcation must be admitted between the germ and its subsequent fruition. Nor should the part so usefully taken by the Society of Arts be passed forgetfully over, as that body rendered good service to the first, and is now engaged on the preliminary labours of the second exhibition.

Great allowance must be made and indulgence given with regard to the doings of ten years since, but the intervening period, from the present time to 1862, is not too great for the deliberate and mature organization of so comprehensive a matter, although many departments may go simultaneously forward; and we would by no means recommend the assumption, that because an immense stride was taken at the onset, no important advance is likely to be now made; for, on the contrary, we hold that, while similar materials may form the staple of the new work, a wide field is open with respect to their applications as well as to the general features of design. Instead, therefore, of a single month as before, let there be three months at least for producing plans, and instead of that remorseless haste which so overtasked the powers of those employed, we would point to the better method and superior economy of letting all things be done seemly and in order.

TOPICS OF ARCHITECTURAL POLICY.

As railway boards issue to their proprietors notices of Bills in Parliament bearing upon their undertakings and prospects, so has the Royal Institute of British Architects issued to its members a communication embracing many points of professional interest, upon which it has lately exercised, or now proposes to exercise its agency. From this statement it appears that the Institute has addressed some remarks to the Mayor of Hereford respecting the old Town-hall of that city, alluded to in another column. On the examination question, it has addressed the various provincial architectural societies in a circular letter which will be found elsewhere *in extenso*. It has also shewn great activity and interest with respect to the safety of certain churches, towers, and steeples in the city of London, endangered by the probable operation of the Act for the Union of Benefices. Next it furnishes some particulars relative to thecompetition for the Palais de Justice at Brussels, received through the Committee of Privy Council for Trade, and finally it supplies copies of notices received through Her Majesty's Government of a competition for the intended new opera house at Vienna.

The attention and assistance of architects is also drawn to and requested with respect to the antiquities and works of interest, the safety of which may be in any manner affected.

OBSERVATIONS ON STREET RAILWAYS.

SOMEWHAT sceptical of the desirability of—nay more, positively prejudiced against—the proposed system of horse railways for the streets and thoroughfares of cities and towns, we proceeded, by kind invitation, to Birkenhead, to witness the opening of the first application of the invention in this kingdom; and we may state—at once coming to the point—that, as "seeing is believing," we returned thoroughly convinced of its superiority over the existing method of propelling vehicles, subject to the friction of the roadway, the consequently increasing wear and tear, and labour to the horses.

By the *simple* contrivance—and, after all, all great ends are worked out by comparatively simple means when developed and understood--of a grooved line of rails, varying in guage from 4 ft. 8½ in. to 5ft. 6 in., countersunk in longitudinal sleepers, level with the pavement of the streets, some 70 passengers may be conveyed on a car—of course of much larger dimensions—commodious, tasteful, well ventilated, and perfectly manageable, with infinitely less labour to two horses than one-third the number can by the antiquated "bus" fashion.

Lacking even practical proof—but it has been fully and incontrovertibly demonstrated—the volunteered testimony of such men as Mr. Laird, so well known as one of the greatest naval architects in the kingdom, and moreover a gentleman of peculiar acumen and scientific attainment, and of Mr. Dargan, who pronounced his unqualified admiration of the principle, speaks volumes.

Tramways are now one of the most engrossing topics of the day. Shall we have them here? is an oft-repeated question, and one which we can answer. Mr. Train, who, by-the-way, in energy and resolution of purpose, seems far a-head of his most "go-a-head" fraternity, has expressed his determination to give us Dubliners the benefit of his patent, and from what we learn, the intention will speedily be followed by the development. Again we are asked, Where shall they be laid? is it on Rathmines route first, or Clontarf, or where? Will the corporation sanction them—are the streets too narrow *(par example* Grafton-street)—are they not attended with danger? &c., &c. But these or similar questions have been asked everywhere the project was mooted, and are answered so ably in a general way in a pamphlet under the above title, addressed by the patentee to the Right Hon. Milner Gibson, M.P., President of the Board of Trade, that it best answers our purpose to submit the following quotations therefrom, which will be found to comprehend all elucidation of the principle, and explain away that prejudice which still exists with the minority, but which is the invariable concomitant of every innovation upon old-fashioned customs:—

"When I made up my mind last year to succeed in demonstrating the practicability of these railways in English cities, London was the starting point; but a practical member of parliament having assured me that most of the great undertakings of the day were initiated in the provinces, instancing 'steamboats, railways, gas, water-works, telegraphs—even Rowland Hill was a provincial institution,' I applied to Birkenhead for permission to show them a pattern card of an invention that can be extended as long as customers may require. 'Show its success elsewhere, and then come to London.' This I intend to do. The field is wide; the labourers few. By-and-by the rolling of iron, the cutting of timber, the building of carriages, the erection of stables, the equipping of horses, the making of roads, and the consequent employment of engineers, clerks, contractors, mechanics, conductors, navvies, &c., will be practical proof that in introducing street railways into the old world I have given a boon to the people, and a new source of wealth to the kingdom. During the past fifteen years four hundred millions have been invested in the railways of the country. *Five per cent.* invested in the railways of the city during the next five is *twenty millions sterling!*

"Omnibuses were only introduced into Liverpool thirty years ago, and steamboats, railways, electric wires, gasometers, iron bridges, free trade, reform bills, and volunteers (the *national guard* of the land), have all been born during the Queen's lifetime. So, with faith, hope, and energy, and considerable money, I shall establish, what a Cunard captain aptly calls, the rich man's comfort and the poor man's luxury. When Liverpool has a good hotel, a decent theatre, a respectable ferry boat, and street railways, the 'Borough' should be promoted to a 'City.'

"If I am properly supported by the corporations, the ladies of Lancashire and Cheshire, at no distant day (instead of being packed in a sardine box with a sweep, as in the present omnibus system, or stowed away in the steerage of the Mersey ferry boats—there is no cabin!) can step under cover at any part of Birkenhead into a commodious railway carriage—ride to the pier—walk under a glass arcade into the saloon of the new ferry boat—walk again under a glass arcade from the floating stage to the railway carriage on the Liverpool side, and be taken to St. George's Hall, or the Philharmonic, and thus effect an important saving in *umbrellas!*

"Street railways in England will soon become a great fact—Birkenhead opens the ball. Liverpool follows. Then Manchester, Birmingham, Glasgow, and *Dublin enters the ring;* and London cannot well hold back after building the Metropolitan *Subterranean* Railway. A street railway can be constucted directly over it in as many months as that will require years. The former costs three thousand per mile, the latter three hundred thousand! In the one you travel in the dark, in the other in broad daylight. The street railway accommodates both sexes, while the Metropolitan shuts out one half the population—the ladies! Who crosses in the Thames tunnel? The former stops before every man's door, the latter has stations only at intervals. One starts every five minutes, the other every half minute if required. The Metropolitan blocks up the thoroughfare for months, the street railway for hours only. Surely then if London opens wide her gate to permit the Metropolitan to undermine the city, tunnel through sewers, water-pipes, gas-pipes, and cess-pools, at great cost and great inconvenience, she certainly will not shut it in my face when I respectfully ask permission for a fair trial of my street railway?

"Are not our streets too narrow? asked the leading Christian banker. By no means. London streets are wider than those in American cities. Ludgate-hill and Cheapside are of course in your mind. But when we remember that there are some five hundred miles of streets in and about London adapted to this system, why select the narrowest to commence with? All see an ink spot on the white table-cloth; but who thinks of examining the fabric? That one black sheep prevents the eye from observing the thousand white ones?

"In conclusion, let me say that the egg will shortly be chipped in this country under my patent, at great cost and labour, and I shall endeavour to prevent my chicken (as is too frequently the case with valuable inventions) from becoming somebody else's hen!

"The street railway is an important link in the chain of progress. What is more interesting than to run along the path of improvement from the child Asia to the man Europe, stopping a moment to reflect at the slow-coach-omnibus-system at the half-way station of those middle ages when credulity made up for intelligence—when men did the work of horses and palanquin and sedan chair made way for cab and bus—when captains went to sea without a compass—sailed without chronometers—when geographical knowledge comprised a little patch of sterile land—when philosophy was without scale—astronomy without demonstration—when learning had no printing-press, writing no paper (the tax on which you have laboured so industriously to remove), and paper no ink.

"Those were the days of wax and birch bark parchment—stereotyping on wood and not leaden types—when they made war without powder, shot, mortars, or cannon—without Minie, Colt, or Armstrong—when magnetism had no telegraph, iron no rails, steam no boilers. When flint and steel, instead of lucifer match, made the fire, and the sun-dial instead of the watch told the hour—when trade was without books—correspondence without postage—when merchants kept no ledgers, and shopkeepers no cash books. Surgery had no anatomy then—emetics no ipecacuanha, agues no quinine, clothing no factories, and the diligence had not even succeeded the saddle horse.

"All those days are with the past. The photograph has displaced the daguerreotype. The stereoscope is pushing away the photograph. The telegram saps the brains of the mail bag. and the sewing machine gives antiqnity to the 'Song of the Shirt.'

"Battering rams, and bows and arrows were not used at Solferino. The gas-light supersedes the cocoa-nut lamp. The quill followed the thorn bush, the steel pen the quill, and who so far behind the age as not to use the copying press? Arkwright's cotton jenny coined pounds in England, while Ely Whitney's cotton gin coined dollars in America. So will the introduction of passenger railways confer a blessing upon the public, and add wealth to the nations.

"Let me try, said Fulton, and the steamer went four miles an hour; now the rivers and lakes are filled with floating palaces. Let me put the wire between Washington and Baltimore, petitioned Morse, and all the world wondered! Now the girdle is about to be put about the earth, as Shakespeare said, in forty minutes. Nothing was ever accomplished without talking. How could the government live without an honourable opposition? Truth is sifted through argument. All new inventions must pass through the fiery furnace of scepticism. Nobody believes a fact till demonstrated.

"England has been fifty years in introducing the America volunteer system, but, it is to be hoped, that as many weeks will not pass before she gives a fair trial to the American passenger railway.

"Although the Americans have seized the idea and are practically demonstrating it, by introducing street railways into all their large cities as if it was a modern invention, I find that there is nothing new after all in the system, except its application for passengers. A century ago tramways were used in England.

"Cæsar's roads from hill to hill, still mark the Roman's track. First, pack-horses transported the products of the land from place to place. Even a hundred years ago, this was the custom in Scotland; in fact, in some places in the Highlands, and in some of the hilly parts of Wales, it is the practice of to-day. Wooden sledges drawn by horses succeeded. Then wheel carriages—afterwards wooden tramways—and last came, what the Egyptians used in the age of the pyramids, and the Chinese dnring the Christian era, canals (the first in England was made in 1756). The Asiatic practice of laying down timber in bad roads most likely introduced the wooden rail. Down to the Elizabethan age, coals from Newcastle were taken in carts or on paniers to the sea."

We observe from the proceedings of the Town Commissioners of Kingstown that there is a project in embryo for connecting that important suburb, Rathmines, with Kingstown. This is doubtless a good idea, and if accomplished in manner proposed must confer immense advantages on both localities. The plan is so simple and so natural, that we feel quite amazed at contemplating why it has not been done long since. It is to run a tramway from the Bray Railway at Foxrock across to Kingstown, a distance of about 2 miles, thus bringing Kingstown as near to Rathmines as to Dublin. The route for the Rathmines and Rathgar folk will then be from Miltown station or Harcourt-street to Foxrock by rail, and then by train to Kingstown. We learn that an American company are the projectors, and the capital required is under £10,000. We are quite willing to borrow an idea from our transatlantic brethren, but in a small local enterprise like this we would rather see it in the hands of some of our own capitalists in the neighbourhood.

At the meeting above alluded to the following resolution was unanimously carried:—

"That having learned that a company is about to run a tramway from Foxrock to Kingstown, we desire to take this, the earliest opportunity, to express our approval of such project, as it will afford the numerous inhabitants of Rathmines, Rathgar, and Dundrum a quicker and more agreeable route than at present exists for visiting Kingstown."

VENTILATION AND HEALTH.

It is a startling fact, tested and proved by every-day experience, how much of our existence, and its attendant comforts, lie in our own hands, so far as opportunities offer to promote it. As it is a truth in the religious world that God will never bless the end to the neglect of means, so is it in the physical world. Neglect attending to the claims of health, and the end will duly respond in corresponding debility and suffering. This is an axiom which every one daily hears more or less—it is a truth in which the majority agree; but the lesson having to be learnt, not out of books, but the deeper volume of experience, is ever necessitating the practical results to its victims. Neglect and suffering will ever be companions, because they have sworn fidelity to each other; and while we know that the world is not contented with the second-hand experience, we likewise know that many "ills to which flesh is heir" would be avoided did they but deign to receive it. It is stated to be one of the prevailing fashions of the day to advertise, but all fashion sinks before necessity, for it then becomes a duty, even though the same may be at the expense of being classed among those who print to please. "Health" is a word all understand—its pure enjoyment more so, and who would so falsely deem any means "a sacrifice" to secure it? one would imagine none, and yet it is only by bringing such continually before the public eye in the means of doing so that the same is reminded of the self-obligation. "Fresh air" has almost become a proverb—if judged by enquiry—for securing it, while ventilation now, as a means to do so, offers so many facilities in its simplicity, economy, and comfort, as to be almost a boon within command; to which, in the combination above stated, we feel bound to award our meed of praise to that so well known as "Moore's Patent," 81, Fleet-street, London, to which we cannot pen any higher testimonial than stating their wide and extensive adoption where health is valued, we do so for reasons heretofore given since it is no longer a theory doubtful, but a reality proved, and enjoins upon every one an obligation and a responsibility only estimated by neglected privileges.

Correspondence.

[Note.—*The statements of Correspondents must not be confounded with* "editorial" *remarks.*]

ST. PATRICK'S CATHEDRAL.

TO THE EDITOR OF THE DUBLIN BUILDER.

Sir,—The feeling of mistrust and alarm with which I and many others have regarded the progress of the works at St. Patrick's has been considerably increased by the statements of a correspondent of *The Builder* (London), and permit me to add, *not* decreased by the article quoted from a local contemporary which appeared in *your* last number. A visit to the building, and the scanty information to be obtained by a distant inspection from the outside of the barriers (which I am informed is all that is permitted) is certainly not calculated to reassure. The article which you quote says—"It should be equally well known that the church will be still more indebted to Mr. Guinness for the good *judgment* and *correct taste* with which he directs the expenditure of £20,000 on the works of reparation. His principle is to replace whatever is decayed, adhering *exactly* to the ancient patterns, and making no other alteration than the substitution of a better material. The plan is to restore but not to innovate," &c. Now with the utmost respect for Mr. Guinness' good taste and talents, I would most respectfully remind "your contemporary" that they are those of an *amateur*, and I would with confidence leave it to any member of our profession, or any archæological association in the sister country to say whether any amateur, however accomplished as such, and however assisted by the most intelligent builder in Dublin, would be competent to enter on such an Augean task as the reparation of St. Patrick's—due regard being paid to the vested rights and interests and intentions of the earnest men who many a year ago raised a stately pile for the worship of God, in wonderful perfection and marvellous beauty. In a word, does the "replacing of whatever is decayed" mean that we are to be treated to a reproduction of all the abominations which in the course of a more barbarous age have become encrusted on the ancient fabric—the restorations (?) which have been accomplished by the Gothicists, in whose day Walpole's villa at Strawberry-hill was considered a divine work of Gothic art, and the lath and plaster of Fonthill Abbey not inferior to York Minster itself? Are we to have, for instance (I only state one out of many) a renewal of those buttresses on the south side, with the fearful and wonderful pinnacles surmounted with round balls, which may with a remarkable stretch of courtesy be ascribed as of an Elizabethan character? Are we to have a reinsertion of the bad tracery in the old early English windows in the south side of the nave clerestory? Is in fact nothing to be spared but the very objectionable pseudo-Gothic front of the western façade? Was it absolutely necessary (I am now seeking for information with the utmost deference, as I have no *absolute* reason to doubt the necessity) to remove the whole of the southern wall of the nave? Could no portion of the triforium have been spared demolition, remarkable as it was for great beauty, sacred for the labour and love lavished on it by hands and hearts long mouldered into dust, and hallowed by its enduring existence through six long centuries. With every ancient stone disturbed vanishes some of the charm of the place. Will anyone again be stirred to enthusiasm when he is told that the new walls are but a *tolerably* faithful *copy* of more ancient ones, that had seen kings come to worship within them—had echoed to the tramp of mailed knights, and the requiems of saints carried by devout men to their burial? I repeat that I do not make these remarks with any intention of denying the necessity of the wholesale demolition in question, but with a view to asserting the importance of the operation which renders it highly improper that it should be carried on in a corner, and further with some faint hope of elucidating information. I would now suggest that it is high time that some steps should be taken by the architects of Ireland as a body. Were we not as a body, open to the reproach cast on all our countrymen by our neighbours, of want of unity, we would have among us a properly constituted architectural association that would have long since moved in the matter. In the unhappy absence, however, of such a body, the importance of the question at issue ought to form a common bond of union among us, and I would respectfully suggest to those interested in the matter to join in a respectful and friendly memorial to the Dean and Chapter and Mr. Guinness, which would no doubt be received with courtesy and consideration. Should we sit by unmoved and uninterested, we may be prepared for just and reiterated charges of barbarism from our brethren and friends on the other side of the Channel, who guard so zealously any ancient fabric committed to their care, having furnished another melancholy instance of how far from our city "the sun yokes his studs."—Yours faithfully, **Delta.**

[With reference to the works in question, we are *requested* by the builder, Mr. Timothy Murphy, to state, that recently four architects —viz , Messrs. F. Darley, P. Byrne, Wm. Murray, and James H. Owen—inspected the building, and expressed themselves perfectly satisfied with the character of the restoration; also that, far from the operations being carried on with closed doors, admission is obtainable any time in the day from 6 a.m. to 6 p m., and visits from professionals and the public are courted. We reserve for the present any *editorial* comment.]

THE RECENT WATER SUPPLY COMMISSION.

Sir,—I cannot refrain from offering a few words of congratulation to yourself as an influential advocate, and to those generally interested in the improved supply of water to the metropolis of Ireland.

The space devoted in your last number to the proceedings of the Commission of Inquiry, sufficiently attests your sense of its importance, and there are indeed few subjects of which it would be more difficult to over-rate the effects in regard to social advancement and well being.

The polluted condition of the Liffey and of the Thames have drawn forth a copious flood of animadversion, which happily seems likely to remove the ground of complaint in both cases; the forerunner of cleanliness, both private and public, being an ample supply of pure water.

My memory embraces a time when it was contrary to statute here (in London) to pass the contents of a water-closet into the sewer, but every house had its cesspool, from which the accumulated contents were removed at long intervals, and with nauseous odours, making the night hideous and the surrounding atmosphere the impure vehicle of disease. But we have changed all that: the law prohibits cesspools, and water is supplied, not always indeed in a satisfactory quantity or on terms of perfect equity, but still supplied in a degree of purity only recently attained. The old and injurious surcharge for high service has been removed, therefore closets in the upper storeys are as attainable and economical in that respect as at the bottom of a house. This is indeed a most salutary change, and I have gladly availed myself of the facility to furnish in houses for the industrial classes such conveniences on the upper as well as on the lower floors, and to lay the water on to every storey, which, together with the provision of a shoot for dust, has led to a saving of time and labour as well as to means of increased propriety that have been cordially and thankfully appreciated. The abundant presence of clear, wholesome water would do far more to induce its adoption instead of less wholesome and infinitely more expensive drinks, than the most persuasive eloquence, to say nothing of that purity of house and person it induces—so near akin to purity of mind as to bear out the old saying, that "cleanliness is next to godliness."

A charge by measure is much to be desired, so that the careful may not be liable for the waste occasioned by the negligent, and a constant supply would be in many respects preferable to the existing system of tanks, but as such an arrangement may be difficult to accomplish, cisterns of stone, slate, galvanized iron, or brickwork lined with some variety of Roman cement, or of earthenware, may be advantageously used in lieu of lead. But let the nature of these receptacles be what it may, a good and plentiful supply should be enforced as needful in the same way as lighting, paving, and other observances which tend to the good of the community in general. "The larger a city becomes," says Mr. Sidney Smirke, "and the greater the aggregation of its inhabitants, the more urgent becomes the duty of the legislature to provide by stringent measures and by a vigilant control for the health and well being of the people."

London. **Thomas Morris.**

ST. ANNE'S CHURCH, DUBLIN—QUESTIONABLE TASTE.

TO THE EDITOR OF THE DUBLIN BUILDER.

Sir—An article appears in the September number of the Dublin Builder, announcing the re-opening of St. Anne's Church, briefly noticing the new works—"Two memorial windows constructed with Bath stone dressings, and filled with stained glass . . . . . serving as memorials to Knox the reformer, and Mrs. Hemans respectively—a beautiful and elaborately *carved* pulpit—reading-desk —sedilia and font being likewise added."

Nothing can be more inconsistent with the greater part of Knox's career than placing a stained-glass window to his memory. Painted glass and sculptured work he warred against with the zeal of a Goth. Surely it must be "questionable taste" to commemorate his memory in the very materials he so ruthlessly demolished in all directions. There is only one course to follow in accounting for the taste of the gentlemen who suggested the window in question, by having the Reformer painted full size in the act of throwing a paving-stone at the window erected in the adjoining bay to the memory of the amiable and accomplished Mrs. Hemans.—Yours truly,

Gorey, 17th Sept., 1860. **John Kelly.**

A correspondent complains of *want of water* at Church-road, and with reason. The matter has been already referred to in the Dublin Builder.

Notes of New Works.

Messrs. Kinahan and Co., the extensive spirit and wine merchants of universal note, have recently entered into a contract with Mr. Meade, builder, to the amount of £2,000 or thereabouts, for important works in connection with their establishment in this city. Situated as it is at the junction of two leading thoroughfares, and in immediate proximity with the main artery of traffic, Carlisle-bridge, and seen to a considerable distance down Sackville-street, the improvement may be regarded as one of metropolitan and public character, and consists chiefly in the external decoration of the present front, the erection of a massive granite main cornice and blocking at top of the entire extent of the building, the substitution of handsome plate-glass windows for the antiquated eight-paned sashes, the removal of the present clumsy area railings, the space now occupied being thrown into the street pathway—a great desideratum—and partially covered over by a new open portico. We would forgive this latter feature, but it might be unreasonable to expect that the proprietors should, for public benefit, give up the space, and not require some equivalent. Mr. Caldbeck is the architect.

The houses Nos. 17 and 18, Mary-street have been completely rebuilt, and are being fitted by the proprietor, Mr. G. Tickell, for an extensive furniture and upholstery establishment, under the direction of Mr. Jones, architect; Mr. George Whiteacre, builder. The expenditure will be about £1,500. The shop front will be of a novel and ornate character.

Two detached villa houses are about being built on Pembroke-road (opposite the Botanic Gardens) for Mr. P. Sullivan. Expenditure, £1,650. Messrs. Farrell, architects.

Additions and alterations are being made at the South Dublin Union Workhouse. Mr. James Freeman, builder.

The interior of Little George's Church, in Lower Temple-street, has been re-pewed and newly fitted, at an expense of about £200. Mr. Whiteacre, builder.

Additions are being made to the offices, and improvements to the residence, of B. M. Tabuteau, Esq., Simmonscourt, Donnybrook. Messrs. Farrell, architects; Mr. William Crowe, contractor. Expenditure, £950.

Alterations and additions are being made to the dwelling-house of Greenmount, Drumcondra, the recently purchased property of Jeremiah Perry, Esq., under the direction of Mr. J. J. Lyons, architect.

The alterations to St. Bridget's Church have just been completed, and during their progress, which occupied about five months, the structure was closed. The old gallery, pews, pulpit, reader's desk, have all been removed, and with the exception of the gallery, which has been dispensed with, replaced by new and improved fittings. Tiled floors have been introduced into the aisles and chancel, and the entire of the interior thoroughly remodelled, painted and varnished, &c. The belfry has been altered and a new bell hung therein. Messrs. Barker were the contractors, and are said to have executed their work satisfactorily.

A mansion has just been commenced at Aughentaine, Fivemiletown, Co. Tyrone, for Mr. Thomas R. Browne. Style, Italian, with campanile at south-east, 65 feet in height; 5 reception-rooms; 8 bed and dressing-rooms. Cost, about £6,000. The offices form a separate wing building. Messrs. Farrell, architects.

The Roman Catholic Church of St. Cronin, at Roscrea, originally built after designs by the late W. Deane Butler, architect, is being finished internally, under the directions of his son, Mr. J. S. Butler, architect. The ceiling will be entirely new, with segmental traceried ribs in stained and varnished timber, the spaces between being panelled in stucco. The centre compartment of transept and chancel, and side chapel ceilings will be groined and panelled entirely in stucco. Messrs. Hogan and Son are the general contractors. Expenditure about £1,000.

The church of St. Mary, New Ross, Wexford, is being improved and repaired by the Ecclesiastical Commissioners.

A new school has been commenced upon the property of his Grace the Lord Primate, at Ardtrea, Stewardstown, according to drawings by Mr. Barre, architect. Messrs. Dunn are the contractors.

Plans have been prepared by the same architect and estimates taken for new schools at Tynan, county Armagh, and the buildings are to be commenced immediately. Sir James Stronge and the Primate have subscribed largely to the undertaking.

The new Roman Catholic church of Annacurra (Aughrim, Rathdrum) is now ready for roofing. It has been erected by subscription.

A branch bank and manager's residence is to be built at Ennis by the Provincial Banking Company, according to plans by their architect, Mr. Wm. Murray.

The Wesleyan chapel, Markethill, is being remodelled, including new flooring, seating, pulpit, &c. Mr. Barre, architect.

A design has been furnished by the same architect for a new Wesleyan chapel at Moy, county Tyrone.

The Roman Catholic church at Ballyshannon has been for some time in process of decoration by Messrs. Barff and Co. An apsidal chancel, designed by Mr. M'Carthy, and a high altar in Carrara marble, by Messrs. Farrell, together with stained-glass windows, have also been added.

The restoration of the stable building at the Palace, Armagh, approaches completion. The plan has been completely remodelled, with the addition of dairy, laundry, &c., fitted up with drying and heating apparatus; the stables and harness room, &c., with Musgrave's patent fittings, all under the direction of Mr. Barre, architect.

Ten schoolhouses have been lately built at Ardcarna, in the parish of Roscommon.

A new church has been commenced in Bindon-street, Ennis, facing the new bridge; a new road is also in progress.

The new Wesleyan schools at Armagh are finished, and extensive alterations are contemplated in the chapel adjoining. Mr. Barre, architect.

The consecration of the new church of the Assumption. at Wexford, took place on the 9th ult. As already stated, with full particulars, it is a handsome Gothic edifice, commenced after plans by the late Mr. Pierce, and completed under the direction of Mr. M'Carthy.

Tenders are required by the War Department for works at Military Cemetery, Fermoy.

A Wesleyan Methodist Church for the military at the Curragh camp, and one of the first of its class introduced into this country, has been erected by Mr. Vivian, of the Lucan Iron Works. The skeleton is formed of studding 4in. by 3in. and 4in. by 2in. alternate some two feet apart; sheeted internally with half-inch rough wainscot, canvassed and papered, and covered externally with corrugated and galvanized iron. The roof is an open one – sheeted and stained internally—with slight iron principals, and covered with iron externally. Mr. E. F. Tarleton, architect. There is also a residence for the chaplain similar to the above.

New schools are to be built at Killilea, county Armagh; and a design has been furnished for same by Mr. Barre, architect.

Reviews.

Delamotte's Primer of the Art of Illumination. London: E. and F. N. Spon, Bucklersbury.

Our readers doubtless remember that through the pages of this journal the author's name now before them has been already introduced on two occasions with reference to his "Ancient" and "Modern" Alphabets respectively,—works which from their excellence were at once sufficient, independent of any other efforts, to establish his reputation, and which afforded a guarantee that in his production of any subsequent book he would be equally happy. Thus favourably predisposed we refer to that before us, and find that far from confidence being misplaced, it is fortified by minute penetration into its contents, which evidence an amount of ability in compilation and beauty of manipulation most excellent. It professes to be an "elementary" work, but though undoubtedly such to a certain extent, its pretensions to our mind might soar higher, and an honourable and prominent position in the artist's library should justly be awarded to it. Referring to the frequently unsuccessful efforts of even otherwise skilled artists in the matter of "illumination," the author says that "the secret is they are unacquainted with the fundamental principles of the art;" again that in attempting to copy specimens "they are amazed at finding that after all the pains bestowed on it, their copy has an effect so different from that of the original,". &c. Strange that in this age of progress we should be unacquainted with the manipulatory secrets of those who peopled the earth centuries ago, and have left us their works to improve on and to analyze. Yet so it is in this as in many other branches of art, but with a view of bringing to light the mysteries, Mr. Delamotte's is produced. The contents embrace a history of the characteristics of illumination, practical directions in preparing the colours, gold, &c., and numerous exquisitely handled monograms, initials, the hours of S. Louis, of Henry VII., and of Anne of Brittany, &c The specimens are of the choicest character, and the colouring and gilding handled and blended with the greatest chastity, especially in "the hours of St. Louis." Altogether this is a charming little work, and most practically useful.

Stereoscopic Illustrations of Clonmel, and the surrounding Country, including Abbeys, Castles, and Scenery. With Descriptive Letter-press, and Eighty-two Photographs; royal 4to, fine toned paper. By William Despard Hemphill, M.D., F.R.C.S.I. Dublin: Curry and Co., and Cranfield. London: Bennett. 1860.

It is refreshing to experience that Art has other votaries besides those whose ordinary avocations compel them to worship at her shrine, for, when the pilgrimage is voluntary, it is clearly the more sincere. With aspirations of a loftier character than those generally prevailing with pleasure-seekers during leisure hours, "our amateur author"—by the way an Æsculapian disciple—quitting temporarily his diagnosis and obstetrics, starts on his mission, camera in hand, "to pass agreeably the few physician's holidays," and "illustrate by sun-pictures the beauties within easy access of his home." Such is the avowed purpose of his task, and perfectly has he fulfilled it. We have never seen a work in all respects more exquisitely produced. The stereoscopic views lead us through an extensive district amongst the ruins of "the Rock of Cashel," Cormac's Chapel, the abbeys of Holycross, Ardfinnan, and Cahir, Lismore and Mitchelstown Castles, Athassil Priory, &c., conducting us into every nook and cranny, and developing every detail with strict fidelity. Amongst the many advantages of photography may be enumerated its unerring accuracy and capability of reproduction *ad infinitum*, but by the more recent application of the stereoscope its value is considerably enhanced, the beholder "finding the mirror held up to nature," and lights, shades, distances, and relative proportions as perfectly thrown out as in the original. Thus we may, with such a book as this before us, and without much stretch of imagination, set forth on a tour in search of the beautiful through an extensive district far from home, without stirring from our study chair.

Each set of illustrations is accompanied by descriptive letterpress, and the typography, printed in two colours, is executed in a style highly creditable to the printer, Mr. Peter Roe, of Mabbot-street, upon whose excellence in his branch of art we abstain for *obvious reasons* from dwelling *too* minutely. The binding is likewise admirably and delicately treated; and on the whole Dr. Hemphill may congratulate himself on his production of a book which both internally and externally will bear the strictest scrutiny, and command universal admiration.

Specimens of Mediæval Architecture from Sketches in France and Italy. By William Eden Desfield, architect. London: Day and Son.

THE first six numbers of this work have reached us, each containing *five* proof plates executed in the well-known first-class style of the universally eminent lithographers above named, and at the marvellously moderate price of 3s. 6d. per number. One of the plates would be well worth the money! The pictorial and the practical are most successfully blended, and every detail even in the perspective sketches is clearly developed—a characteristic seldom present in works of this class. We would particularise as a *study*—and if possible for superiority in the manipulation—plate 7, viz, Bayeux Cathedral (west front), and plate 30, Constance Cathedral. The interior of Laon Cathedral (No 30) is also beautifully handled, and a charming subject. The enlarged *morceaux* and the details are most valuable acquisitions, and we doubt not that, when completed, the work will rank amongst the standards.

We are reluctantly compelled to hold over our review of Wilme's Handbook of Mapping, previously alluded to briefly, until next No.

The Midland Great Western Railway branch line to Tuam has been opened for traffic.

It is stated the Roscommon extension line will be opened on the 1st of November. Lords Lucan and Crofton, with the engineer and resident engineer, proceeded by special train a few days since to within two miles of Castlerea.

BRAY.—Referring to the progress of this locality, a correspondent of *Saunders'* says, that the ground is being opened opposite the Marine Hotel, for the purpose of laying down gas-pipes along the Esplanade-road to a considerable distance in the direction of Bray Head. The houses on the shore will be the first to reap the benefit of this, but it is to be hoped that a few gas-lamps will be erected before the winter sets in at certain distances along the shore road; also, that the well constructed dock, formed by the Dublin and Wicklow Railway Company at the mouth of Bray river, is being deepened. This is the first move in the right direction. The next is to cut away the bar of sand and stone which lies directly opposite the mouth of the river. For this purpose a certain sum has been subscribed by gentlemen interested in the welfare of this delightful locality, but the sum stated is totally inadequate to the work to be accomplished. It is proposed to build two parallel walls from the railway bridge to the sea when the bar is cut away, and thus, by sharpening the current of the river, prevent any future accumulation of the same nature. It is of vital importance to the welfare of Bray that no time be lost in carrying out these proposed improvements.

Public examinations in drawing, conducted by the Science and Art Department, will be held on the 3rd inst., at the school of art, Royal Dublin Society.

THE OPERA.

As usual after the lapse of the London season, we *provincial* metropolitans—at least so we are regarded by our Cockney neighbours—eagerly yearned for the advent of the travelling troupe from her Majesty's and the Covent Garden houses, and their announcement is invariably attended with no small amount of commotion and preparation in the vicinity of "the Royal," not to speak of the impetus afforded elsewhere in certain departments which it is not our province to particularise. But seasons affected by "atmospheric" influences and those identified with the "artistic," both seem to lose their equilibrium occasionally, and labour under some variability of temperament; for certain it is that even in the department of Italian opera there is not always present that superlativeness of excellence so manifest as in the engagement just concluded. We dare not—even assuming that we were equal to the task, which in all humility we confess we are *not*, for we feel ourselves as much amateur in the matter of music as a musician would in attempting a dissertation on the constructive arts—enter into a lengthened criticism on the merits of the several artistes who have taken part in the recent series; but we may with some confidencesubmit that the mere mention of such names—without disparagement to the other members of the troupe—as Grisi, Viardot Garcia, Gassier, Mario, Graziani, and Ciampi attest definitely the character of the engagement, and cause criticism "to hide its diminished head." Heretofore when we lived in slower times than we now do—thanks to the genius of progress and his foster brother "steam," they are rapidly paling—lessees believed that something short of a miracle was achieved if they succeeded in inducing *one star* to attempt a *tedious* and *perilous* voyage across the Channel, and the public were satisfied; but now the enterprising caterer "who guides the helm" at the Royal, availing himself of increased facilities, is satisfied with presenting nothing less than "a constellation." Avoiding most scrupulously that hackneyed vocabulary of dramatic terms which some few Press critics seem most *luxuriously* to indulge in, and as it were by a mere transposition of studied phrases, with a few original addenda to make the one notice answer for a season, we may remark that, to our mind, the most successful production of the engagement was the opera of "Don Giovanni," in which all the leaders of the troupe before mentioned sustained the principal characters. With exquisite music, an amusing plot, and such a caste, how otherwise could it be?

Referring to the choral and orchestral arrangement—which by the way seldom occupy the position in public consideration that the labour and skill in their production entitle them to—we must not omit to award Mr Levey his meed of praise, for though nominally acting under a conductor, he, like many others in various positions of life, does the *work*, and the superior officer reaps, if not *all*, at least *too much*, of the credit.

Without much hope of its proving beneficial, we must chime in *our* unqualified disapprobation of the boisterous deities—those enemies to melody and harmony, while rudely aping to court both—who studiously and wantonly disturb the audiences. Indeed the Dublin theatre is becoming notorious for clamour and interruption, but we trust that Mr. Harris will adopt the most resolute means to stop it, and he may rest assured he will be fully sustained by *the Press* and the respectable majority of the community, for whose amusement he so skillfully caters. Foreigners and the inhabitants of the sister countries, already prejudiced against anything "Irish," are not likely to be improved in their sentiments as to our national respectability of character, and we doubt not but that the gossip of "the green room," when such displays take place, is far from being *complimentary*. Appeals to good taste become useless where none of that commodity is forthcoming, and but one alternative is left to the lessee, which for the maintenance of order he should not hesitate to adopt.

OUR ILLUSTRATIONS.

WE present this month a supplementary illustrated sheet, displaying another view of the intended new church of St. Andrew, as designed by Messrs. Lanyon and Lynn, and a ground plan for same building submitted in the competition by Messrs. Deane, Son, and Woodward, whose drawings were considered by the committee third in the order of merit. Also a full page view of the new Roman Catholic Church at Tramore, designed by Mr. M'Carthy, architect.

TO NEWSPAPER EDITORS.—We shall feel much obliged by the conductors of metropolitan and provincial journals, who favour by quotation from our pages to acknowledge such as from "THE *Dublin* BUILDER," our title being very frequently, to our detriment, misrepresented, though we are satisfied only through inadvertence.

NOTICE.

Post-office Orders and Remittances should be made payable to MR. PETER ROE, 42, MABBOT-STREET, DUBLIN.

☞ *NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the* DUBLIN BUILDER." *All other Communications should be addressed to the "Proprietor and Editor,"* 17, LOWER GARDINER-STREET.

BUILDERS' IRONMONGERY, AT REDUCED PRICES.

THOMAS HENSHAW & CO.,

5, CHRIST CHURCH PLACE,

BEG to call attention to their extensive, varied, and well-selected Stock of Ironmongery in all its different branches. It consists of Parlour, Drawing-room, and Bed-room Grates; Kitchen Ranges, Cottage Ranges, Sash Weights; Iron Rim, Mortise, and Stock Locks; Hinges of all descriptions; Wrought and Cut Nails, Eave Gutters, Down Pipes and Fittings, Metal Skylights, Ventilating Bricks; Cast-iron Chimney-pieces, with and without Grates; Rabbit Traps, Fox Traps, Galvanized Wire Netting, Fencing Wire, Sheet and Perforated Zinc, Sink Traps, Furnace Doors and Frames, Hot Air and Plain Stoves. Also on Sale, Saunders' Patent Cooking Range, *the* most economical Cooking Apparatus of the day.

Manufacturing and General Ironmongers and Tool Warehouse—81, MIDDLE ABBEY-STREET.

Spade, Shovel, and Tool Works—CLONSKEAGH.

Agents for Perry's Patent Fire-proof Safes; quality considered, they are *the* cheapest in the market. Builders are invited to inspect our Stock previous to purchasing.

5, CHRIST CHURCH PLACE, DUBLIN.

FORREST AND BARR,

PORT DUNDAS ENGINE WORKS, GLASGOW,

MAKERS of Planing, Sawing, and Moulding Machines of the most improved constructions. Patent Safety Derrick Cranes, Portable Steam Hoists, and all kinds of Cranes, Hoisting Machinery, and Builders' Plant. High-pressure and Condensing Steam Engines, and Gearing of every description, &c., &c.

Catalogue of Prices and Designs, &c., and further information, to be had on application to WILLIAM TURNER, Oxmantown Foundry, Dublin, Agent.

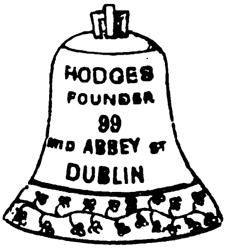
London and Paris Great Exhibitions



Prize Medal Bells.

IBBOTSON's IMPROVED OAK STAIN, for imparting to New Deal the appearance of Oak, and to New Oak the appearance of Antiquity.

It is about half the expense of paint, and is easily applied with a brush. Being an Oil Stain, it has the important advantage over all other stains of being impervious to wet. It produces a bright gloss, but if a high polish is required, the proper varnish can be applied. It requires no size or previous preparation of the wood.

The Stain (with the proper varnish, if required), of three shades—Light, Middle, and Dark—is sold in Bottles at 6d., 1s., and 2s. each, or by the Gallon, at 10s.

SOLE AGENTS—BOILEAU AND BOYD,
(Late John George Boileau and Co., Mary's-abbey)
92, BRIDE-STREET, DUBLIN.

The Dublin Builder.

Vol. II.—No. 23.

THE TAYLOR PRIZES—FIRST DISTRIBUTION.

FOR some days past the announcement that there were being exhibited at the Statue Gallery of the Royal Dublin Society a collection of works of art, sent in competition for the Taylor prizes, attracted thither some few individuals—fewer indeed than desirable — ourselves amongst the rest. Before we proceed to notice these works, we present a brief outline of the circumstances connected with this exhibition, as stated in the Society's circulars:—

"By the will of George Archibald Taylor, Esq., late of Mespil-parade, Dublin, the sum of £2,000 was placed at the disposal of his executors for the promotion of art in Ireland; and it has been resolved to establish a perpetual endowment for the encouragement of students in the fine arts, according to the terms thus recited:—

"The general management to be entrusted, in conjunction with the executors and trustees of the will for the time being, to the Royal Dublin Society, as joint trustees.

"The dividends to be applied, after providing for necessary expenses, to the endowment of scholarships and money prizes, open to all students of art, of either sex, who shall have attended for two years at least a school of art in Ireland, or who, being of Irish birth, shall have attended for the like period a school of art in Great Britain or elsewhere, and who shall produce at the exhibition hereinafter mentioned works of art displaying conspicuous merit or high promise of future excellence.

"An annual exhibition to be held in Dublin of the works of art which shall be sent in for competition.

"The proper subjects for competition to be determined by the trustees.

"The amount of the money prizes to be in the discretion of the trustees, having regard to merit; and when high artistic talent shall be manifested, one or more scholarships (to be called the Taylor Scholarship) of £20 or upwards may be awarded, which may be held for a second and third year, provided the student shall produce in each year a work of sufficient merit.

"The prizes and scholarships to be withheld in whole or in part, when no adequate positive merit exhibited; and the amount so reserved added to the principal of the fund.

"The prizes and scholarships will be awarded upon the report of the judges, to be chosen respectively from the Council of the Royal Dublin Society, the Royal Hibernian Academy, and the Governors and Guardians of the National Gallery of Ireland, with certain provisions in case of either failing to fulfil its part."

The sizes of the pictures and other particulars are then specified.

Clause No. 13 says that,

"Candidates for scholarships must be prepared to satisfy the trustees of their intention to devote themselves to art as a profession.

"The trustees do not prescribe the precise subjects of the prize works, discrimination in the choice of a subject being regarded as. in some measure, a mark of artistic capability; neither do they put any limitation on the age of the competitors. But in the adjudication every circumstance will be considered with reference to the prime objects of the endowment, namely, the encouragement of the schools of art in Ireland, and the development of Irish talent; and the trustees reserve to themselves the absolute right of determining whether the party competing be strictly *a student*, and in other respects comes within the intention of the trust.

"Communications on the subject of the Taylor Prizes and Scholarships may be addressed to Ralph B. Brunker, Solicitor to the executors, 31, York-street, Dublin; or to William Edward Steele, Esq., M.B., Assistant Secretary to the Royal Dublin Society."

Appropos to these provisions we find the following syllabus issued for the year 1860:—

1. For the best picture in oil colours, the subject historical or familiar	£10
2. For the best landscape in oil colours	10
3. For the best composition in sculpture	10
4. For the best water colour Drawing (Subject or Landscape	10
5. For the best architectural drawing (elevation in perspective of some known building or a design) ...	7

It will be seen by the above, that all subjects submitted in competition must be *original*, but we regret that the number of pupils who have entered the lists is very limited, and moreover think—from the degree of merit displayed—that the adjudicators have exercised a wise discretion in withholding the scholarship and one of the prizes. Facing the entrance doorway in the ante room of the gallery is a recumbent female figure, cast from a model by Miss Jane Morgan, of Cork, and awarded a medal in the School of Art in that city. To this work a Taylor prize has been decreed. The pose of the figure, and the disposition of the drapery, specially entitle it to much commendation, and suggest a reasonable inference that at no distant date the artist will occupy a position amongst the many notables in art produced in that city. Another prize is bestowed on Miss Annie C. White's excellently drawn and tinted perspective view of west nave and aisles of St. Patrick's Cathedral, prior to Mr. Guinness' restorative works being commenced. We understand that this lady has projected the drawing in question from actual measurement,—the difficulty of which task must be appreciated, but *the fact* is proclaimed by the accuracy with which every feature and moulding, every crumbling detail is delineated. We should be disposed to wish that this lady would pursue the art to a profession, and institute an order of "lady architects." A third prize is awarded to Mr. M'Evoy's picture—a forest landscape, in oils, a meritorious work for a student, but somewhat too cold and stiff in style. Amongst the *non*-premiated works we find a charming picture,—with certain restrictions—in oils, by Miss Almont, a view near Stillorgan, and to our minds, without drawing invidious comparisons with others, at least *entitled to a prize*. The lights and shades are effectively brought out, the exuberant foliage of the trees most naturally depicted, and with a vigour and warmth peculiarly commendable for a young artist. We must, however, with all due regard for the artist's license, take exception to the ultra-blue tint of the smoke from the cottage chimney, brighter than the *too* bright sky in the background. Nevertheless the artist has much reason to hope for congratulation upon the merits of her work. Mr. Crowley has two pictures strikingly different in style,—the one not altogether an unsuccessful imitation of the Belgian school; the other, viz., the harbour of Wicklow, displaying a good deal of truthful treatment and picturesque grouping. We would say to this artist certainly "try again" and *again*. Mr. Maine's water colour picture (a portrait) of an aged gardener in a sitting and pensive posture, with his dog asleep beneath his chair, is a meritorious work in its line. A group of fruit and flowers by another competitor displays too gaudy colouring, and cannot have been copied from nature. There are two other pictures—do they merit the name? —one by a Dublin, the other by a Cork student; but as they do not even approach to passable mediocrity, the authors' names are best committed to oblivion.

THE ROYAL COMMISSIONER AND THE WATER SUPPLY.

THE recently published report of Mr. Hawkshaw, C.E., after reciting the objects and particulars of the enquiry which had been called on to institute, the sources of the present supply, the state of the city basins, the various suggestions for an improved supply submitted during the inquiry, the evidence connected therewith (and already published *in extenso* in the DUBLIN BUILDER), proceeds to point out the River Vartry scheme before all others, in the following terms:—

"The water of the Vartry is *wholly unobjectionable*. It is practically equal to that of Kippure, as it respects softness and freedom from impurity, and possesses the great advantage of being generally colourless.

"There is a very eligible site for a reservoir, and the collecting ground is sufficient in extent for the requisite supply to the population.

"It is more costly than the other schemes; but, on the other hand it possesses an advantage which will compensate for the greater cost, viz., that of admitting of a ready supply of water to the large population on the coast between Dublin and Bray—a matter of great importance when it is considered that the extension of all the best buildings is in that direction.

"I have found, during my investigation of this subject, that, although numerous sources of supply had been suggested, yet the water of many of them. however suitable in other respects, was more or less deeply coloured. This I have already intimated.

“It arises from the circumstance that the granite mountains from which the Liffey and Dodder derive their origin are not found naked and exposed, but are usually covered with a thick coating of peat.

“It has appeared to me in determining this important question, upon which the health and comfort of a large and growing population will greatly, and most probably for a long period of time, depend, that all water highly coloured with peat is thereby rendered ineligible, provided that water free from such objection and otherwise suitable can be obtained.

“A mistake on this point would be more seriously felt by the inhabitants of Dublin, because, however bad the water supplied to that city has hitherto been in other respects, it is ordinarily colourless.

“Mr. Bateman, who advocated the Kippure scheme, believes he could, by a process of separation, render the Kippure water sufficiently free from colour.

“Mr. Hawksley, who examined this district on many occasions, and who reported on it in 1859, differs from this view, and concludes, that unless chemical agents were used, which would add enormously to the cost, the water, if taken from the Kippure, would when supplied to the citizens of Dublin, be a brown water.

“It appears to have been this among other considerations which induced Messrs. Hawksley and Neville to seek a supply lower down the Liffey, and to adopt Coyford, where the water, by travelling several miles exposed to sun and air, and by mixing on its route with some limestone water, undoubtedly loses some of its colour, and approximates more nearly to that great desideratum, a colourless water.

“Possibly some improvement could be effected in the colour of the Kippure water by taking in that of the River Brittas; but after long and patient consideration, I have arrived at the conclusion that, if on no other ground, yet on the score of colour, it would not be advisable to adopt either Kippure, Poulaphuca, or the Dodder, as a source of supply.

“The waters of Coyford would probably, when supplied to the consumers, be nearly white, and though somewhat inferior in point of hardness, might, I think, in the absence of a better source, afford an eligible supply to the city of Dublin. But it appears to me that in selecting an article so important to the health and comfort as water, it is an imperative duty to choose the best, if that can be obtained at a cost within the means of the corporation.

“The water of the Vartry is, in my judgment, *so much superior to all the other waters, the quality of which has been discussed*, as to induce me to prefer it; and in coming to this conclusion, I have weighed, as well as I am able, every point that should enter into consideration in coming to so important a decision.

“No new source of water supply can be obtained for the city of Dublin without encountering difficulties of some sort.

“Were it determined to take water from the head of the Liffey at Kippure, it would involve an interference real and imaginary with a river between sixty and seventy miles in length, studded with mills, skirted by important demesnes, and flowing at last through the harbour of Dublin.

“The Poulaphuca project would involve almost an equal amount of interference with the rights of property.

“The Coyford scheme, if carried out with a compensation reservoir, would still involve many similar questions, and it would not escape these difficulties if it dispensed with a compensation reservoir.

“And the river Dodder, though only twelve miles in length from near the summit to its junction with the Liffey, has numerous mills on its course, and there are many more on the city watercourse, and on the Earl of Meath's watercourse. This river also empties itself into Dublin harbour.

“Though the river Vartry is comparatively short, the Vartry scheme *is not wholly free from objections of this kind.* The river flows through Wicklow harbour it passes through a place of considerable beauty called the ‘Devil's Glen.’ But the mills upon it compared with the Liffey and the Dodder are few in number and small in value.

“These questions have been considered in arriving at the relative cost of the schemes.

“The estimates given by different individuals of their various projects did not admit of accurate comparison.

“To aid me in my investigation, I requested Messrs. Hawksley and Neville to devise a competent plan for taking water from the Vartry, and also to furnish me with comparative estimates of the cost of obtaining supplies of water by means of those projects, which appeared to me, after reviewing the whole question, to be the most eligible, viz., the Dodder, Kippure, Coyford, and the Vartry. These estimates are made out as nearly as was practicable on the same scale of prices. The following is the result of their detailed investigation:—

		Estimated Daily Supply.	Cost.	
		Gallons	£	£
1	Dodder including Filters	10,000,000	234.668	
	Annual cost of filtration, capitalized		12.500	
				247,168
2	Ballysmuttan or Kippure, including Filters ..	12,000,000	233,579	
	Annual cost of filtration, capitalized		15,000	
				248,579
3	Coyford, with compensation reservoir at Kippure, including Filters	12,000,000	210,307	
	Annual cost of filtration, capitalized		15,000	
				225,307
4	Vartry (without Filters)	12,000,000		295,992

“The water from the Vartry, without filtration, *will be equal in quality, and superior in colour, to any of the others with filtration*, and therefore the annual cost of that process, which if capitalised would amount to £12,500 on the Dodder scheme, and £15,000 on the Ballysmuttan and Coyford schemes, should, for purposes of comparison with the cost of the Vartry scheme, he added, as it has been to the first three estimates respectively.

“And further against the increased cost of the Vartry scheme must be placed the revenue that would accrue to that project from the greater facility it would afford of supplying the population between Dublin and Bray.

“In conclusion, the results I have arrived at are,

“1. That the state of the present supply of water to the city of Dublin is bad.

“2. That there is urgent need of an improved supply.

“3. That the best source from which an improved supply can be obtained is the River Vartry.”

After some discussion upon the resolution that the report be received and adopted, the question was put by the Lord Mayor, and carried unanimously amidst applause.

Thus is solved the *vexata quæstio* of the water supply of Dublin, one of the most memorable and protracted that ever occupied the consideration of a municipal body!

Ireland, said to be the slowest of civilized countries, now boasts of the swiftest steamers in the world—the *Ulster*, *Connaught*, and *Leinster*, plying between Kingstown and Holyhead. Each are about 350 feet in length, and make the voyage (68 miles) in an average period of 3 hours 15 minutes. The enterprise of the City of Dublin Steam-packet and North-western Railway Companies respectively, in providing the accelerated communication, cannot be too highly appreciated; and when the *Munster* is on the line the system will be complete. We *believe* that *we* live in an age of wonder, but what if our children's steamers should accomplish the journey in *half* the time, as we have done in that of *our* fathers? What a revolution in naval architecture is sure to follow the feat so far accomplished! How posterity will smile at our Himalayas and Great Britains! and regard them, as we in our turn have others, as “cumbersome tubs!”

We have the authority of Mr. George Francis Train, the patentee, for stating, that in about six weeks the first street railway will be opened in London. The route will be along Victoria-street, Westminster, extending from the Broad Sanctuary, near the new Westminster Hotel, to the Vauxhall-bridge Road. A car of somewhat similar pattern to those at Birkenhead, is being built by the Railway Carriage Company of Birmingham.

The new Victoria station of the London, Brighton, and South Coast Railway situated at Pimlico, about 400 yards from Buckingham Palace, is now open, and the largest of any of the metropolitan termini.

A new railway has been opened in Turkey, between Rustenjie and Tchernavoda.

A new Roman Catholic church, forming a portion of an extensive pile of buildings erected at Liverpool, from designs by Mr. W. Pugin, architect, has been opened for divine service. It is said to be, with one exception, the best specimen of ecclesiastical architecture in the town.

The new machine for emptying the drains of Paris, considered one of the wonders of the age, came into use recently, and attracted an immense crowd to see it perform its work. The city of Paris had deputed its three chief engineers to report upon its merits, and success was pronounced complete. The drain, which by this new method was emptied in broad daylight, was one containing 80,000 litres. The principle of vacuum is employed, and it is decided that henceforth all great operations of the kind are to be conducted on the same system. The operation, unsavoury as it appears, was considered of so much interest to the health, cleanliness, and convenience of all large cities, that it was treated as a solemnity, and the court-yard of the Caserne de l'Omeine, where it took place, was filled with all the notabilities of the city—journalists, doctors, economists, and legislators.

A "DORMANT" INSTITUTE.

THE activity already manifested at the earliest dawn of the Session of 1860-61 amongst the respective scientific and artistic bodies of the kingdom (metropolitan and provincial), reminds us forcibly of the invincible drowsiness of *one* of the fraternity, who, while others are "up and stirring"—fully refreshed after a long interval of repose—still tenaciously grasps Morpheus' mantle, and yawns for prolonged oblivion. To disturb the slumbers of the weary is an ungracious act, but we must plead guilty to the imputation if, in the performance of a public duty, we take permission—first *gently*, and, should it prove ineffectual, afterwards *persuasively* and *energetically*—to remind our somniferous friend that it is *time* for him "to rise also." As even amongst children sprung from the same parents the greatest dissimilarity of dispositions, tastes, and opinions are observable, so is a marked contrast presented by this member of a family, having wide and influential connexions, towards his relatives, either at home or abroad. Precept, moderately applied, or even the forcible argument of practical example, have as yet proved unavailing in diverting his taste from its slothful channel; nevertheless we are far from pronouncing his disease totally incurable, however great may be the amount of skill and labour necessary to bring about the desired end. Drawing aside, however, the curtain that veils our sleeper enjoying his *bon repos*, and directing the bright rays of public opinion full upon his oblivious countenance, moreover divesting ourselves of metaphoric garments, we come, in plain terms, to ask the ARCHITECTS OF IRELAND—why is it that *they alone* of their fellows in the United Kingdom are unrepresented by an *active* conservator of their interests? and why, when made sensible of the fact, do they not adopt the proper course to ensure one? Dublin is *styled* "the second city in her Majesty's dominions," and not unreasonably complimented on "the architecture of her public buildings"—the architects of Ireland have invariably been distinguished as a body for their attainments, and many members of the fraternity have, both at home and on foreign ground, fought many a brave battle for priority, not unfrequently bearing away the palm gloriously; yet withal, individual supremacy seems to be the engrossing consideration, and the members of a gentlemanly profession, presumed to possess more dignified aspirations than mere Mammon-loving materialities, tacitly writhe under the stigma, that their *common* interests are entirely superseded by their *personal*. In glancing at the past history of a body styled "The Royal Institute of Architects in Ireland," we desire specially to record, that we speak, on *principle*, for the well-being of the profession and the advancement of an art with which our own most earnest aspirations are associated, and not with the desire of reflecting on its members individually, most of whom are personal friends, and for *all* of whom we entertain, as kindred craftsmen, more or less regard. This explanation we deem necessary for reasons we need not *now* detail, but which will be readily understood, and we trust appreciated, by those to whom it is directed. The institute in question was first formed in 1839 by a few of the—*then comparatively* few—practising professionals, with the late Sir Richard Morrison as president, and, with some intermissions, continued its meetings until 1857, when, notwithstanding the fact that the financial state of affairs was perfectly solvent—a sum exceeding ONE HUNDRED POUNDS being to the credit of the body in the public funds—it seemed to become desirable (in whose opinion or for what reason we know not) to suspend the institute, and sell the material property, for the purpose of reimbursing the treasurer some £30 or thereabouts, due to him for payments made. Rather startling this; but until a *general* meeting of *all* the members be convened, to wind up the affairs *in toto*, and the officials render a comprehensive account of their stewardship, we cannot recognise the institute as positively defunct, but only revelling in that obliviousness for which it ever maintained a predisposition. In plain truth and as a matter of *business*, may we ask, is the course suggested one that those entrusted with the conduct of the affairs of the institute ought to hesitate to adopt, either for *their own satisfaction* or that of the members and the profession generally? Three sessions have passed by, yet matters remain in *statu quo;* and if the "dormant institute" is determined to defy all remedial measures, it ought at least have *the honour* to awake for a moment and *say so*, that a successor, more energetic and competent, might be appointed to fill the post. We confess to a regard for old associations, and we should much prefer seeing the "parent" (are we complimentary in the term?) institute *redivivus*, than find the place it should occupy in the possession of a stranger. Yet this result we must expect, and acting as the mouthpiece of the profession, in which there remains yet a sufficiency of youthful blood and independent principle, we pronounce the warning.

Strange to an anomaly is it that in this state of things individual members positively sympathise with each other on the fact, that the profession in Ireland has no fitting representative, and exclaim with wonder ever and anon, as to the why and wherefore, the irreconcileable inconsistency, &c. *Action*, not *talk*, ought to be the banner under which every zealous worker should aspire to move; but unfortunately in the elements of our national composition the balance is materially in favour of the latter commodity. "Time enough" is a somewhat dangerous principle to depend on, yet we must remind our readers that "there is a time for everything," and if the "dormant institute" should still remain proof to our *gentle* persuasions, we shall not hesitate to appeal to the alternative of "energetic treatment." Elsewhere in this journal are to be found reports of the proceedings of the various scientific and artistic bodies of the kingdom, and well may the *Architects of Ireland* "hide *their* diminished heads," in comparing the position of their brethren elsewhere with *their own*. Let us hope, however, that in our next "bulletin" we may have the gratification of recording even the *partial* awakening of the patient from his *coma* state!

ARCHITECTURAL SOCIETY, LIVERPOOL.

ADDRESS OF THE PRESIDENT, JAMES M. HAY ESQ., ON THE OPENING OF THE SESSION, 1860.

GENTLEMEN,—The study and advanced knowledge of architecture have ever been confined to a small portion of the community, and it is not wonderful that it should be so; for when to master even a rudimentary knowledge of the art requires so much time and patience, how much more does it not require to be able to judge of its excellences or its shortcomings, to point out its faults or suggest their improvement? It is this small portion of the community, this cultivated few, to whom the architect in all his highest efforts addresses himself. They are the leaders of taste, and are the tribunal before which he stands or falls, whose approval he covets, whose censure he would avoid. Of late years the study of architecture has been greatly promoted. Men of the highest literary attainments have enlisted in its service, and devoted their energies to the elucidation of its principles, both in works of deep metaphysical inquiry and those of a more popular form. A greater general interest has been established. This and other architectural societies are partly the result of that interest, and react in a further extension of it. The number of architects has increased in much larger proportion than the population; nor am I of those who regard this as a misfortune; on the contrary, it is my conviction that there are still too few, and that much of what passes current as architecture (where every canon of pure taste and sound construction is violated) is where no architect has been employed. The works in the vernacular style of the present day have been visited with deserved ridicule and the severest criticism, but others beside the profession are chargeable with their faults.

It is somewhat difficult to leap forward a hundred years and imagine what posterity will say of the arts in the year 1860, or to divine its critical opinion of the architecture of our own time. Still we do form an opinion, which, though necessarily partial and conjectural, may yet be worth while to analyse and record.

We can look back upon the history of our art, and trace it from its infancy; we can watch it step by step as it gradually advanced towards comparative perfection and then rapidly declined; how it sprung up in other lands and pursued a similar rise and fall, or became mingled with other streams, and then again bursting out and spreading into various ramifications, enjoying a greater or less glorious period of existence. But we still observe it in every case obedient to the universal law of progress and decline. It is interesting to embrace the whole in one comprehensive view; it is interesting to examine the leading styles and the various secondary and tertiary ones proceeding therefrom, to analyse their elements and their various relationships; it is not only interesting, it is a portion of knowledge indispensable to the architect, for it is the very groundwork of his art, and essentially necessary to a thorough mastery of its principles.

These remarks have been suggested to my mind by a vivid recollection of Mr. Huggins's chart of architectural styles exhibited here towards the close of last session. The idea was a happy one, of so embodying the entire history of our art, and presenting it to the student at a glance. Its invention cannot but be considered as exceedingly well timed; for if published it must yield valuable assistance in the study (now of so much importance) of the development and relationship of the various styles of architecture in all times and countries—and not only among the profession, but also among the public at large—and assist in rendering architecture a feature of popular education. It is to be hoped that Mr. Huggins will have it published in such a manner that a copy may be had by every member of the profession, and also suspended on the walls of every school and seminary in the kingdom.

The exclusive study of one style will induce a preference for that style, and the practical result will be a servile copyism alike degrading to the artists and injurious to the art. It is only the mind which is thoroughly imbued with the principles and characteristics of all styles, and which draws its inspiration from every source, that is capable of producing great and original works. His genius is unfettered, for his materials are unlimited; his invention is more active, for new combinations suggest themselves at every step and become moulded and recast in forms of beauty never before dreamt of. Though familiar with all precedent, he is less bound by it, and sees the same end accomplished in a variety of ways, resulting in various forms of beauty; his ingenuity is thereby stimulated, and his own productions are more likely to exhibit the most excellent qualities of ancient work.

If the prevalence of the styles practised in the present day—the classic or Italian and Gothic, with their various ramifiations—be the result of fashion, we may safely predict for them a transient or evanescent existence. But the revival of these styles rests upon a broader and deeper foundation. They each of them exhibit principles or qualities which we dare not sacrifice, and must not lose sight of. While the battle of the styles goes on, the great majority of architects practise in both styles, making their selection according to the object of the building, the nature of the site, or the kind of materials at command. We may consider this as a mark of progress, for it indicates a thinking out of the subject from the very beginning. An architect may now draw his inspiration from sources as wide apart as the poles, and introduce forms and features in his designs for which no examples exist and no precedent can be cited. This is also a decided mark of progress, for it indicates a consciousness of art power which,

> " Without breaking covenant with the mighty dead,"

but estimating at their proper value ancient examples, is yet ready to avow its independence and assert its superiority. This practical freedom is perceptibly changing the expression of our architecture, and giving it a character of its own. Hence the difficulty of giving a name to the style of certain modern structures beyond indicating their parentage. This is considerably in advance of the period when it was thought a high eulogium to say that this building was exceedingly fine, for the portico was an exact copy of one in Rome, or that that church was a splendid example of modern Gothic, for all the details were taken from York Minster. No true architect is now desirous of his work being mistaken for that of the 13th or 14th century, or any other period of past history, but rather that it should be the product and bear the impress of his own mind.

Liverpool possesses buildings recently erected, or still in course of erection, which exhibit the justice of these remarks. In most of these the classic element is predominant, while a Gothic spirit animates and pervades the whole. These buildings are valuable acquisitions to the town, and will remain as landmarks in the advancing tide of architectural development. London and other cities and towns have numerous examples of the same tone and tendency—examples in which we can imagine their authors saying to themselves, " Let us throw style entirely aside; let us design this building according to the principles of art, refusing to admit any one style having exclusive occupation of our mind at the time."

I do not overlook the importance of travel, whether to the student, the draftsman, or the busy practitioner. All men should travel, were it for no more than to amuse themselves; but to the architect this amusement may be combined with sound architectural instruction.

During the recess I availed myself of the opportunity of having a few weeks' tour on the continent; and next to a ramble amongst the villages and hamlets of our own land, there is nothing so invigorating to mind and body, or tends so much to restore that equilibrium of the system as foreign travel. To see with your own eyes those monuments of architectural genius which in past years have been your study, is always a source of enjoyment. Around them are associated some of the happiest moments of your life—those moments and that period when your love of art was just awakening in the soul and began to glow with intensest enthusiasm. You walk around them with boyish wonder, and seem to renew an intimacy as with an old friend. Much is familiar, much more has all the freshness of novelty. Discarding or correcting false impressions, you are no less gratified in finding out that others which you had previously formed are fully borne out and corroborated by what you see. But the value of travel consists not so much in actual seeing as in what is suggested. The mind is kept in a state of active excitement; ideas follow each other with rapidity, but are evanescent, and should be jotted down as they arise, otherwise they are lost. My excursion included the tour of Mont Blanc and a small portion of Switzerland, a country which was entirely new to me.

With most young architects the desire is to see the antiquities of Greece and Rome or the mediæval cities of the continent. This is natural, for there are to be found the finest examples of architectural art; but let them not forget to visit mountain scenery whenever it is in their power to do so. Ruskin somewhere says that the brains of the architect are too much bricked up by a continual residence in large cities, and that he should repair to the mountains to give them air, and health, and vigour. This repeatedly occurred to my mind in traversing some of those wild mountain passes, where, pausing in the midst of awful solitude and profoundest silence, the whole soul glowing with indescribable emotion, you feel isolated, alone with the Eternal and the Infinite. Architectural lessons are here taught on the grandest scale. How simple and yet how varied those mountains appear! with what an idea of eternal fixedness they strike the beholder, and yet how animated is the picture as they seem to play at hide and seek with the floating clouds and long drawn sunbeams!

The architect is frequently advised to go to nature to study; but this, I apprehend, is generally considered to mean the vegetable and floral portion of her domains, where, instead of thoughtlessly repeating the work of past artists, he may study the leaf and flower for himself. Let him not limit his interpretation of the advice to so circumscribed a sphere: to the ardent and faithful student of architecture, nature in these Alpine regions has lessons of higher importance to unfold. It is here that he is irresistibly impressed with the elements required to form a grand architectural work—simplicity, boldness of outline, composition, and grouping; an overpowering breadth of light and shade; daring contrast in form, structure, and colour; and, pervading all, an expression of eternal repose.

The young student is apt to spend too much time in acquiring a knowledge of mere detail, and the practical architect in its application, forgetful of more important elements. The purest detail will not atone for the absence of these, and their presence alone will stamp a work with genius and power. There are works in even the most debased styles arresting attention and proclaiming this fact. Detail is but the feathers on the butterfly's wing, the foliage on the tree, or the mossy covering on the mountain side; it is that artistic stippling which gives emphasis in some parts and reduces it in others; it bears a certain relationship to the general conception of the work as a whole, but is the last, not the first, consideration in architectural design.

The approaching completion and inauguration of the Free Library and Museum are naturally occupying much of public attention. It must be a source of great gratification to Mr. William Brown that he will so soon be in a position to hand over to the authorities and public of Liverpool this enduring monument of his generosity—a generosity that is appreciated by every intelligent mind, for its fruits will be experienced by all classes of the community in the present as well as in future generations. The gallery to be set apart for scientific and mechanical inventions has a peculiar interest for the members of this society, and it, along with the architectural department of the library, so much indebted for its valuable contents to the zealous and persevering efforts of the chairman, Mr. Picton, will become an attractive resort for both our students and professional members.

I trust that the session we have now commenced will be a useful and prosperous one. The history of architecture is closely allied to the history of the world and the progress of civilisation; and the architect has no time to fritter away in pursuits which have not a direct or indirect bearing on his profession.

THE *AGRICULTURAL REVIEW* ON DUBLIN STREET ARCHITECTURE.

In a recent number of the abovenamed cotemporary we find—after a complimentary notice of this journal, for which we feel obliged—the following remarks:—

" As a rule, the fronts of our houses have not width enough for any really effective design. Let one of them be done up ever so well, it only looks like one side of an overgrown mantelpiece stuck against a row of brick houses. It is too narrow for its height, or too high for its width, or rather, narrowness, and the eye wanders literally in quest of the fabric to which it belongs. But, instead of finding any remainder, the visual organ conveys to the brain the image of the half of some other unfinished design. No. 10 presents a solid, massive front, as if built of granite, from top to bottom; No. 11 grins at you, all in brick; whilst No. 9 and No. 12 are on each side, as if they had belonged to each other originally, but had lost partnership in some fantastic midnight dance, and had been disfigured and disguised somewhat merely by the application of pigments of different hues. So on, one might go, noting how the masses of building might be grouped and laid out, as a landscape gardener would do with a piece of ground; but finding that all the owners and artificers had put their heads together, to see how best they could steer clear of doing their work in harmony, or for a common purpose."

ART IN ENGLAND.

It has been a settled thing this many a year that the English people are deficient in the aptitude for art. The French, the Italians, the Germans, half kindred as they are, assume a soaring superiority over us in this respect, and have long solaced themselves with the thought, which enabled them to grant us more freely our due on other points. The genius of England was purely practical, they declared: steam, bridge-building, railroads, mechanism, and money-making in all its branches was our province; but in the region of art, in the delicate sense of the beautiful and the graceful, she was nought—a barbarian, a Caliban. We were the gnomes, in fact, of humanity, condemned to work in the dark depths of the earth—the continental nations the sylphs, floating in the rare ætherial atmosphere of beautiful conceptions and graceful fancies. There was superficial evidence enough of this theory to convince even ourselves of the truth of this humiliating theory. We had but to look around us at our furniture, at our daily implements, at our costume, at our buildings, at our monuments, to be driven in candour to the confession that what the English artizan produced might be solid, sound. useful. strong, cheap. even mechanically neat and perfect in its adaptation to the service in view, but that it was disgraced with the stamp of unmistakeable ugliness. Take, for instance, our pottery. None could beat us in the manufacture of the material ware; but what nightmare phantoms were the shapes it was moulded into—what distorted caricatures were designed upon it! Even Wedgewood employing Flaxman to adorn dinner and breakfast services with his pure and classical conceptions failed to shake the reign of the hideous over our ceramic manufactures. Squat and bloated jugs, terribly suggesting the obesity of beer drinkers, graceless dishes blurred with the insane "willow pattern," were all hugged with maternal fondness to the national bosom. Through the whole range of practical art the same characteristic research after the unpleasing was manifest. Foreigners laughed at our want of taste, and we had to join in the laugh with the best grace we could, and pay dearly for our elegance as a foreign import.

It was certainly puzzling how this should be. Had the inhabitants of these particular islands been deprived by a wholesale *lusus naturæ* of those finer perceptions which add a crowning grace to civilized life? Was there something in our insular atmosphere that cretinised us in respect to art, and shut up the sense of beauty in utter numbness? Having a national muster-roll of great names, on which figure those of Wren, Reynolds, Gainsborough, Hogarth, Leslie, Turner, Maclise, Landseer, it would be difficult to acquiesce in this position. The question is, whether the aptitude for art is geographically distributed. as are classes of plants and animals, and if the British soil and climate be one in which it refuses to flourish. Facts very emphatically answer no in the instances referred to and numberless others; and more recent manifestations are at hand to show that the Englishman is not afflicted with that defective organisation which must shut him out inevitably from excellence in Art.

Gœthe wisely said, "Take care of the beautiful—the useful will take care of itself." In this country it is our practice to let everything take care of itself; and we have furnished the most admirable illustration of the truth of the great German's saying, for the useful alone has flourished with us. But Art must be fostered by timely and enlightened patronage; it must be tended, watched, and sunny gaps made for it, or it will not shoot up and smile on us with its luxuriance. Such patronage among foreign nations has been constantly granted to Art by the State, and in Catholic countries by the Church; and the prevalence of beautiful objects has educated the taste of the people at large. For years these influences have been at work, and hence the supposed natural superiority of continental nations in æsthetical matters. On the contrary, the stern Puritan spirit of our Protestantism and our republican jealousy of State interference, have shut out both of these sheltering and vivifying agents, and left the encouragement of artistic excellence to the precarious patronage of individuals. Thanks to the wealth and taste of our aristocracy, a general blight has not nipped the growth of all Art in this country; but until quite recently our art treasures have been shut up from the public view. With the exception of a rare church, a rarer old cathedral, and, rarest of all, an occasional statue, the native Briton, except in his cultivated fields and natural scenery, has been surrounded by unsightly objects. No general appreciation of what is truthful and beautiful in art therefore has been inculcated in the mass of the people, and hence they have been stigmatised with the absence of the very sense of the excellent.

Tardily these truths have been recognised, and we have roused ourselves from apathy as a nation towards the careful encouragement of Art and the education of the public taste. The State has been empowered to exert itself to some extent in this direction—not with much liberality perhaps, but what it has done has been entrusted to hands who have worked strenuously, and they have been much assisted by private munificence. The Government Schools of Art, having their head-quarters and directing momentum at the South Kensington Museum, have already effected a little revolution in the character of our manufactures; and if we may implicitly trust the evidence of the directors of this new department of the executive before a Select Committee of the House, which it is fair to say is corroborated by the testimony even of foreigners, we are bidding fair to outrival the Continent in its boasted special aptitude for works of art. In 1859, M. Roudot was commissioned by the Chamber of Commerce of Lyons to see what was likely to be the result of our efforts to get rid of this national badge of inferiority so complacently fastened upon us. After visiting the "Department of Art" and the schools, he reported his impressions, and the concluding sentence in his report is—"Lyons is warned, and will fight valiantly to preserve her superiority in the domain of taste and art." If this be not adroit flattery to lull us into a false confidence, and tame our ardour with premature triumph, such an admission is a most satisfactory evidence that we have not entered into a wrong path, and this national care for the interests of Art was truly the only thing wanting to place England, in this respect, on a level with other nations.—*The Press.*

NEW MUNICIPAL OFFICES AND POLICE COURTS, BALLARAT.

We find in the *Ballarat Times* a description of these buildings, for which the models and designs submitted in competition by Mr. C. D. Cuthbert (late of Dublin) were selected. The following are a few particulars collected therefrom:—A tetrastyle portico, 30 feet high, centrally placed, and communicating with a great hall, divided by columns into three compartments—of which the central will be 82 feet by 35 feet, and the sides 47 feet by 14 feet—forms the main entrance, and will be surmounted by a tower, 90 feet in height; a library and museum, each 98 feet 6 inches by 30 feet, occupying the western wing, and the police courts, with their various offices, locks-up, &c., the eastern. Granite is the chief material employed throughout, and the elevations are of plain character. It is said that the ventilating arrangements have occupied much of the architect's consideration. The foundation stone was laid on the 16th of August. Messrs. Evans and Barker are contractors for the first portion—viz., eastern wing and part of centre. Total expenditure when completed to be about £16,000.

VEGETABLE FUEL.

We have received the preliminary prospectus of a company projected "to carry into effect, under a new patent, the manufacture of fuel for 'smelting,' as well as for ordinary purposes, and for the more effective and extensive working of the peat bogs of Ireland." We are at all times pleased to view any effort made for the development of our resources, and in this instance have no reason to question the feasibility of the project, if the financial details have been carefully digested. A successful issue, however, would mainly depend on the extent of the *demand* for the article in question, and whatever may be its merits, we see *one* difficulty looming in the distance for the new company to surmount—namely, want of appreciation. For such of our readers as may desire to be acquainted with particulars, we give the following extracts from the prospectus:—

"When fuel free from sulphur is used in the smelting of ores, the metals produced, vary in value from 25 even to 300 per cent., beyond those manufactured by fuel containing sulphur."

"The effect of sulphur is to lessen malleability, because the particles of the metal become crystallized."

"Almost all metals *now* produced in Great Britain are manufactured from *coal, which in every instance contains sulphur* more or less, and formerly the *iron of Ireland* bore the first mark in the markets of the world, its ores being smelted by *wood* and *wood charcoal*, whereas the iron of Great Britain *now* ranks far *below* the foreign—viz., of Sweden, Russia, &c.—where the superiority arises entirely from its being manufactured with *vegetable fuel.*"

It appears that the new graving dock recently built by the Ballast Board at a cost of £100,000 is not sufficiently large "to dock" the new Holyhead and Kingstown line of steamers. We apprehend it never was intended for such a purpose, being only designed to accommodate those of ordinary, not *extra*ordinary dimensions.

Messrs. Laird's (the builders of the *Ulster*, *Munster*, and *Connaught*) graving dock at Birkenhead is capacious enough to admit the largest vessels yet built, except the *Great Eastern*, the entrance being 87 ft. wide, and the dock 450 ft. long, with a depth of water on spring tides of 22 ft. on the block, whilst the *Leinster* is only 350 ft. long and 65 ft. wide over all. There is also a gridiron outside these works 600 ft. long, which, with some modification, and at a moderate cost, could be adapted to accommodate the *Great Eastern*.

FORTNIGHTLY ISSUE!!!

Subscribers and Advertisers are respectfully informed, that on and after the 1*st of January,* 1861, The Dublin Builder *will be published on the* first *and* fifteenth *of each Month, or, in case either should fall on Sunday, on the day preceding.*

It is, therefore, requested that all who have not as *yet signified their intention of supporting the Proprietor in this undertaking, will have the goodness to do so without delay. Advertisers will favour with their orders referring to a* Fortnightly, *not a* Monthly *issue as heretofore. All Accounts will be furnished terminating with the December Number, previous to commencement of the New Series, and attention is requested.*

A graduated scale for Subscribers will be adopted, particulars of which will appear in next Number.

Illustrations.—*The Editor will consider all subjects submitted for illustration.*

BRAY.

Bray presents just now a busy scene—the hammer and trowel are heard in all directions, and houses of every imaginable class, shape, and capacity are springing up. The poor little village of some few years since, where the arrival of an occasional mail car or excursionists' carriage would cause quite a sensation, has rapidly grown into a populous town, a fashionable watering place—the Brighton of Dublin, at least in embryo. Building ground, formerly set by *the acre*, is *now* difficult to procure even at fabulous prices by *the foot;* during "the season" shopkeepers *now* reap a rich harvest, not as heretofore dragging on a bare existence; streams of visitors *now* emerge from every train solicitous to ensure even a corner in a hotel, where formerly the appearance of a solitary tourist suggested a brisk competition amongst the employeés of rival establishments as to which should become the favoured receptacle of "the stranger." The esplanade is an immense improvement—the introduction of gas a greater. Thanks to steam! thanks to the enterprising spirit of the company who command the iron road approach to the metropolis! and, though last not least, thanks to William Dargan—a name always prominent in the cause of progress—for all this! Glancing at the vicinity, viz., Foxrock, Stillorgan, Ballybrack, Killiney, Dalkey, &c., there is a stir apparent likewise—we shall detail hereafter—which serves to convince that we are not *quite* in that state of somnambulism which some people would persuade the world is a characteristic of "the Irish."

COMPENSATION FOR RAILWAY ACCIDENTS.

With the view of preventing litigation after accidents on railways, a suggestion is thrown out by *Herapath* to this effect—to "establish in case of death a uniform scale according to the class of passengers, viz., *first* class, £1,000; *second* class, £500; *third* class, £250." If that were adopted, we would ask the scale proposed for *compound* and *simple* fractures—how much for the loss of leg or arm respectively, contusions, disfigurements, sprains, bruises, &c.? We confess we do not see the practicability of this adjustment, as it not unfrequently happens that the frieze-coated or smock-frock occupant of a *third* class carriage, with a family, may be in reality a much more important and respectable member of society than many who, to be fashionable and luxuriate in a *first* class carriage, trespass too much on the credulity of their tradesmen, presenting an imposing front with hollowness within. In such a case—and many others which could be adduced—the principle of compensation ought to be precisely reversed, and the larger amount given to the representatives of those whose *moral* worth and social weight would cause their death or injury to be more keenly and extensively felt. That some system ought and might be adopted to diminish the probabilities of litigation from such causes, we quite agree with *Herapath*, but to our minds it can only be effected by several railway companies appointing a paid commissioner or two to enquire into the *circumstances* of each sufferer, and award compensation on the *quantum meruit* scale. Yet difficulties here intervene likewise, for the balance of probabilities would generally be in favour of the companies of whom such commissioner would be *de facto* the employeé, and his sense of impartiality would be severely tested: again, *an award*, unless made a rule of court, or proving (as when would it?) mutually satisfactory, would be mere moonshine, and eventuate in litigation. Moreover we think it not likely that the Government would sanction the legality of arbitration where so much revenue is derived from litigation. However, if practicable even in a degree, "of the *two* evils we would choose *the least.*"

LAON CATHEDRAL.

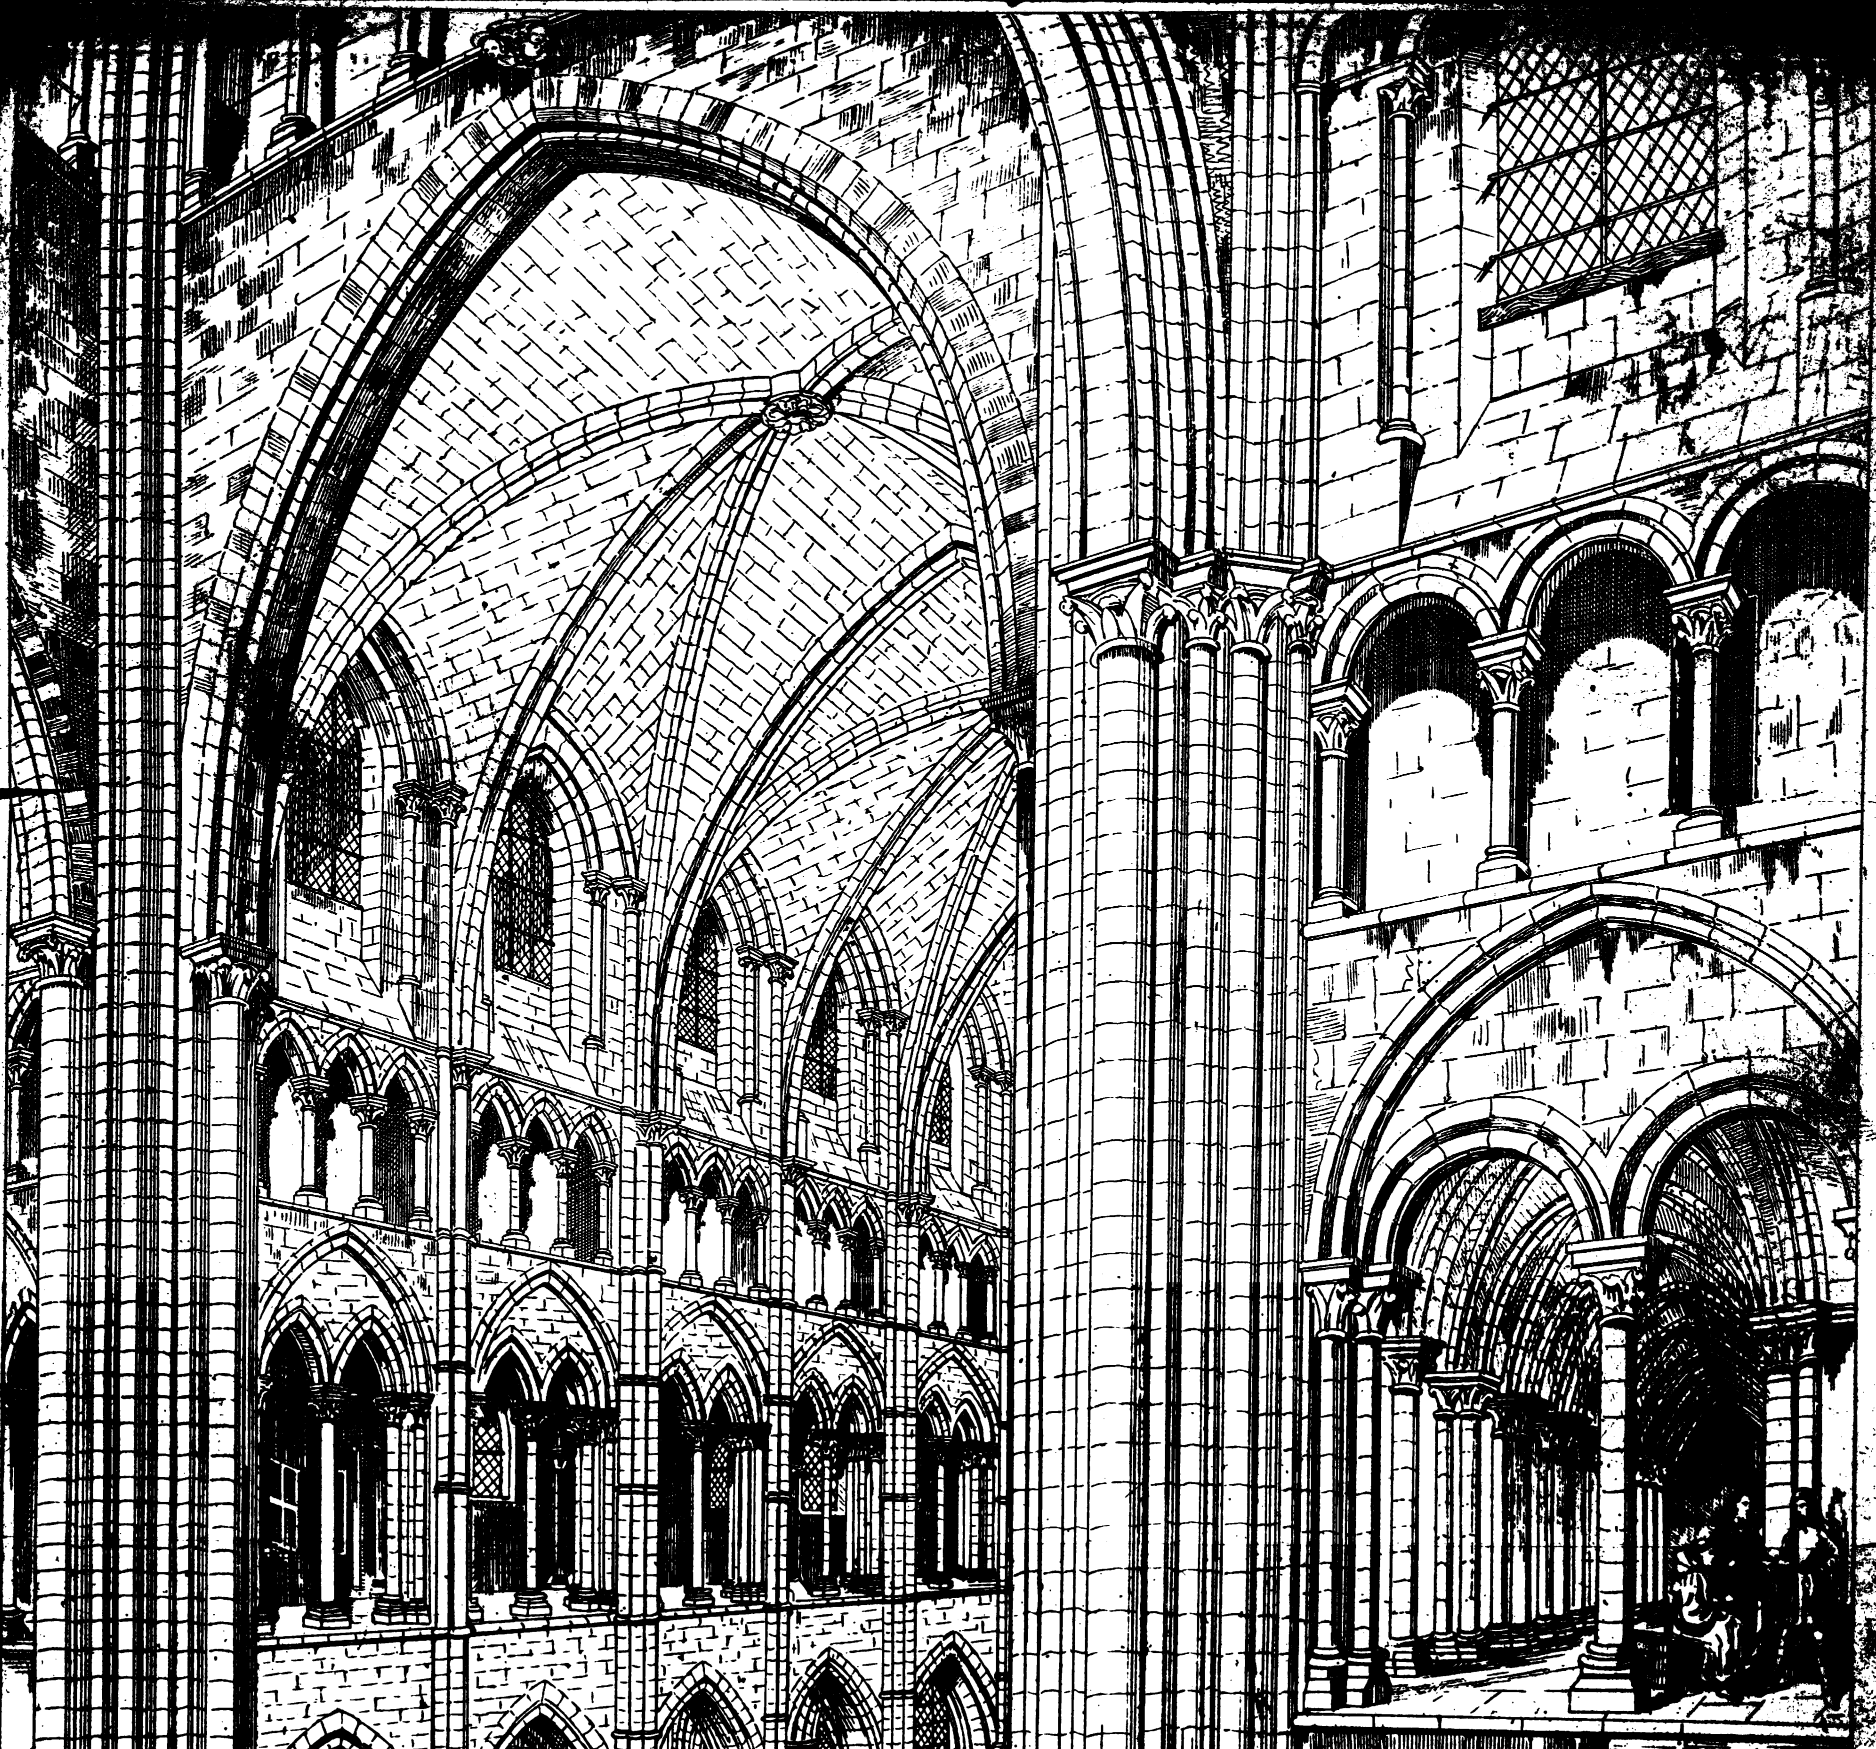
We present herewith a double page lithographic illustration of the interior of this fine continental example, after a drawing which appears in "Architectural Sketches in France and Italy," reviewed in last number, and published by the eminent firm of Messrs. Day and Son, London. The work in question embraces a variety of very beautiful subjects, and we would commend it to our readers.

THE NEW POSTAL SERVICE.

We confess we are not amongst those who bestow unqualified praise upon the Post Office arrangements in some respects, for accelerating the delivery of the mails between England and Ireland, since the new boats were placed on the Kingstown and Holyhead route on the 1st ult.; nevertheless we feel assured that they herald the approach of a system which, when details are well digested in St. Martin's-le-Grand, will prove of immensely increased advantage to the public generally. The chief features in the new arrangement are that instead of *two* deliveries—viz., the morning and mid-day—being requisite for the letters, &c., posted in London or Dublin up to 1 o'clock and 6 o'clock respectively the day preceding, a morning special delivery, due about an hour after the ordinary one, answers the double purpose and discharges both; then another special or night delivery, containing the morning papers and *late* letters, may be regarded as a *supplemental* one. The former answers admirably for all commercial purposes, either metropolitan or provincial, as the mail arrives (at least in Dublin) at a period admitting of the dispatch to the provinces by the morning mail, and the delivery on same day in Belfast, Cork, Galway, and elsewhere being effected. But except in the mere matter of the morning journals of each metropolis being delivered in the other a couple of hours before the ordinary time, we cannot see the advantages derivable by the mass of the commercial community from the *night special* delivery. The majority of our merchants and respectable traders live in the suburbs, if not altogether, at least for a third of the year, and leave their counting houses at 4 or 5 o'clock. Or even assuming that they do reside in town, they hardly like to be disturbed from their *otium cum dignitate* repose after business hours by the postman's knock from 9 to 10 p.m., or are then in the vein to answer letters for the purpose of *saving a post.* There are many instances no doubt in which "necessity has no law," and it *must* be done; but as a general rule, not so. Where, then, is the advantage to the city merchant of this night or *supplemental* delivery? If absent from his place of business, and no messenger employed to convey the letters on delivery, they remain in his box till the following morning, and those posted 15 hours before are found by him simultaneously with those posted on the evening of the day but *one* preceding. To passengers the facility afforded for reaching two points so far distant in such a short space of time, and at certain seasons in the broad daylight, is, of course, most invaluable.

AIR *VERSUS* STEAM!

In most inventions of the present day, wherein motive power forms an element, it is attained by a simplicity of action truly wonderful, when compared with the works of our fathers. The circle of progress hitherto limited is, however, rapidly expanding its diameter, and we must be reconciled if in *their* turn also *our* favourite theories should yield to the modern innovator. Foremost amongst those on which the inventive faculties of man are bent is the application of "air" to mechanical purposes, and we are so strongly predisposed in favour of its pretensions before "*steam*" in point of economy and freedom from complication, that even in *our* time we anticipate the probability of seeing the latter completely superseded thereby, and becoming a mere *thing of the past.* We had an opportunity recently of inspecting, in full operation, at the extensive premises of the patentee and manufacturer in London (a model of which may be seen at the agent's, Mr. Mooney, 26, Summer-hill, in this city), an invention of a very ingenious and meritorious character, in which air is made available to effect a variety of purposes. We allude to Peill's wind engine for driving machinery of various descriptions. For pumping it is especially invaluable, and may also be applied for the uses of the farmer in grinding, cutting chaff, &c.; and for the builder in sawing, planing, &c. Amongst its economical advantages may be enumerated the facts that it costs nothing for fuel, and that the occasional attendance of a lad will be sufficient to regulate, alter, or stop its course. Moreover, we are pleased to learn that numerous orders have been received from various parts of Ireland for its construction, and that the manufacturer is at present busily engaged in their execution. The nature of the invention is however such as to suggest a doubt of its applicability under all circumstances of the atmosphere; but though it must be conceded that when the wind does not *blow* the engine will not *act*, nevertheless in this climate it will be admitted that a *dead calm* so seldom takes place that undue stress need not be laid on the difficulty. An examination of the model will satisfy as to further particulars.



W. M. MORISON, LITH, DUBLIN.

INTERIOR VIEW.

THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS

THE SESSION OF 1860-61.

On the 5th instant the Institute of British Architects is to hold the opening meeeting, and according to present announcement, Mr. Sidney Smirke, R.A., will read a paper entitled "Recollections of Sicily." At the Royal Academy the same gentleman is to deliver lectures on architecture on the evenings of January 24th, 31st, and February 7th. The Architectural Association held its first conversazione for the Session on the 26th ult., and as the syllabus betokens much earnestness of purpose we publish it *in extenso*:—

"Oct. 26. Conversazione and Opening Meeting.
Nov. 2. Class of Design—Verandah.
9. Consideration of the Subject of Architectural Examinations and Report thereon.
10. Class of Design—Entrance Lodge and Gates to a Mansion.
23. Consideration of the Subject of Architectural Examinations and Report thereon.
30. Class of Design—Capital to a Column Quarter Full Size.
Dec. 7. A Paper will be read by Mr. Bloomfield, M.A., on the "Arrangement of Churches."
14. Class of Design—Grand Staircase to a Mansion.
21. A Paper will be read by Mr. R. W. Billings.
28. Class of Design—Timber Truss for roof fifty feet span. N.B.—Scantlings to be stated.
Jan. 4. A Paper will be read by Mr. Arthur Allom, on "The Battle of the Styles."
11. Class of Design—Town Gateway.
18. A Paper will be read by Mr. J. A. Bunker, on "Foundations."
25. Class of Design—A Villa.
Feb. 1. A Paper will be read by Mr. R. Druce, on "An Architect's Audience."
8. Class of Design—A Conservatory.
15. A Paper will be read by Mr. G. B. New, on "Brickwork."
22. Class of Design—A Stable and Coachhouse.
March 1. A Paper will be read by Mr. Thomas Allom, on "Light and Shade."
8. Class of Design—Tympanum with Sculpture.
15. A Paper will be read by Mr. J. H. Christian, on "Masonry."
22. Class of Design—National Schools.
29. Good Friday.
April 5 Class of Design—Ornamental Hinges.
12. A Paper will be read by Mr. T. Blashill.
19. Class of Design—A Seven-light Window.
26. Conversazione.
May 3. Class of Design—Principal for Iron Roof over a Railway Station 8 feet span.
10. Special Business Meeting.
17. Class of Design—Encaustic Tiles.
24. A Paper will be read by Mr. R. O. Harris, on "Carpentry."
31. Class of Design—Interior of a Library.
June 7. Nomination of Officers.
14. Class of Design—A Porch.
21. Election of Officers.

"Prizes will be given for the best Essay on "Street Architecture and its Treatment," and for the best Series of Sketches made by the Class of Design during the Session.

"Half hours in Botany on the evenings of Ordinary Meetings, to be opened by Mr. Thomas Blashill."

The Liverpool Architectural and Archæological Society has had *two* meetings, and at the second, viz., the 17th ult., special consideration was given to the "Diploma Question" as proposed by the Institute of British Architects, but decision postponed till the next ordinary meeting.

The various archæological societies—including the London and Middlesex, which is the most important—have nearly all assembled. At home the Royal Dublin Society, Museum of Irish Industry, Institute of Civil Engineers, Kilkenny Archæological, Dublin Chemical, Ossianic, and others, have also commenced their labours, verifying, however, the Shaksperian proverb, that "the labour we delight in physics pain." Of those abroad we experience peculiar pleasure in recording the operations of the American Institute of Architects, whose members are so near akin in sympathies to those of the United Kingdom, and who since its establishment have displayed so much of that "go-a-head" temperament which is said to be a characteristic element in the Transatlantic constitution. Judging from appearances, the session promises to be a very successful and busy one.

PROPOSED NEW CHURCHES FOR MONKSTOWN PARISH, CO. DUBLIN.

By the Church Temporalities Amendment Act, passed last session, power was granted to divide this parish (hitherto extending to Stillorgan, and beyond the Golden Ball, also as far as to part of Killiney), and to create thereby two additional distinct parochial districts —namely, the parish of Kill and the parish of Tully; a perpetual curacy, with a stipend of £100 a-year, payable by the Ecclesiastical Commissioners for Ireland, to be attached to each. We understand these partitions have already been made, and the school-house near Ballycorus Mills has been licensed as a place of worship in the parish of Tully until a church be built. In the parish of Kill it is proposed to erect a church forthwith, but the site is not yet fixed upon. This, however, is merely a matter of selection, as Messrs. Bentley have offered to present an acre of their land at Foxrock for the purpose, rent free for ever; Mr. Perry has likewise offered a site on his land, near the Kill of the Grange, nearly in the *centre* of the parish. The former, however, bids fairly to become very shortly much more in the centre of the parishioners, which is after all the point of importance, and having the decided advantage of superior elevation, we presume will be adopted; besides, being convenient to the Dublin and Wicklow Railway, many persons from Dublin would help to increase the congregation in fine weather.

IMPROVEMENT OF THE STREETS.

A correspondent addresses the following observations to *Saunders' News-Letter*:—

"Permit me, through your much read paper, to express a hope that the new carriage-way now being made behind the Four Courts is not intended to be permanent. I do not know whether it is in the hands of the Corporation, the Board of Works, or the Benchers of the King's Inns, but surely whatever body has the control of it ought not to offer such an insult to public taste as to run a line of street in a very oblique direction to a handsome pile of building. It is obvious that the new range of building at the rere of the Courts ought to form one side of a fine oblong square, or the diameter of a semicircular space, with a line of street leading towards the King's Inns, from immediately opposite to the Solicitors' Buildings. This square or semicircular space might be made at once, together with the beginning of the new street, which at any future convenient time might be carried on; but if houses to range with the present new line of roadway should once be commenced, the thing would be hopeless, and a permanent eye-sore created as a constant annoyance to all who are anxious for the embellishment of the city. I may as well take this opportunity of urging the Corporation to interfere if they have the power, and to prevent any more tolerably regular streets from being disfigured as Lower Sackville-street and Westmoreland-street have been, by the fine uniformity of these streets having been marred by all sorts of fantastic and tasteless elevations plastered up. As for Kingstown, it is a hopeless mass of jumblement."

SAUNTERINGS IN THE SUBURBS.

Devoid of interest to the citizen or the antiquarian researcher as may *appear* the locality of Drumcondra (formerly a remote suburb, but now a northern wing of the Irish metropolis), it is nevertheless not wholly so; for within the circle comprehended by that title may yet be conjured up some few subjects not altogether without historic association. Foremost among those—however strange the precedence suggested may appear—is the fragment of a venerable elm, popularly known as the "big tree," from time immemorial identified with a celebrated court of justice (?) held in the immediate proximity. Few years have elapsed since a summons to the "big tree" was regarded with as much concern as an appearance before the Court of Queen's Bench—the one doubtless serving as the inevitable forerunner to the other; but it, together with other manorial and judicial establishments—viz., St. Sepulchre and Mary's-abbey—have yielded to modern innovation, and become mere matters of the past. Previous to the hurricane of 1839, this notable elm preserved its majestic proportions uncurtailed, but on that eventful occasion was cleft in twain and "nought but a wreck left behind." Moreover, the history o lthis tree is associated with the name of the ever-memorable Dean Swift, who is said to have planted it—a statement, however, we are not prepared to vouch. Passing further, we notice a structure popularly known as Kellett's schools, a bequest being granted therefor by Miss Anne Kellett in 1811, and recorded on a tablet in front until effaced by recent external alterations, but now forming the female school of St. Francis Xavier. A few years since it was burned, save the walls, the original of which are still standing. Turning at right angles to the main road we find Jones's-road, so styled after Frederick, *alias* "Buck" Jones, formerly patentee and manager of old Crow-street Theatre, and whose former mansion, known as Clonliffe, is placed somewhat midway, and celebrated for a tragical occurrence between the military, Jones's servants, and some burglars. This house has undergone many changes, and after remaining for a considerable time idle it was taken by Government for a revenue police depot; but owing to the amalgamation of that body with the constabulary, became again unoccupied, and was subsequently purchased by Archbishop Cullen for a preparatory ecclesiastical college, and is now known as Holycross College, Clonliffe. It was at one time in contemplation to continue Russell-street road across Fortick's Grove, by bridging the Tolka at Richmond; and had this been effected some twenty years ago it is probable that the northern suburbs would now supersede the southern. Drumcondra bridge crosses the Tolka—a river of old poetic associations and patriotic memories, though a late writer in an Irish periodical could "see nothing in it" but its water-carriers. Belvedere House, close by, once the residence of Sir Coghill Coghill, Bart., was also the seat of Lord Chancellor Lifford, and is a brick building of somewhat antiquated fashion. How the memories of forty years crowd upon the mind in contemplating Clonturk House, formerly the residence of the notable Dhuval! Here another Portobello Gardens were placed, various kinds of amusements provided, and, it is said, artificial spas, to impose on the credulity of hypocoudriacs and dyspeptics, manufactured by the aid of old iron and sulphur. A short distance from Clonturk gateway is the lane leading to Drumcondra burial ground, where Grose, the antiquary, Gandon, the architect, and Furlong, the poet, "sleep their sleep of peace." Some of the monuments are in a good state of preservation, and inscriptions nearly 200 years old may be deciphered. Opposite stood, about thirty years ago, a famous tavern and place of resort during Dhuval's time, and said to have been patronised by the corporation of Dublin for their public dinners, when, in what are designated "the good old times," the gastronomic art occupied no small share of corporate consideration. Evidencing the vicissitudes of fortune, we may note that the proprietor of this establishment, whose thousands were at one time almost countless, ultimately sat by his basket at the foot of the bridge, a mere mendicant.

Facing the main road is the once celebrated Cat and Cage Tavern, and a few paces on is the Post-office (where the brilliant Lady Morgan spent a portion of her girlhood), in 1820 a widows' alms house, and in 1790 the station for the royal troops to intercept the rebels in their course to the city from Swords and Santry. The Missionary College of All Hallows (illustrated in number 14 of the DUBLIN BUILDER) is also in the immediate neighbourhood, the original building of which comprises a square block erected by the Earl of Charleville in the last century, and the modern additions were built under the superintendence of Mr. M'Carthy, architect. This was also the habitation of Sir John Claudius Beresford of '98 memory, and subsequently of Sir Guy Campbell. It is conjectured that on the site of this building Saint Malaga had a church and religious establishment, called in the Annals, Laorn Beachaire, in Fingal near Dublin. Opposite the college is Drumcondra Castle, on the Goosegreen-road, a castellated structure of the era of the revolution, long in possession of Mr. Richard Williams, of Dame street, and for some time the residence of Sir Duncan M'Gregor. Adjoining the castle to the south is Grace Park, once occupied by the memorable Major Swan, the friend and associate of Major Sirr. We find ourselves on the threshold of adjoining districts which will more properly be treated in a separate article, so for the present we close.

HINTS ON VENTILATION.

No subject connected with the duties of an architect demands *more* study and careful attention, or receives *less*, than that of "*Ventilation*." The primary considerations of our modern building practitioners are, effective elevation and comprehensive internal arrangements; but the sanitary welfare of the inmates is regarded as purely secondary, if even in that degree. Under the above title, a series of papers, which originally appeared in the *Dublin Medical Press*, is now reproduced in pamphlet form by the author, Mr. John Louch, one of the oldest and most respected members of the profession in Dublin, and second to none in his devotion to the philanthropic pursuit of sanitary science, or in competency to treat the subject in question. Mr. Louch commences at the foundations of a building, and demonstrates how a want of precaution in providing against the natural exhalations of the earth, malaria, &c., ensures the existence of "damp in dwellings," and is productive of most detrimental results.

The old proverb, "that a stitch in time saves nine," is forcibly illustrated, and the author, with an eminently practical mind, first points out the causes and results, and then suggests the remedy. Let us hear what he proposes to ensure a dry house:—

"My practice for many years has been to sink the ground composing the *basement* floor of a building to at least two feet under its level, and sinking the ground for three feet around it, removing all the *earth* taken out to a distance, filling in the entire space with sharp broken stones, or clean gravel free from any loamy matter, and over this spread two or three inches of clean mortar. The footing courses of masonry of all the walls of buildings *should be built dry, free from mortar;* these precautions, with proper drainage, will effectually prevent damp in ground floors, and will make them, in a measure, as wholesome as the upper floors of dwellings. I have known floors of places of worship, although they were six feet from the earth, become rotten from the effects of the exhalations from the earth, and had to be replaced at a great cost, *the ground of which had been well sewered.* The upper parts of buildings may be made dry by proper eave and other gutters from the roofs, and the external face of the walls cemented."

Again, referring to the ventilation of sewers, he says:—

"In speaking of sewers, many schemes have been suggested as necessary to remove from them the various gases generated by the decomposition of putrid matter lodged and passing through them, and much controversy has ensued in consequence. Now, to overcome such a task as to try and ventilate *sewers*, would be as difficult as to remove the poison generated in its great abundance and intensity in marshy and swampy lands. All that can be expected to be done, is to prevent its escape into our dwellings, by proper sink-traps, &c. Be assured if you keep the poison confined within its limits it will be *innoxious*, and why impregnate the air of cities or towns with it to ventilate sewers."

The all-important subject of "Hospital" ventilation occupies much consideration in this pamphlet, and the following example is cited to illustrate the necessity of ensuring a pure atmosphere in all establishments where sick persons may be:—

"About the year 1821 or 1822, the St. Patrick's, or Swift's Hospital, in Dublin, had its corridors or wards heated on the principle of the hypocaust, and the large fireplaces done *away with.* Looking to the construction of this hospital, it will be seen it consists of a centre, with two buildings running *parallel* from its rere, containing wards or corridors—each about 320 feet long by 14 feet wide, and of sufficient height; off these corridors are the various cells and day rooms—the former are 12 feet by 8 feet 6 inches, and opposite to the cell windows are similar windows in corridors. The buildings are in height two floors above the ground floor. It was always considered *salubrious*, and in which the patients lived to an old age. Soon after the introduction of the hypocaust as a mode of ventilation and heating, the mortality amongst the patients appeared to be very great, and caused considerable anxiety to the *governors* and physicians in charge. It became necessary to remove it; as soon as this was done, the health of the patients was restored, and since that *period* the large fireplaces (three to each corridor) have been used, with iron guards to them. (I see, on looking to the plans of most of the new asylums for insane, that the open fireplace is used as the mode of heating the corridors.) Since the period first mentioned, the windows, both in corridors and cells, have been considerably enlarged, the doors constructed to do away with, as much as possible, the prison appearance, and the patients receive as much liberty as their circumstances admit of."

In speaking of barrack-rooms the author denounces as a failure the system adopted under the directions of the commission, and says:—

"I mentioned my opinion at the time, that the shafts so formed for the exit of vitiated air would 'act as down-draught shafts, and will be continually stopped.' This opinion was formed about five months ago. I can now state with confidence that for a safe mode of ventilation it has proved a complete failure. The men suffer exceedingly at night from the quantity of cold air that blows down on them, and they are obliged to stop them up."

A glance is then given at the history connected with the ventilation of the Houses of Parliament, and the pamphlet concludes with the following:—

"I have now brought under notice every matter I consider necessary on ventilation, and I have confined myself to such matters as may be carried out in all buildings as suited to our requirements, and hope that sanitary measures may become an essential part of the profession of an architect. I do not wish in the least degree to *dictate*, but an experience of many years' practice shows me that a continued study of the branches of sanitary architecture is one of the best qualifications in a member of my profession."

Altogether this is an instructive and readable little book, combining scientific theory with practical experience, and if not as formidable or comprehensive as previous works, it has the merit of presenting, in a very small compass, much to be learned by all, not even excepting established practitioners.

Among the list of subscribers for St. Andrew's new church we find Alderman Atkinson and the Rev. Mr. Bourne, vicar, for £500 each; the Bank of Ireland, £200; the Duke of Leinster, Andrews and Co., Pim, Brothers, and the Royal Bank for £100 each; besides numerous others for various lesser sums.

Notes of New Works.

A new Roman Catholic church is in progress of erection at corner of Leicester-avenue, Rathgar. The plan is oblong, 132 feet by 45 in clear, with apsidal chancel and side aisles. A granite portico will form the front, and a campanile immediately over same. The general walling will be of black stone, with granite dressings, string courses, &c. Mr. Patrick Byrne, architect; Mr. Jas. Freeman, builder. Expenditure about £4,000.

The front of the Prince of Wales' Hotel in Sackville-street is being newly decorated in cement, under the direction (we believe) of Mr. Nagle, C.E.

The front of Mr. Sexton's (clothier) new shop in Dawson-street is entirely composed of Cork red and Connemara green marbles, and was erected by Mr. A. Colles, of Millmount, Kilkenny; Mr. Caldbeck, architect. We hope to see numerous others erected of same material.

Messrs. Cherry and Shields are decorating, but with very questionable taste, the front of their establishment in Upper Sackville-street.

Austin's new warehouse in Westmoreland-street, now partially completed, will present one of the most *attractive* fronts in the city, a consideration too often attained at the sacrifice of architectural merit.

A commencement will soon be made with the works of the new Roman Catholic church to be built at Donnybrook.

Two dwelling-houses are being built near the Dalkey railway station by Mr. Cunningham, after plans by Mr. Wilkinson, architect.

A new Protestant chapel is being built at Richmond Lunatic Asylum; same architect.

Malahide bridge is partially completed; the piers are of massive stonework, and sustain a superstructure of iron. Owing to the very strong current which flows at this point, much difficulty was experienced in carrying on the works, but all seems to have been ably accomplished by the engineer, Mr. Harty. We regret, however, to find that, owing to some want of caution, one of the workmen was recently drowned there.

A new station is to be built at Foxrock by the Dublin, Wicklow, and Wexford Railway Company, according to plans by Mr. Wilkinson, architect. The directors seem to have met the desires of property holders in this growing neighbourhood with a commendable promptness.

The new Roman Catholic church of St. Baithius, at St. Johnston, Derry, is progressing to completion.

Additions are being made to Killiney Church. Mr. Symes, architect; Mr. Millard, builder.

Six houses of a very superior class, and with handsome oriels carried up two storeys in height, and filled with plate glass, are being erected by Mr. Crosthwaite at Kingstown.

The Board of Public Works are raising a portion of the wall on the eastern pier at Kingstown, so as to protect the shipping in the harbour from the force of easterly gales.

An apsidal chancel has been recently added to Ballyshannon Roman Catholic church, after plans by Mr. M'Carthy, architect. It is handsomely decorated with panels, figures, and scroll-work. The side altars are also enriched with enamel, and the splays of the windows coloured. Stained glass, from the establishment of Messrs. Barff and Co., has likewise been introduced into the windows over the side altars.

It is proposed to erect a vicarage at Killeroran, in the diocese of Elphin, county Galway, and the owner of the soil, Mr. D. H. Kelly, has given nearly five acres of land in perpetuity, as also £100 subscription, for that purpose.

A line of tramways is to be laid down in Cork, on the patentee's own responsibility.

A new church is to be built at Kilcock, Co. Kildare; Mr. M'Carthy, architect. It will be about 120 feet long by 60 feet wide.

The new Ulster Bank at Belfast has been opened for the transaction of business. Full particulars of the design have already appeared in this journal.

The proprietors of the Royal Victoria Hotel, Killarney, are about erecting on a magnificent scale and in a commanding position another hotel structure. The present building will also be partially raised, and architecturally decorated.

A new church, to be dedicated to St. Ignatius, as also extensive schools and clergyman's house, are to be built in the town of Galway, according to plans by Mr. J. J. M'Carthy, architect.

William Smith O'Brien has taken a site for a marine residence at Liscrona, on the estate of Major Armstrong M'Donnell.

A new Presbyterian church is to be erected in the town of Wicklow, according to plans by Messrs. Hay, architects, Liverpool, who designed Sandymount Church.

Repairs and alterations are being proceeded with at the church of St. Saviour, Limerick. The interior is being formed into nave and aisles; an apsidal chancel, and tower with spire are also being added. Mr. M'Carthy, architect; Mr. John Ryan, builder.

Major M'Donnell, New Hall, has given down his name for £1,000 towards the erection of a hotel in Kilkee, on the style of Gresham's commodious establishment in Kingstown. In the same town two new houses are to be built by Miss M'Manus.

An addition is about to be built to Castlecomer Convent, after plans by Mr. M'Carthy, architect.

The new male and female model schools erected by the Board of Works at Parsonstown have been completed, at a cost of nearly £2,000.

The plan of the new church of St. Mary's, Guidore, recently consecrated, is after the form of a Latin cross, consisting of nave, chancel, and transepts. The extreme length of the nave and chancel is 112 feet; transepts, 40 feet each. The walling is of local grey granite rubble work, except the chancel, which is of cut stone, and is surmounted by a cross, beautifully carved. The walls are 30 feet high, pierced by 15 windows of considerable height, of 2 lights each. The eastern, or chancel window, is 25 by 10½ feet, intended hereafter to be filled in with tracery and stained glass.

The new church now in progress of completion at Taghadoe, Co. Kildare, is a parallelogram in plan, with nave 58 feet 6 inches by 21 feet, chancel 18 feet by 15 feet; tower on spire (75 feet high) at north-west angle, and sacristy at south side of chancel. Open timber roof, single lancet lights in flanks, triple ditto in east end, and two-light ditto with circle in the head at west end. The upper part of spire is of timber, and slated. The interior is provided with open benches, stained and varnished, Caen stone altar, by Purdy and Co., of Dublin. Mr. M'Carthy, architect; Mr. Beardwood, builder.

A new house and offices are about being commenced at Avoca Avenue, Blackrock, for George Stormont, Esq. Mr. Louch, architect; Mr. Strahan, of Rathfarnham, the builder. Expenditure about £1,300.

RAILWAY MEMORANDA.

The directors of the Midland Great Western Railway (as may be seen by our advertising columns) are about at once proceeding with the construction of the Liffey branch line.

The extension of the Dublin, Wicklow, and Wexford Railway is being worked in sections at various distances between the Murrough of Wicklow and the populous town of Rathdrum. It will branch off from the present main line some distance beyond Killoughter, and little short of the town of Wicklow, bending round by the village of Rathnew, and then taking a direct line for Rathdrum. Nearly a thousand men are employed on the works. Mr. Thomas Edwards is the contractor, Mr. W. R. Lefanu, the engineer. It is quite hoped that the extension may be open as far as Rathdrum by next summer.

Mr. Hill, C.E., estimates the construction of the Clara and Portumna Railway at £5,000 per mile, exclusive of a bridge over the Shannon to cost about £10,000. The surveys are being proceeded with.

A large staff of engineers is at present engaged in preparing the surveys and plans for the projected railway between Newry and Downpatrick.

Arrangements are in progress for surveying the long projected line of railway between Roscrea, Nenagh, and Birdhill.

Messrs. Bright and Smith are the contractors for the Castlerea and Claremorris extension railway.

The Marquis of Clanricarde and others are favourable to a proposed railway from Parsonstown through the county of Tipperary to the Shannon, opposite the town of Portumna.

From 1,200 to 1,500 navvies are employed on the Cork and Youghal Railway.

The viaduct which connects the Ballymena and Portrush Railway with the Derry and Coleraine line has been finished, thereby insuring through journey by rail between Belfast and Derry.

Review.

Facts and Fallacies of the Turkish Bath System. By Dr. Haughton. London: Simpkin & Marshall. Edinburgh: John Menzies. Dublin: W. Robertson.

FOR some time past one of the most engrossing topics for public consideration has been whether or not the introduction of the Oriental bath system into these countries would be attended with salutary effects, and while some were talking and arguing vociferously against it, its votaries were practically assuming the initiative, and we find them now dispersed throughout the kingdom in various classes of buildings, from the least pretentious to the most imposing. Perhaps, therefore, a conclusive proof in their favour is, their extensive adoption and appreciation by the public, and for the opportunity thus afforded those who have derived benefit therefrom are mainly indebted to the energy of "our author," who has devoted himself to the cause with a commendable zeal. The treatise before us is of a more comprehensive character than that previously noticed in this journal, opening with a reference to the prejudices displayed by "certain leading members of the medical profession towards the employment of dry air at a high temperature for bathing purposes," the Doctor advocating that "up to the present date baths *without moisture* have been almost exclusively used as remedies." Unwilling to assume an authority on a matter of which we have had no practical experience, we must leave the question of the "dry air" and "the moisture" respectively for decision by the faculty; but as the usual principle of construction is one in which our readers are more or less interested, we quote the following plan of Count Rumford's from the pamphlet:—

"Let a small building be erected, fourteen feet five inches long, and nine feet wide measured within, and seven feet high, and let it be divided into equal rooms of nine feet long, and seven feet wide each, by a partition wall of brick, four and a-half inches wide, or equal in thickness to the width of a brick Let the outside walls of this little edifice be *double*, the two walls being each the width of a brick in thickness, and the void place between them being likewise of the same thickness, viz., about 4½ inches. In order to strengthen these *double* walls, they may be braced and supported one against the other, by uniting them in different parts by single bricks laid across, with their two ends fixed in the two walls. Instead of a floor of boards, these little rooms should be paved with 12 inch tiles or flat stones laid in such a manner on thin parallel walls (4½ inches in thickness) *as to form horizontal flues under every part of the pavement.* At the end of the rooms opposite to the door, a *bathing-tub* should be placed, and in the other a caned sofa. The boiler, which need not be made to contain more than six or eight gallons, should be well set in brickwork, and well covered over with bricks, to prevent the loss of heat which would result from any part of the boiler being exposed naked to the cold air of the atmosphere. This boiler should be fitted up by means of a ball cock, so as to feed itself regularly with water from the neighbouring reservoir. The boiler should be furnished with a safety-valve, opening into the open air, and with a tube for conveying steam into the bathing-tub. This tube, which may be a common leaden pipe, about half an inch in diameter, should be wound round with the list of coarse cloth, or with any warm covering of that sort to confine the heat. This steam tube should rise up perpendicularly from the boiler to the height of eight or ten inches above the level of the ceiling of the bath-room, and should then be bent towards the building, and made to enter the roof of it, and then to descend perpendicularly through the ceiling of the bath-room and enter the bathing-tub. Its open end should reach to within an inch of the bottom of the tub, and a little above the level of the top of the tub there should be a steam-cock, by means of which the passage of the steam through the steam-tube, and into the water in the bathing-tub, may be regulated, or prevented entirely, as occasion may require. There may be a short branch, six or eight inches long, inserted into the steam-tube just described, which branch will serve for admitting steam into the room *when it is designed to be used as a steam or vapour bath.* This short branch must, of course, be furnished with its own separate steam-cock. The smoke from the (closed) fire-place of the boiler must be made to circulate under the pavement of the two rooms of the bath, in the flues constructed for that purpose, before it is suffered to pass off into the chimney. The chimney should stand on the outside of the building, and be made to lean against, and be supported by the wall of the building. There should be a damper in this chimney. . . . If it be required to heat the two rooms in a very short time—the one with vapour and the other with dry air, equally warmed and perfectly free from all disagreeable smells, this may be done by the following simple contrivance:—Let a cylinder of very thin copper, about eight inches in diameter, and five feet in length, be placed horizontally under the sofa in the dressing-room, and let the steam-pipe from the boiler be laid into it, with another pipe for carrying off the water resulting from the condension of the steam in it. By admitting steam into this tube the air in the room will soon be warmed, without any watery vapour being mixed with it; and by admitting steam into the bath-room, and allowing it to mix with the air of that room, a vapour-bath will be formed, and in a very few minutes will be ready for use."

The able and comprehensive manner in which Dr. Haughton treats his subject entitles him to much commendation.

As an evidence of the business done by the Great Northern Railway Company of England in "coal," it is stated that the postage of the circulars announcing the transfer of the department to an independent manager cost £125, and the time of twenty-six female clerks for a fortnight to fold and address the envelopes. Total number of circulars issued *per post—thirty thousand only!* How many by delivery, deponent knoweth not.

Mr. Barlow proposes to construct an aerial railway over London, on the suspension girder principle, with spans of 1,000 feet, and maintains that it would not exceed in cost £150,000 per mile.

Miscellaneous.

The opening of the recently erected free public library at Liverpool has been celebrated with much *eclat* and a splendid banquet. Upwards of 4,000 volunteers marched in procession through the town. Lords Brougham and Stanley, Sir R. Peel, the Bishop of Chester, and Mr. William Brown, at whose expense of £40,000 the buildings were erected, were amongst the speakers. A statue of the munificent doner, and from the chisel of Mr. M'Dowell, was unveiled on the occasion. We are proud to say that Mr. Brown is "an Irishman," having being born in Ballymena in 1784, and having amassed a colossal fortune, has given this great proof of his philanthropy in disbursing it.

Some workmen at Nottingham recently turned up out of trenches for foundations of a new building a quantity of warlike, religious, and other implements, which are believed to have belonged to the inhabitants of Britain before the Roman invasion. They were purchased by an antiquarian.

The British Association for the advancement of Science will assemble in Manchester in 1861; Mr. Fairbairn is appointed president. A preliminary meeting has been held, and a guarantee fund list opened.

It is stated that the Board of Public Works is about causing a number of houses to be pulled down at Fortyfoot-road, Kingstown.

New water works are proposed for the town of Tralee.

The death of Mr. Jonathan Forster, the oldest engineer in the north of England, was announced last month. He was engineer at Wylam Colliery when experiments were made which ended in the adoption of the locomotive.

During the recent restoration of St. Peter's Church, in the Isle of Thanet, a curious piece of panel sculpture (in alabaster) of the Crucifixion was discovered.

The competition continues open till the 1st December for the prizes which "The Architectural Museum" (at South Kensington) has offered for good example of modelling, metal work, wood carving, of cartoons for painted glass, and of coloured decorations.

At the last sitting of *the Academy of Sciences*, M. Wothley, of Aix-la-Chapelle, sent in some specimens of a new process for enlarging photographs taken on collodion, either by solar or electric light. M. Wothley states that he arrives at these results by a series of manipulations, constituting almost a new art. By means of a heliostat he directs a broad pencil parallel of rays upon the negative impression. The light, in passing through, forms a wide cone of diverging rays, which casts the enlarged image on a sheet of prepared paper. The impressions thus obtained may be of almost any dimensions; M. Wothley has produced some 8 feet by 5. The exposure to the light lasts about 25 minutes. For washing and fixing the impressions he employs various dexterous manipulations, rendered necessary by the large surface to be operated upon.

One of the great water pipes conveying the water from Loch Katrine to Glasgow burst recently, inundating the village of Maryhill, destroying gardens, avenues, &c., forming rugged channels in the streets, and carrying away kerb-stones, &c., before the progress of the water was even partially stopped.

Mr. Hobbs, the famous opener of locks, having taught the British public that there is really no such thing as a lock proof against being picked by an artist, is now about to return to his native country, there to spend in easy competence the remainder of his days.

A new arrangement of screw propellers tried a short time since on the Serpentine is said to have been very successful,—the model, of only three tons burden, towing two barges laden with 90 tons of stone in shallow water at the rate of three miles an hour, with 20lb. steam pressure on the boilers.

A novel application of the electric light was made recently at Shaffhausen, on the Rhine, in the illumination by five lamps of the celebrated cataract there. The effect is said to have been wonderful, and greatly enhanced when coloured glass was employed.

A steel plated shot-proof steam vessel, 400 feet in length, is now being built at Chatham Dockyard for the Government. She is to have Armstrong guns of the heaviest metal and the longest range.

Mr. Howe, the inventor of the sewing machine, has, after much opposition, succeeded in obtaining a renewal of his patent in America.

An experiment to substitute steel for iron in boilers has failed, it being found that the expansion and contraction of the former is much greater than the latter.

A rifle bullet takes upwards of three seconds to fly 900 yards, and nearly eight seconds to fly 1,800 yards.

Mr. John Greacen, jun., of New York, is said to have invented a means for preventing the emission of smoke from the funnels of locomotives, and has arranged that the tubes of the boiler are combined with reversible funnel connections, conveying the smoke to the rear of the train, and thereby obviating much discomfort to the passengers.

The screw propeller was described and sketched by James Watt in a letter written in 1770.

The proposed great hotel at London-bridge is *not* to be built, as the directors have accepted an offer of the London and Brighton Company of £30,000 for their lease of the premises, with the choice of another site, to which access will be given, refused in the former instance.

A Good Drawing Pen.—We can speak somewhat confidently after three months' experience of a new drawing pen forwarded to us by the inventor, Mr. Stanley, mathematical instrument maker, of Great Turnstile, Holborn, London. Its chief merit consists in the strength of the under nib, which in most cases is so constructed as to yield to the slightest pressure against the square, and consequently produces a line of unequal thickness, but by the pen in question that defect is completely rendered impossible. Our attention has also been directed to a new form of T squares manufactured at this establishment, and which are considerably wider at the stock than at the extremity, ensuring a much greater steadiness of motion than those ordinarily in vogue.

New Street for Calcutta.—The opening of a new street between Jaun Bazar and Dhurumtollah, the breadth of which is to be thirty-six feet, has been sanctioned; the estimated cost of this is 20,000 rs. Also, it is proposed that the portion of Sudder-street which lies between Madge's-lane and Chowringhee-road, should be widened to 50 feet, and that a good and convenient entrance from Sudder-street to the Small Cause Court should be made; the cost of this improvement is estimated at 44,000 rs.

A Curiosity.—A subscriber in a northern town forwards us the following paragraph, copied *verbatim* from an architect's specification, and says, he never knew the *quality* and *dimensions* of workmen to be provided for in a specification before:—"All materials and *workmen*, that the inspector may consider not in accordance with the terms of the specification, in *quality* or *dimensions*, are to be removed on notice off the company's premises by the contractor, and proper materials supplied by the contractor, and also efficient workmen."

American-fashioned Steamers for Lough Erne.—We learn that the Erne Company propose placing on this lake (the "Windermere" of Ireland) steamers on the same model as those on the River St. Lawrence, combining great speed, light draught of water, good carrying qualities, with luxurious saloons, and cheap fares. On the St. Lawrence they are under 200 feet long, the locks of the canals only admitting that length; but on the Great Lakes and Hudson River they are from 350 to 500 feet, their beam usually being from one-ninth to one-eleventh of their length. On the Hudson are the fastest and finest river steamers of the world, attaining a speed of 25 to 28 miles per hour; some of their saloons are luxuriously furnished, being from 300 to 400 feet long. With the same fuel and equal cost, they can carry four times the number of passengers.

Novel Aqueduct Bridge.—The city of Washington, in the United States, has made a noble effort to supply the capital with pure water. An aqueduct bridge is one of the most important features in the engineering works. It was constructed to satisfy the double necessity of furnishing both the capital and the neighbouring city of Georgetown with water, and as a means of communication between the two places. It is constructed of iron, and crosses a rapid stream, known as Rock Creek. Its single arch measures 200 feet across, and is formed of two rows of pipes, of 50 inches internal diameter, resting on massive pillars of masonry. This is one of the boldest and most ingenious engineering undertakings of the day.

Baths.—As an addition to a house while building, nothing is so useful as a bath-room, for in these days of economy in almost everything, economy in health is becoming so well known and appreciated, that the desire for the means of health and cleanliness increase with knowledge; and all who can afford the luxury of a bath will enjoy it. Therefore, houses having this convenience, will certainly more easily let where such a convenience exists. The bath-room from time immemorial has been one of the most sumptuous luxuries of the east; and has existed in Europe for centuries, but has been confined to the few. The wonderful cures effected by the agency of water directed the attention of Mr. Bulwer Lytton to the establishment at Malvern, where he was so successfully treated, that he afterwards gave a little work to the public, expatiating on the benefits of the system in general, and the efficacy of private baths in particular. No sooner is a want established than skill is brought to bear upon it which rarely fails to produce the desiratum required. Mr. Phillips, of Skinner-street, Snow-hill, London, has manufactured a gas bath, displaying a great amount of ingenuity and skill which is worthy of every credit; neatness is combined with good workmanship and moderate prices. This bath can be heated in the short space of half an hour, an advantage of incalculable benefit in case of sickness, independent of its general use. The cost of heating this great convenience is quite nominal, 2d. It has also a linen warmer. We would recommend all builders to inspect this bath, and satisfy themselves of its great merit.—*Builder's Weekly Reporter.*

THE THEATRES.

French Plays.—During the last month the Zouaves, who founded the theatre at Inkermann, have been performing for a brief period at our Theatre Royal in some *petite* comedies. They are clever no doubt, but save for the associations connected with their theatrical career would scarcely prove attractive. Mr. Walter Montgomery, a young actor of considerable ability, but whose *forte* is tragedy decidedly, has also completed a brief engagement. Public expectation was greatly raised by the English and American press respecting Mr. J. Drew, a delineator of Irish character, now performing, and we were led to hope for a prototype of "Power." While awarding that gentleman approbation for what merit he *does* possess, we must frankly state, that he is not an Irish diamond of the first water. It may be fastidiousness, but we believe that actors *in this line* travel too far beyond the boundary of consistency, and seek to please by caricaturing rather than by genuine drollery. We live in too *progressive*, too *educational* an age to reconcile vulgar expressions, and a forced brogue, not to be equalled in the wilds of Connemara, with the position of a gentleman in society. We allude to *The Irish Ambassador*, and more *generally* than *specially*. In other characters the remark is, perhaps, not applicable to same extent, nevertheless in *all* to a *degree*. In plain truth, however, the delineation of Irish character as at present popular, is neither nationally nor individually creditable.

The Queen's Theatre.—If variety *be* charming, those who desire it have abundance to partake of in this favourite place of amusement, where comedy, tragedy, and music alternately hold their courts, and receive the approbation of an admiring multitude. The lessee, a host in himself—though his managerial occupations preclude his frequent appearance in public—invariably secures the best available talent from the London boards, and amongst those who recently appeared were Miss M. Oliver, Miss E. Jacobs, Mr. J. Clarke, and Mr. J. L. Toole, one of the most popular *comiques* of the day.

BANKRUPT BUILDERS.

Gustavus Hudson, of 47, Capel-street.

George Robinson, builder, Dalkey (was brought up for final examination on the 23rd ult. The assignees did not oppose, and admitted that the bankrupt had given a satisfactory statement. The case was ordered to stand over for a week pending the vouching of certain accounts).

Acknowledgment.—We acknowledge to have received from George Francis Train, Esq., patentee for Europe of "Street Railways," a full report in pamphlet form of the proceedings and banquet on the occasion of the opening of the *first* line at Birkenhead.

W. WARNE AND CO.

CALL the attention of Engineers and others to their PATENT MINERALIZED and VULCANIZED INDIA-RUBBER, in Sheets, and for Valves, Washers, Railway Buffers, Bearing Springs; Hose Pipes (delivery and suction), Flexible Tubings, Driving Belts, and to their improved Anglo-American FLEXIBLE CANVAS and INDIA-RUBBER PACKING, for Steam Joints and Piston Rods.

SOLE MANUFACTURERS OF THE
NEW PATENT MINERALIZED KAMPTULICON,
AND OF THE
MINERALIZED INDIA-RUBBER SOUNDLESS CARPET CLOTH,

Combining Extreme Flexibility, and consequent non-liability to cracking; Durability and Impermeability to Wet; warmth to the feet and softness to the tread.

SOLE MANUFACTURERS OF
WARNE'S NEW PATENT INDIA-RUBBER MATS.

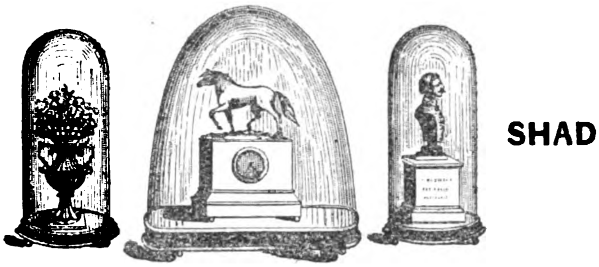
These Mats consist of Tubes of India-Rubber, of various configurations, placed vertically in contact with each other, and are far more efficient than any other description of Mat. No ordinary wear can sensibly affect them; they thoroughly clean the feet like a brush, and the dirt removed falling through the cells formed by the tubes, is not carried by the feet on to the floors and passages, which are consequently kept perfectly clean; and by removing the Mat, the accumulated dirt is easily swept away. They are also made with backs.

The Mats never clog, require no beating, and are readily cleansed by water. Unlike all other Mats, water in no way injures them, and it neither lodges on or is absorbed by them. Indestructible by damp or wet, these Mats, made to any shape, size, or thickness, are especially suitable for uncovered passages and out-of-door purposes.

The invention is peculiarly applicable for Mats for Baths, Conservatories, Laundries, Sculleries, Ships, Steamers, Omnibusses, Carriages, and Seats, also for Churches, &c.; and for Scrubbing Brushes for Decks, and Wooden and Stone Floors, and for Housemaids' Mats.

All Mats are marked W. WARNE and CO., Patentees, London. Orders received at the London Warehouse, 9, GRESHAM-STREET WEST, E.C.; or at the Factory, TOTTENHAM, N, MIDDLESEX.

GLASS SHADES



For the protection of Articles liable to injury from exposure.

Aquaria and Propagating Glasses, and Fern Cases;

A very large Stock of
CUT AND PLAIN TABLE GLASS,
Including Decanters, Wine Glasses, Carafts, Finger Glasses, Jugs, and Goblets, and every other article required for the Table. Also an extensive assortment of ORNAMENTS for the MANTELPIECE.
PLATE GLASS; PATENT PLATE GLASS;
SHEET and CROWN WINDOW GLASS; ROLLED ROUGH PLATE and HORTICULTURAL SHEET GLASS;
PAINTED, STAINED, and ORNAMENTAL WINDOW GLASS,
WHOLESALE AND RETAIL AT

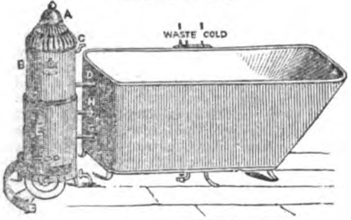
JOHN CARRICK'S,
5, MARY'S-ABBEY, DUBLIN.

THOMAS PHILLIPS,

55, SKINNER STREET, SNOW HILL, LONDON,
MANUFACTURER OF ALL KINDS OF

GAS APPARATUS FOR GENERAL DOMESTIC PURPOSES.

GAS BATHS.



FROM £12 AND UPWARDS.

Gas Stoves from 16s.

COOKING APPARATUS from £1, for Roasting, Baking, &

HALLS, CONSERVATORIES, PUBLIC BUILDINGS, &c., Heated by Gas or Hot Water.

Baths encased in Mahogany, Plain Wood, or Oak, and fixed on reasonable terms in any part of the country.

ESTIMATES AND PLANS GIVEN.

N.B.—Patent Safety Atlas Chandeliers, and all kinds of Superior Gasfittings; Outside Lamps, Posts, &c., for Public Buildings; Outside Reflecting Lamps, &c., for Shops; Portable Coppers for either Gas or Fuel; Superior Iron Tubes and Fittings for Gas, Steam, or Hot Water, &c.

A PROSPECTUS SENT FREE BY POST.

NEW GAS REGULATOR AND PURIFIER.

MESSRS. DEFRIES & SONS, of London, having taken out a Patent for the above new Gas Burner, we beg to announce that we have just made arrangements with them for the special sale of it.

This artistic and complete Burner is the most economical ever introduced, and is the admiration of all scientific men, on account of the various qualities it possesses.

First—It purifies the Gas by filtration, and allows no more Gas to pass through the Burner than is absolutely required to give a full, clear, and brilliant light.

Second—It effectually checks all undue pressure, and does away with the unpleasant flickering and noise caused by the same.

Third—The interior is anti-corrosive, and is impossible to get out of order, and when once set right it will last for years.

Fourth—This Burner answers with any common nib, and is unerring in its operation.

Fifth—It can be fitted by the most inexperienced hand.

Sixth—Though last, not least—it effects a saving of 25 per cent.

Price 1s. 3d. each.

GREGG AND SON (Sole Agents),
LAMP MAKERS AND GAS FITTERS,
18, UPPER SACKVILLE-STREET, DUBLIN

SITES FOR DETACHED HOUSES—BRAY LINE.

THE Lands of FOXROCK, GALLOPING GREEN, and KERRYMOUNT, are now being laid out for

DETACHED VILLAS,

and will be let at very moderate rents, in large or small lots, from half an acre upwards, at from £6 to £12 per statute acre. They command magnificent views of sea and mountain, are but two miles from Kingstown and Monkstown, and a few minutes' walk of Stillorgan station at one end and Carrickmines at the other, besides which a new station will shortly be established between them on the lands of Foxrock, whereby the entire of this beautiful building district will be within from two to ten minutes of railway accommodation.

A few superior Sites will be reserved for Terraces, with and without pleasure ground in front.

A large number of lots have been already let, some of the houses are nearly finished, and others in progress. Omnibuses will shortly ply daily between Foxrock and Kingstown for bathing, shopping, &c.

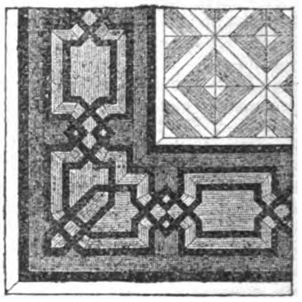
Lease for ever. Landed Estates Court title for most of the property; the rest is held direct from the Ecclesiastical Commissioners.

N.B.—Bricks, Stone, Sand and Lime on the property. Lithographed maps, showing the new roads, &c., may be had from

BENTLEY & SON,
110, GRAFTON-STREET, DUBLIN.

SOLID PARQUET FLOORS,

ARROWSMITH'S PATENTED,



From 1s. per foot. The "Wood Mosaic," 1 inch thick throughout (not veneered), for Halls and Reception-rooms, rendering them, if desired, available for dancing or otherwise A beautiful and intrinsic border for Turkey and other carpets, staircases, panelling, &c.; also for round the ALTAR and FONT of CHURCHES (being much warmer than stone), as at Escrick Church, York; St. Gregory's, Cheltenham; Mickleover, Derby, &c.

80, NEW BOND-STREET.

ENCAUSTIC TILE PAVEMENTS.

MICHAEL DOLAN, 39, LOWER MOUNT-STREET, DUBLIN. Fifteen Years at Minton and Co's, London. Estimates for Tiles, Cement, Labour, &c.

IMPERISHABLE TESSELATED PAVEMENTS.—H. SIBTHORPE AND SON, Agents to Maw and Co., are prepared to supply Designs for Floors of Churches, Conservatories, Entrance Halls, and Passages, with proper Workmen to lay them in any part of Ireland.

Various specimens may be seen at their Warerooms,
11 AND 12, CORK-HILL, DUBLIN.

PATENT ASPHALTE ROOFING FELT.

ELLIS AND CO.,
MALONE MILLS, BELFAST,
Manufacturers of
PATENT ASPHALTE ROOFING, SHEETING, INODOROUS, AND BOILER FELTS.
Sole Agents in Dublin,
Messrs. CAROLIN AND EGAN, 20, EDEN-QUAY.

ASPHALTIC ROOFING FELT, a light, clean, economical, and durable roofing, price 1d. per square foot. Samples and instructions may be had gratis in answer to letters from any part addressed to MAURICE BROOKS, IRONMONGERY, GLASS, & ROOM PAPER WAREHOUSE, SACKVILLE-PLACE.

PATENT SELF-REGULATING WIND ENGINE.

For Pumping, Grinding, Chaff Cutting, Sawing, or for Driving other Machines. This valuable invention is strongly recommended to the Nobility, Land Owners, and Farmers of Ireland. It is already extensively used in England and the Colonies; and the most satisfactory references can be given. For draining land it is invaluable; it has the following advantages over the steam engine—it costs nothing for fuel; will work safely day and night with occasional attention; it is easily and cheaply erected and kept in repair; a boy can start it, stop it, or alter its speed.

All particulars may be obtained upon enclosing one stamp to J. R. PEILL, Sole Manufacturer, 17, Park-street, Southwark, London; or to Mr. L. R. MOONEY, 26, Summer-hill, Dublin.

AN ADDITIONAL WAREROOM, for the better display of a large and varied collection of Marble Chimney Pieces and Fire Grates, has been added.

MAURICE BROOKS,
SACKVILLE-PLACE, DUBLIN.

The Dublin Builder.

Vol. II.—No. 24.

OUR THIRD YEAR!

Under circumstances highly pleasing, and influenced by feelings of sincere gratitude for the patronage and encouragement extended so far to the proprietor of this journal, we—as usual on the *completion* of one volume and prior to the *commencement* of another — take occasion to address a few observations relative to the *past* and *future* of our mission. When, at the corresponding period of the year 1859, we devoted a chapter to a similar purpose, we were on the eve of an important change—one, which if unsuccessful in its result, might have proved most disastrous—we allude to the introduction of *illustrations!* but cheered by your kind and encouraging voice, which constantly whispered in our ear Richelieu's motto of "Never say fail," we entered on the additional responsibility, and now—as all people will after a difficulty has been surmounted—we regard the event with much gratification. To it mainly must also in justice be acknowledged the rapidly-acquired popularity of the journal, the important advertisement display, and a largely increased circulation throughout the kingdom. At the time alluded to we promised that this department should be conducted "in a style commensurate *with resources at command*;" and with some confidence we now ask your opinion has it been so? That a *young* journal cannot *afford* to cope with old-established professional cotemporaries in the excellence or variety of its illustrations, or command the same extensive staff of eminent artists, we freely acknowledge; however, far from adopting an apologetic tone, we submit, that if a comparison be instituted between the manner in which our task has been fulfilled in *our* infancy, and others in *theirs*, or with "*the attempts*" of Irish journals that preceded us, we may in truth stand upon *our* merits without apprehension of suffering thereby. Avoiding a critical and tedious disquisition, or without indulging more than is legitimate in the egotistical, we refer with some just pride to the manipulation of the wood engravings in Nos. 13, 14, 18, and 20 respectively; all of which, but the two last especially, elicited much volunteered commendation at both sides of the Channel, and were pronounced—although *Irish* works—to be fully equal to the highest London standard.

Desirous, therefore, to render further facility for the display of Irish talent, we have placed several new subjects in the hands of our engravers, Messrs. George A. Hanlon and William Oldham, and faithfully promise our patrons that they shall, by the excellence of their production, materially contribute to the character of the Dublin Builder as an illustrated periodical. At the suggestion of valued friends we stepped somewhat out of the beaten path in presenting *lithographic* illustrations, but were pleased to find that they met with an encouraging reception. In Nos. 16, 19, 21, 22, and 23 were included supplementary lithographed sheets illustrating various buildings particularised in the Index, for the production of which we sought the best available local assistance, and believe that the gentleman to whom we entrusted their execution, Mr. W. Morrisson, fulfilled his task most creditably.

Honesty and independence of spirit have been our guiding stars in the conduct of the editorial department, and faithful observance of the motto, "merit to him to whom merit is due!" has alik characterised our criticisms of the deeds of friends and strangers. We have sought to combine in each publication instruction, variety, and originality—how far we have succeeded in doing so creditably it remains for you to determine; and though the responsibility has mainly devolved on the proprietor, acting in the double capacity of *financier* and *litterateur*, we must nevertheless, with all due respect, acknowledge the occasional assistance of a couple of valued contributors. It is our determination to adopt a similar course as long as we may be permitted to guide the helm; and should our effort to *maintain* the unanimous approving sentiments — substantially evidenced as having been so far *obtained*—prove successful, we shall be afforded additional subject for congratulation; and should even those strictures which, in the performance of a public duty, we are occasionally compelled to impose, raise up a *minority* of foes, we shall confidently fall back on the overwhelming *majority* of our friends, and console ourselves with the conviction so significantly expressed in the familiar quotation, *Mens sibi conscia recti.*

We are now on the eve of increased responsibility—viz, *fortnightly* publication; but "growing with our growth, and strengthening with our strength," we as cheerfully encounter it, as we have done others previously, especially as the public voice desires it, and that we are assured the same kind and generous spirit which has *hitherto* maintained us in a less important undertaking will steer us clearly through the difficulties of *this*. Unthinking minds may have chided us silently for our slowness—for not rushing recklessly into overwhelming expense; to rejoice for a while in congratulations for our "enterprise," and then consign ourselves to contemptible oblivion. But we have adopted, as results prove, the more prudent course,—we preferred to creep before we essayed to walk; we have invited friends to extend a helping hand to guide us through our childhood, and even *now*, though casting off the swathes of infancy, we cannot afford to dispense with our generous guardian—*the Public.* Still we most anxiously look for a continuance of—nay, for *extended*—patronage, and on our part no effort shall be wanting to render the journal in every respect a credit to this country, as with every sincerity we acknowledge that the English professional organs are to theirs. Various causes, amongst others the following, which we may briefly enumerate, prompt us to this step: first, because the majority of our subscribers being professionals, or otherwise connected with scientific and artistic matters, anxiously seek in a class periodical for the *earliest* intelligence of news, and reports of proceedings of institutes identified with their pursuits; and secondly, that to establish an exclusive organ, equal facilities should be afforded in the advertisement as in the editorial department in the matter of *engineering* and *building* contracts especially. To each of these most important considerations a *monthly* journal offers impediments; in the former, by publications of more frequent issue obtaining by a lengthened period precedence in recording "news," which afterwards becomes stale and second-hand; and in the latter, owing to the awkwardness of date, preventing the advertisement pages being adopted as extensively as they would be otherwise. To our minds even a *fortnightly* issue is not sufficient, and when we find ourselves justified in taking the additional step of publishing it *weekly* we shall not fail to adopt it. In conclusion, we must offer one word more of acknowledgment for *past* favours, and reiterate our hope that the continued patronage of friends and the public will ensure for us a prosperous *future.*

NEW CATHOLIC CHURCH, SAINT JOHNSTON, COUNTY DONEGAL.

This structure, which was commenced on the 4th of April, 1857, is now nearly completed, and will be consecrated on the 9th inst. The site is in front of the railway, as it passes from Derry to Strabane and Enniskillen, reposing quietly on the banks of the gently gliding river—

> "Where, in delightful streams,
> The Foyle, the darling of the ocean, flows."

And where, at each returning tide, this noble and majestic river, at its widest expanse

> "Hastens back so merry,
> To join the briny sea at Derry."

The church is built in the mediæval style; all its windows have *scoisson* arches. The plan is in the form of a Latin cross, and comprises in its arrangements, nave, transepts, chancel, porch, and sacristy, with a bell gable over the chancel arch. In the bell tower there is provision for two bells, which will be made of cast steel—the one to summon the congregation, and the other the *sanctus bell.* The entire length of the church is 109 feet 5 inches, and its greatest breadth 56 feet 5 inches, and from the ground floor to the apex of the roof, 50 feet. The character of the exterior is simple, and altogether free from unnecessary ornamentation. Its principal light is obtained from traceried windows in four gables or extremities of the cross. In the interior the chancel arch forms an important feature, the central part of which rises from pillared corbels of marble, with sculptured heads of the Apostles SS. Peter and Paul. The arches leading to the side chapels, which are placed in the north and south transepts, have plain soffits, relieved with polychromy. From the chancel arch six steps of polished stone lead up to the high altar, which has all the requisite arrangements of sedilia, piscina, credence shelf, aumbry, reredos, &c. The high altar is built of Caen stone, and rests against a reredos of the same beautiful material, from the *atelier* of Messrs. Barff and Co., Dublin The panels of altar and reredos are enriched with mosaic and enamel work, containing suitable monograms and ecclesiastical emblems. The reredos is divided into seven compartments, the central one rising higher than the others, and forming a canopy over the tabernacle, terminating in a cross. The bosses are carved into beautiful pieces of fruit, foliage, and flowers, on either side of the altar, supported on corbels, are elegantly executed carved figures, in Caen stone, of the Blessed Virgin Mary and St. Joseph. The roof of the church is open timber work, planed and rabetted with Gothic principals in the chancel, having their spandrils pierced with trefoil, and supported on struts resting on stone corbels, containing memorials of the Passion. The chancel roof is after being stained and varnished, in imitation of oak. The walls of same have been grounded with two coats of oil paint, to prepare them for future ornamentation. The chancel floor is laid with Minton's encaustic tiles, of various colours. A large space at the west door, and in front of the chancel, and all the passages in the nave and transepts, are filled in with Staffordshire red, blue, and buff quarries, the tiles next the chancel being of an octagonal form. The benches are stained and varnished. All the windows are filled in with tinted cathedral and stained glass, in lead sashes. The west window consists of four lights or bays, and is executed in tinted glass, with coloured borders. In the large circle of the tracery is the representation of an angel bearing a shield, with the holy name; in the smaller circles are monograms of St. Patrick and St. Columbkill, whilst in the upper circle is appropriately introduced the tiara and keys of the Sovereign Pontiff. The south transept window is of three lights, in the centre one of which is a full-length figure of St. Baithin, the patron of the church. He is dressed in the costume of a mitred abbot, having been second abbot of the monastery of Iona in Scotland, and the immediate successor and relative of St. Columbkille. In the other lights and tracery are sacred emblems and monograms. The north transept contains a beautiful design. In the centre light is a figure of St. Peter taken in a storm at sea, with the waves beating furiously against the sides of the ship, full of peril and danger, when a star suddenly appears, throwing its rays upon him and alongside the anchor, the emblem of hope. The saint is represented stretching forth his arms with joy on seeing it, and beneath the motto, "*Ave Maris Stella.*" From the top-mast is seen floating in the breeze the pennant, with these words, "*Regnum Dei et justitia ejus*"—"Seek first the kingdom of God and his justice." On either side is the lily, the emblem of purity, and the *Cœur de Marie*, and in the tracery are monograms and emblems connected with the life of the Virgin. The east window contains three lights, and is filled in with tinted glass of a geometric pattern, with ornamental coloured borders. In the tracery are introduced emblems of the Blessed Sacrament, the cusps being filled in with trefoil. The lancet windows in the chancel contain representations of winged cherubs. The stained glass has been all supplied by Messrs. Barff & Co., of Potter's-alley, Dublin, church decorators. A side altar has been erected in the east end of the north transept, richly ornamented in colour and gold. The centre panel contains a *Pieta* in *alto relievo*, with adoring angels on either side. The reredos is all of enamelled work, in blue and gold, with a very appropriate and beautiful design. This altar has been also supplied by the Messrs. Barff & Co. There is some carving on the spandrils and corbels of the west window, executed by Mr. Doherty, of Derry, a native artist. The entire masonry and tiling of this church was executed by Mr. Samuel M'Elwee, builder. Mr. E. W. Godwin, architect. There has been expended on its erection, up to the present time, upwards of £2,000, and £400 more are required.

Florence has decreed a statue to Dante. It is to be executed by Enrico Pazzi of Ravenna, and must be completed before the end of 1865.

A letter from Turin says—"Florence is making preparations for a grand exhibition, which is to take place next summer, and which is to bear the name of the 'Italian Exhibition.' The principal towns will co-operate by sums of money. The city of Florence gives 100,000 fr.; the Provincial Council of Florence, 30,000 fr.; Milan, 20,000 fr.; Leghorn, 10,000 fr.; and Pisa, 7,000 fr."

It is intended to apply next session to alter and enlarge the provisions of the act passed in the 58rd year of the reign of King George III., relating to Fitzwilliam-square.

LAW REPORTS.

Amongst the cases entered for hearing at sitting after the present Michaelmas Term we find the following, relating to disputes connected with our province:—John Farrell, builder, *v.* James Bolger; work and labour: Edward Henry Carson, architect, *v.* James Tyrrell; work and labour.

O'Reilly v. *Brennan.*—The arguments in this case, a new trial motion, have concluded. The action was brought by a builder to recover compensation for work done for the defendant at Bray. Mr. R. Armstrong, Q.C., was heard on behalf of the defendant in showing-cause against the conditional order. Judgment reserved.

BANKRUPTCY AND INSOLVENCY COURT.

In re J. F. Carson, a Bankrupt.—The bankrupt had been engaged in the timber trade in this city. The matter recently came before the court on application to re-open the final examination, which the late Judge M'Cann refused to pass, and the bankrupt was now four years out of business. Judge Berwick said that in looking over the schedule it appeared to him that the failure of the bankrupt was brought about by circumstances that might occur to any trader. He would not now, after the lapse of four years, refuse the final examination.

BANKRUPT.

John Kelly, of Ballymahon, Co Longford, builder and contracter.

INSOLVENT.

William Lynch, of Queenstown, carpenter.

ARCHITECTURAL MUSINGS.*

THE ORIGIN OF THE ORDERS.

Of erst, where orient summer warms,
  The gods with mortals blending,
Engendered grand and graceful forms,
  Supreme and never ending;
Poets climbed Parnassus high,
  And heroes cross'd the borders,
While angel artists cleft the sky,
  And shower'd down "the Orders."

A giant race in Dorus then,
  Of mind and mettle massive,
Fought like Titans, felt like men,
  Yet calm withal and passive.
The first descending shaft they clutch'd,
  They raised a stern recorder—
A work of art, of time untouch'd,
  The Herculean Order.

Anon, in dear Ionia, art
  With purer incense breathed,
And yearning for a nobler part,
  A glorious scroll she wreathed;
Robed with grace, from earth upborne,
  The world did accord her
That regal head-dress she has worn,
  The queenly Matron Order.

Then Corinth's inspiration shone,
  A quickening impulse giving;
Sculptors carved her *dead* in stone,
  And lithographed her *living*.
Conceptions, serial and sublime,
  With flowers were culled to border,
The *chef-dœuvre* of all time,
  The chaste Virginal Order.

Heirs of Greek and Roman sires,
  Brother artists, scan the story,
How the Goth has raised his spires
  From the *debris* of your glory.
Back to your Pagan prototype,
  And let our art awarders
Adjudge aright, and then outwipe
  The *fungi* on the Orders.

C. C. H——Y.

WOODLAWN LIGHTED WITH GAS.—The above splendid residence of the Right Hon. Lord Ashtown—the extensive buildings connected with which have recently been completed—has been lighted with gas. Messrs. Edmundson and Co., of this city, were employed to carry it into effect by means of their patent Gas Apparatus. The same firm have recently completed at Moore Abbey large additions to the gas works which they had previously erected for the most noble the Marquis of Drogheda.

---

* We desire to note that the compositions under this title are by a *working carpenter*, whose *animus* being evidently rightly directed, we insert them from motives of *encouragement*, and not as contributions of high poetic merit. (ED.)

RESUMÉ OF PROGRESS.

IN the fulfilment of our mission, it has been our constant care to present the readers of this journal with a periodical record of the various improvements—or constructive works, whether improvements or *not*—which have been in progress, not only in the metropolis, but throughout Ireland; it, therefore, appears suitable that we should—prior to the commencement of our *third* annual volume—glance over the pages of the second, which this number completes, and refresh the memory of our readers with a brief compendium.

Referring to the intelligence presented from the provinces, we must, as a preliminary, *again* make special mention of the courtesy of the several Irish companies—the Midland Great Western, the Great Southern and Western, and the City of Dublin Steam Packet; as also of the London and North-western, commanding the main artery from this metropolis to the world's emporium of science, art, and commerce—who, with a kindness not only to be appreciated by ourselves as an individual compliment, but by the public, which thereby acquires what might have been otherwise unobtainable, placed their respective lines at our service.

Keeping within the extended circle which the above title comprehends, we may note, that in the early portion of the current year we devoted considerable space to the special consideration of the all-important and all-engrossing topic, "THE WATER SUPPLY," as also in subsequent numbers to a detailed record of the various lengthened corporate discussions thereon, the evidence adduced before, and the able and conclusive report of, the Royal Commissioner, Mr. Hawkshaw, C.E. So far the questions of *quantity*, *quality*, and *feasibility* have been set at rest by the selection of the Vartry project, and it now remains for the citizens to contribute liberally towards the heavy outlay to be incurred in procuring a wholesome and abundant supply. Somewhat akin to this, "the drinking fountain movement"—which almost amounted to a universal *furore*—was extended to our metropolis and some of the provincial towns, effecting the philanthropic purpose in a degree, but unhappily not combined with that amount of artistic application for which great facility is afforded in such subjects. Desirous, however, that the fault of the public here should not lie in want of *good* example, we at some difficulty procured and presented various illustrations of such structures, executed with approval elsewhere. The mania has now partially subsided, and let us hope that architects will be thereby afforded more *leisure* for judgment in their designs, and that appropriate and artistic adaptations may be plentifully substituted for the present varieties of "mural slabs," partaking very largely of "churchyard fashions."

In the department of ecclesiastical work our chronicle has decidedly preponderated, and it is highly gratifying to observe that a complete revolution in taste and skilful arrangement of structures for the worship of the Most High, by all persuasions, is palpable throughout. Excepting in some remote districts, where probably professional services were, owing to limited funds, rather difficult of attainment, the barn type of church structures is being rapidly displaced by those of more orthodoxical fashion; but even there, may be found occasional recent tracings from the architect's hand, *par example* in a wild and somewhat difficult of access neighbourhood, situated in the Co. Mayo at Ballaghadereen and Charlestown, whither, *en route* to Ballina, Castlebar, &c., our steps were directed in July last. Of this class, perhaps one of the most—if not *the* most—important subjects for consideration is the restorative work now in progress at our venerable St. Patrick's Cathedral, suggested and matured through the munificence of a wealthy and philanthropic citizen, Mr. Guinness. Professionals naturally regard, and justly so, with interest any interference with a time-hallowed structure like this, especially if not directed by competent supervision; and communications—which we felt in justice bound to insert—were addressed to this journal, remonstrating on the misguided course pursued by the donor in not employing, *ab initio*, a qualified architect; nevertheless, though exception is taken to the guiding principle, due honour is cheerfully awarded from all quarters for praiseworthy spirit and intentions. We have already expressed *our* opinion explicitly on this abstract question, and we need not, therefore, dwell on it at present; but we presume, that as that gentleman has so much identified himself with the structure alluded to, he is equally prepared to become the recipient of *responsibility* for the result, as *merit* for the intention.

Still referring to this peculiar branch, we may remind the readers of this journal that our *chief* illustrations have comprehended some very noteworthy subjects, amongst which we may enumerate the wood engravings of Limerick Roman Catholic Cathedral (No. 13), Cookstown Parochial ditto (No. 19), SS. Peter and Paul's ditto, Cork (No. 20), together with lithographic views of the new Molyneux Church and Asylum (No 16), of the approved designs for St. Andrew's Parochial Church (No. 21), of Holycross Church, Tramore (No. 22), Laon Cathedral (No. 23), and others.

The aspect of our streets is certainly such as we must offer congratulations upon, whether in the improving architectural exteriors or our shop fronts, the widening of pathways, the removal of dilapidated structures and the substitution of a better, more tasteful, and more permanent class, the pavement and sewerage operations, and moreover the greater regard for sanitary considerations manifest throughout. Occasionally personally judging by contrast with other towns, not only in Ireland but throughout the kingdom, we have no hesitation in saying that Dublin is progressing in a ratio much greater than is generally imagined. Look to our public or our private streets, and compare not only the number of tenantless dwellings of 1860 with those of 1850, but see the enormously increasing value of property at every side—the south side especially; business houses in our *now* leading thoroughfares bringing large fines and heavy rents, which not very long ago were available for a comparative trifle, for an alleged reason of decline in the locality; antiquated and stunted façades paling before "ye moderne architects," and *municipal* progress almost immeasurable must be admitted. For one district the most comprehensive municipal improvements were confined to the neighbourhood of the Four Courts, where old and dilapidated structures, narrow lanes, &c., have been displaced to make room for a suitable addition to that building, and for the extension of Church-street, thereby ensuring a direct and spacious thoroughfare from our line of quays to the Broadstone (M.G.W.) terminus.

That the all-important desideratum of fitting and commodious *markets* will follow in the wake of progress we doubt not, but as the question is discussed more fully elsewhere, we abstain from dwelling on it in this chapter. With the exception of the National Gallery, the Kildare-street new Club-house, Harcourt-street Terminus, the Commercial Hall, St. Saviour's and St. James' Churches, it has not been permitted us to chronicle any other public work, excepting those already mentioned in this notice. Referring to railway extension, we believe it not improbable that at no very distant period the rapidly increasing traffic of the Dublin and Wicklow Company will necessitate important works at their Westland-row Terminus; and we may also note with pleasure that the long contemplated Liffey branch line is in actual course of construction, the contract having been recently disposed of to Messrs. Moore, brothers. What may follow from the completion of this we will not now state, though "*in our mind's eye*" we see a comprehensive scheme "looming in the distance." The practical application of horse tramways to our streets and thoroughfares will soon form an important item for consideration. It is said that a new bridge *will* be built at the Customhouse, that Carlisle-bridge *will* be either widened or rebuilt more spaciously, that the North Wall-quay *will* be extended, and another new graving dock built, but as these matters are still in "the womb of futurity" we must only await their advent with patience.

Wending our way hence to the suburbs, a new field for our notice—too extended, however, for this sketch—opens before us. Our record has embraced, at least to a considerable extent, particulars of chief items in the neighbourhoods of Rathmines, Rathgar—now virtually a wing of the city—of Kingstown, Dalkey, and Bray—all spreading with wonderful rapidity. Again at the north side, Clontarf, slower by a thousand degrees than the preceding, *yet* improving.

A passing word to the provincial towns, and we have done. We visited Belfast, Cork, Galway; in "progress" the former bears away the palm—her architectural appearance in structures either of public or a commercial class proclaim that her professors may fairly compete, when opportunity is afforded, with their *confreres* in any other town in the kingdom. The Ulster Bank—though not the work of a local practitioner—is nevertheless the most important recent acquisition to the town; moreover, sanitary measures receive special attention, though yet far from perfect. Cork is *slow*—very *slow*, considering the characteristic acumen of her people, and the world-famed ability of her art professors. *Two* public works—viz., the rebuilding of St. Patrick's-bridge and the new church of SS. Peter and Paul, with a couple of less important character, may be said to comprise the extent of her architectural undertakings. Slop and filth are prevalent, and her council should look to it, if they value health and longevity. Of Galway we should prefer to regard her probable *future* than her *present* reality, and therefore, with the intention of specially resuming a record of her progress when opportunity is afforded, we close.

This time twelvemonths we again purpose, God willing, to renew our periodical *resumé*, and if permitted to do so under equally gratifying circumstances, it will afford additional proof of the *value* of our mission.

THE HISTORY OF ARCHITECTURE.

(Read at Liverpool Architectural Society.)

The paper for the evening was "An historical and critical review of the various styles of architecture that have been practised in the world from the dawn of art to the beginning of the present century," illustrated by a coloured chart of the history of architecture; by Mr. Samuel Huggins.

He commenced by saying, that though the secretary's circular promised an independent paper illustrated by the chart, he had thought it best to reverse their relationship, and make the paper an illustration of the chart, which latter represented the origin and various successive transformations of the architecture of the Greeks, involving the rise, chronological sequence, relationship, &c., of the principal styles that have been practised from the dawn of art to the present time. It was embellished by various chronological tables: one, of the greatest ruling powers; another, of the principal architects; a third, of the great typical edifices in each style; and a fourth, of great events having an influence on architecture, which latter he had found so numerous as to show that, if the history of architecture was not identical with the history of the world, it was at least an appendage to human history, and organically developed out of it.

He began with the Egyptian style, the origin of which was lost in the night of time beyond the ken of historic record. To it belonged the oldest buildings on the face of the earth, irrespective of the Pyramids, which, though sublime objects, could scarcely be considered as architecture at all. Unlike the subsequent styles, which invariably manifested progress for a certain portion of their career, the course of Egyptian was one of decline, the oldest buildings being the greatest and purest in style. The Temple of Karnak was the oldest of temples, and perhaps the sublimest building ever reared by human hands. The Egyptian and Assyrian were the Adam and Eve of the architectural styles of the world. The Egyptian gave to the Greek some of its most beautiful elements and sublime characteristics, and shadowed forth the Doric order, while the Assyrian suggested the Ionic.

After describing the Assyrian style, which was chiefly illustrated by palaces, the remains of which had been, within the last few years dug out of the earth, he went on to the Persian, a style almost identical with the Assyrian, and which continued to flourish at Passargadæ and Persepolis till the fall of the Achæmenian dynasty and conquest of Persia by Alexander the Great.

The style of the early inhabitants of Greece was the Pelasgic, which, under the Dorians was there mingled with Egyptian and Assyrian elements till it grew into the Hellenic, or true Greek, the first appearance of which was at Corinth, under the Cyselides, in a form almost as massive as that practised in the valley of the Nile. This originated the archaic age of Greek art, which was followed by the more perfect age of Pericles. Of the style, as it existed at this time, he would only say, that every increase of knowledge went to confirm the belief that it was the most pure, noble, and perfect architecture that ever existed—an architecture in which the most intellect and refinement of feeling was embodied, and that involved the subtlest graces and excellencies ever expressed in stone. The noblest example of the style—the Parthenon embodied more intellectual beauty and æsthetic perfection of form and detail within the same compass than any other building in the world.

The period at which such architecture was produced, both classicist and mediævalist must allow to be the most illustrious epoch to which we could point in the history of architecture. As might be expected, it was otherwise illustrated; and the genius of architecture did not reach to so distinguished an eminence unaccompanied by her sister arts; not only by sculpture and painting, which were then in their zenith, but by poetry and "Divine philosophy." The Homeric period of the Grecian epic was long past, at the time in question, but it followed close upon that of Pindar and the Greek lyric muse; and it was contemporary with the glorious dramatic era of Æschylus, Sophocles, Euripides, and Aristophanes; rendered still more illustrious by the pure doctrines and bright example of the greatest philosopher of antiquity, who was then living in Athens—Socrates; while it heralded the philosophic age of Plato and Aristotle, and the no less brilliant era of Demosthenes and Isocrates.

The two styles, Greek and Etruscan, flowed together to form the Roman, into the defence of which, against recent depreciation, he warmly entered. The Roman style in the time of Augustus, its great period, was practised from the shores of the Atlantic to the Black Sea and Persian Gulph, and all round the Mediterranean, save Egypt. With the exception of the Egyptian, it was the only style of the civilised world; and, notwithstanding all that had been urged against it, he thought it was not unworthy of its great extent of practice. St. Paul's Cathedral, London, was Roman architecture as the Romans used it; and neither the Greek nor the Etruscan alone could have embodied such a composition, and no Romanesque, in which the two styles were fused into one, in the manner it was said the Romans should have united the styles, could have attained to half its grandeur.

After describing the style of the middle Persian Empire, which had an important bearing on subsequent styles, he entered on a description of the Christian career of architecture. Under the influence of Christianity, its hatred of all associations of Paganism, and its new requirements, the Christian Romanesque was generated, which style was no sooner formed than the Byzantine commenced its separation from it. The Byzantine style, as Hope says, originated in a wish on the part of the architects of Constantinople, after its separation from the Western Empire, of giving to the architecture of Christianity a form wholly different from that of Paganism. The Byzantine was the style of all nations of the Greek Church, or that remained of Christian in the East, and did not embrace the faith of Mahommet. After giving a full description of the style which, in course of time, became divided into several distinct branches, European Byzantine, Western Asiatic Byzantine, Armenian Byzantine, and Georgian, the latter coming down to near the present time, he went to the Saracenic group of styles, which were developed out of the Byzantine—viz., the Persian, the Syrian, the Egyptian, the Spanish or Moorish, and the Indian and Turkish; of which styles he gave an interesting description, characterising them as the most elegant and refined styles that have been anywhere practised, that had a great influence through the medium of the Crusaders on the decorative development of the Gothic. It was devoutly to be hoped, for the sake of the general interest of architecture in the world, that the increased intercourse with Europe would not further interfere with the practice of these styles, and prove an extinguisher of so much that was beautiful and poetic. Returning to the main stem of the history, he entered on the subject of the Gothic styles. From rude attempts of the various tribes of barbarians, who overthrew the Roman Empire, to imitate the edifices of ancient Rome in the erection of Christian churches, an entirely new system was originated, called Gothic, which for a while was all one nebulous chaotic mass. But in process of time it consolidated, branched out, and spread with the faith which called it into existence, into the different countries of Europe, where it exhibited local varieties according to the character and energies of the different races who adopted it. As the vernacular languages of modern Europe pushed themselves through the Latin as the exponents in each particular country of the popular thought, so in like manner the Gothic styles of architecture made their exit from the Roman. Of these Gothic styles, the Lombard was the first that became formed into an independent style, the German was the next, which was the finest of the round Gothic styles, and the one most worthy to stand as the representative and typical style of the class. He described the career of Gothic in France, England, Spain, Belgium, Scotland, and Ireland, and traced them through all their different periods to the time when their course was arrested by the Reformation and revival of classical art and other causes. He meant no disparagement to the Gothic system when he expressed his belief that it never could have come to us but through the artistic darkness and barbarism of the middle ages—for none but men who knew nothing of classic canons of art, and on whom Greek and Roman tradition had no authority, could have made so bold a departure from the architectural style which at the time was all but universal as the Lombards and other Gothic tribes made in the sixth and following centuries. Reverence for their great predecessors would never have suffered Roman artists to take sufficient liberties with the proportions of the Greek ordinance for the creation of a style so different in spirit and principle of composition as the Gothic. We were indebted to an outburst of barbarism in the fifth century, which destroyed the civilization of the ancient world, and plunged

Europe for ages into mental gloom, for the greatest system of architecture that had arisen since the Greek; and to the rise of a false prophet in the seventh, propagating his doctrines by the sword, and carrying desolation over the fairest countries of the globe, for another, which, if not so great, was still more elegant and refined. He went into a critical examination of various minor styles—Romanesque and mixed styles, such as the Sicilian, Italian, Gothic, Moresco, Neapolitan, and others; and then entered into an account of the revival of ancient architecture, the first dawn of which was in the 13th century, and traced the course of the modern Italian stream of art through the great period of the *cinque cento* to the present time. In conclusion, he said he should not have given so much attention to the subject but for the conviction that a knowledge of the development and history of styles was greatly assisting, if not absolutely necessary, to a right understanding of the principles of architecture.

The chairman having conveyed the cordial thanks of the committee to Mr. Huggins for his very interesting paper, Mr. Hay suggested that it should be published along with the chart, and expressed his opinion that together they would be the most important contribution to archirectural literature that had ever been made (applause).

Mr. Audsley said the paper Mr. Huggins had just read would be a hand-book for every architect in England.

The Chairman announced that the paper for the next meeting was by Mr. G. A. Audsley, on "Illumination and its Application to Modern Art."—The meeting then separated.

THE BATEMAN BANQUET, GLASGOW.[*]

THE Corporation, magistrates, and water commissioners of Glasgow entertained at a magnificent banquet in the Corporation Galleries Mr. Bateman, C.E, the engineer in chief over the Loch Katrine Water Works, as a token of their appreciation of his ability in carrying to successful completion his important task.

The Lord Provost, who occupied the chair, remarked that "the earliest works in which Mr. Bateman was engaged were in Ireland, and afterwards in England in the introduction of water into Blackburn, Kendal, St. Helens, Halifax, Wolverhampton, Stockport, Macclesfield, and other places, as well as Manchester. That in 1856 he undertook the charge of the Glasgow Water Works, surpassing not only all those named, but all similar works in the kingdom for grandeur and magnificence."

Mr. Bateman acknowledged the compliment at considerable length, and in the course of his statement he alluded to James Watt, and asked "what dead or living man can compete with him as a universal benefactor? The discovery, or rather the practical application of the steam engine, justly due to him, has done more for the civilisation of the world, for the interests of humanity, for the propagation of Christianity, and the maintenance of peace, than any other discovery that has ever been made; and though no man may claim so high a pedestal in the temple of fame, others of your sons, as Henry Bell, John Rennie, and Thomas Telford, have contributed in no small degree to the progress and prosperity of the age in which they have lived." And again referring to William Fairbairn—"a man he is proud to call father-in-law"—he pronounced him to be "unequalled in the present day for the originality of his genius, and for his contributions to mechanical science—distinguished in public for the extent and profundity of his researches, and in private for the excellence and amiability of his character." He then briefly sketched the history of the great project just brought to an issue, and detailed how in December, 1852, he "had the honour of being called in to advise with the Corporation" the various preliminary enquiries of the projects then under consideration, and his conclusion that Loch Katrine was "the best source of supply," but his disclaiming being the "originator of the idea." Describing the impediments that had to be surmounted, and the nature of the works, he said that "the country consists of successive ridges of the most obdurate rock, separated by deep valleys, in which it was very difficult, in the first instance, to find a way. No roads—no houses—no building materials, which would ordinarily be considered essential to the successful completion of a great engineering work for the conveyance of water—but it was a question of the geological character of the material which at once determined me to adopt that particular mode of construction which has been so successfully carried out. For the first 10 miles the rock consisted of mica, schist, and clay slate, close retentive material, into which no water penetrates, and in which, consequently, few springs of water are to be found. This rock, when quarried, was unfit for building purposes—there was no stone of a suitable description to be had at any reasonable cost or distance—no lime for mortar—no clay for puddle—and no roads to convey materials. Ordinary surface construction was, therefore, out of the question; but I saw that if tunnelling were boldly resorted to, there would be no difficulty beyond the cost and time required in blasting the rocks, in making a perfectly water-tight and all-enduring aqueduct—there would be no water to hamper and delay us in the shafts and tunnels, and little would require transporting through the country but gunpowder and drill iron. The aqueduct may be considered as almost one continuous tunnel. As long as the work continued in the primary geological measures we had no water, and even after it entered the old red sandstone, and where it subsequently passed through trap rock, there was much less than I expected, so that our progress at no part of the work was ever materially interfered with by those incidents which usually render mining operations costly and uncertain. The length of direct tunnelling on the Blairhulacan contract is about 4½ miles, the remaining length consisting of open cutting, afterwards arched and covered in, and aqueducts. The cost of materials used in blasting the rocks amounted to £13,934 11s. 8d., or about £2,000 per mile; and though the other contracts, on an average, were not as expensive, they, on the whole, amounted to about £30,000 for such materials. At the picturesque village of Sebastopol, as the miners call it, at the head of Loch Chon, several hundreds of the workpeople were accommodated. Provision stores, reading-rooms, a schoolhouse and church, and a resident medical man and schoolmaster were also provided for them. Happily, the deaths from accident, notwithstanding the dangerous character of the works, did not amount to half a dozen. All the works have been completed in less than four years from the commencement; and the rapidity of their execution, the success which has attended them, and the accuracy of their construction, are mainly due to the admirable manner in which my assistants and the contractors have jointly discharged their duty. To the resident engineers, and my principal assistants, I owe my special thanks, and not less to the men immediately under the inspectors of the works." Alluding to the extra cost of the works, the speaker reminded the company that the estimated expense for supplying *twenty* million gallons per diem was £540,000! but that the actual cost—viz., £700,000—produced *thirty* millions at least, and when slight alterations are made in some of the mills *sixty* millions will be obtainable. This is believed to be owing to the smooth glassy surface given by an internal coating of coal pitch. After referring to the saving effected by the purity and softness of the water in domestic articles, such as tea, coffee, soap, &c, Mr. Bateman concluded his most comprehensive and instructive speech in the following terms:—"I assure you I shall carry away agreeable associations—much that it would be pleasant to look back upon, and many friendships which I hope to retain. I leave you a work which I believe will, with very slight alteration, remain perfect for ages, which for the greater part of it is indestructible as the hills through which it has been carried—a truly Roman work; not executed, like the colossal monuments of the East, by forced labour, at the command of an arbitrary sovereign, but by the free will and contributions of a highly-civilized and enlightened city, and by the free labour of a free country. It is a work which surpasses the greatest of the nine famous aqueducts which fed the city of Rome; and amongst the works of ornament or usefulness for which your city is now distinguished, and will hereafter be famous, none, I will venture to say, will be counted more creditable to your wisdom, more worthy of your liberality, or more beneficial in its results than the Loch Katrine Water Works." He concluded by proposing "Prosperity to the City of Glasgow."

CHURCH STEEPLES AND LIGHTNING.

M. OCTAVE Pauwels, professor in the college of the Holy Trinity, at Louvain, in Belgium, has called attention to the frequency with which church steeples are struck with lightning. On February 19th, in less than two hours, and in an extent of 160 kilometres, eighteen steeples have been struck by lightning and burned. During the nights of April 14th and 15th, 1718, the lightning struck twenty-four steeples in Lower Brittany, in the territory between Landernau and St. Paul de Leon. It is a remarkable fact that those steeples which contained bells suffered the most. On the 11th of July, 1819, while the bell was ringing for a funeral, the lightning struck the church, killed nine persons on the spot, and wounded eighty-two. In thirty-three years, three hundred and eighty-six steeples have been struck in Belgium, and one hundred and three bell-ringers have been killed. Arago maintained that these facts only proved that bells rendered the steeples in which they were, more liable to be struck, and that it was by no means demonstrated that a great noise caused buildings to be struck which would otherwise have escaped. A distinguished *litterateur*, M. Méry, even maintained that prolonged discharges of artillery could make a cloudy sky clear. Professor Pauwels very reasonably urges that every method should be taken to protect steeples, since their prominence alone render them more liable to be struck. Then, too, the construction of churches in Belgium is such that in case of a shower the bell-rope becomes damp, and thus is made a better conductor, so that the electric fluid passes immediately down it and makes the bell-ringer the first victim.

FORTNIGHTLY ISSUE!!!

In accordance with previous notice, Subscribers and Advertisers are respectfully informed, that on and after the 1st of January, 1861, The Dublin Builder *will be published on the* FIRST *and* FIFTEENTH *of each Month, or, in case either should fall on Sunday, on the day preceding.*

Advertisers will favour with their orders referring to a Fortnightly, *not a* Monthly *issue as heretofore. All Accounts will be furnished terminating with the December Number, previous to commencement of the New Series, and attention is requested.*

Illustrations.—*The Editor will consider all subjects submitted for illustration.*

Vol. for 1860.—*Perfect Copies of the Vol. for* 1860, *with Wrapper and Index, may now be had at the Office, on payment of* 4*s.* 6*d*., *or per post,* 5*s.* 6*d.*

STREET ARCHITECTURE IN DUBLIN.

With a desire to record in a more especial manner than by mere notice the various works that are being executed in connection with the street architecture of this metropolis, we present herewith illustrations of two recently-erected shop-fronts for Messrs. Cherry and Shields, of Upper Sackville-street, paper manufacturers, &c., and Mr. George Tickell, of Mary-street, upholsterer and cabinetmaker, respectively. The former displays the lower portion of the establishment—which has a frontage four storeys in height in this leading thoroughfare—it alone being of an architectural character, after designs by Mr. Jones, architect; Mr. Pennefather, builder. The latter, which represents the entire façade, is also by the same architect; Mr. Whiteacre, builder; and has been erected at a cost of some £1,500. Our engraver has other illustrations of a similar class of subjects, metropolitan and provincial, in hands, which shall be presented in due course.

SUGGESTED ASSOCIATION FOR ARCHITECTS' ASSISTANTS.

A correspondent who subscribes himself "Sketch" addresses the following letter to the editor of this journal:—

"Sir,—Please give insertion in your invaluable publication to what must be the sentiments of not a few of a class, in whom I am sure you must take a lively interest – the architects' assistants of Dublin. It seems strange that in this city where the members of my particular branch of our profession number so many, no association of any kind has been formed for their mutual edification and improvement, especially when we consider how successful such associations have proved in London and in other cities—English and Scotch. Must it not, under existing circumstances, be probable that we shall fall far behind our contemporaries of these favoured cities? and will it be said of us that we have ourselves to blame?

"I feel prompted by these considerations to beg of *you* to aid us by bringing about the formation of such an association, at least by inserting this letter, which may be effectual in inciting some person better qualified than me to do the subject justice."

Our correspondent will, we are sure, do us the justice to believe that we would be the last to throw cold water upon a movement proposed for the benefit of any branches of the profession; but the suggestion now thrown out as regards Dublin would seem to be replete with impracticability; first, because the number of architectural *employees* is quite insufficient to maintain independently such an association; secondly, assuming that they even were sufficiently important numerically, we question the likelihood of a unanimity of purpose—a kindredness of spirit—so essential for the well-being and permanency of all similar undertakings; and thirdly, we apprehend that the *minority* of the profession—the assistants—will hardly achieve what the *majority*—the masters—seem to have hitherto found impracticable. As an amendment, however, to the proposition we would move, that "in any professional institute or association that may hereafter be formed, the claims of the architects' assistants—who shall be deemed worthy of admission—to occupy a suitable position at the meetings, should be duly considered."

OFFICIAL VANDALISM.

We are much concerned to see that our truly handsome post-office structure—the *chef-d'œuvre* of the late eminent architect, Francis Johnston, R.H.A.—is being tampered with externally, and in its most prominent feature, by the post-office authorities, for the purpose of acquiring an additional space of some 8 feet in front. As if in dread of public expression of opinion, the contemplated change was kept a profound secret until *all* was *decided on*, and the contractor at his work. There is, of course, *now* no time for remonstrance, but we are still left the alternative of *protesting*—which we do in unqualified terms—on the barbarism of the innovation, and the destruction of one of the chief features of the noble portico—viz., the inner vestibule or arcade. With that excellence of arrangement that always characterised the plans of the distinguished architect in question, this recessed space was evidently *specially* designed, as well for architectural effect as for a relief to the thoroughfare, of which the portico actually forms a portion. The dispensing with such space, therefore, *may* prove an acquisition to the post-office, by enabling the receivers to be extended, but it will be at the sacrifice of *public convenience* to a serious extent. Who that has passed in the vicinity of this building at those periods limited for post, has not witnessed the *crushing, jostling, and squeezing,* that takes place? but now, with considerably diminished space, an increasing rush of people, and the necessities of a populous thoroughfare to be likewise provided for, we prophesy that the annoyance will be increased ten-fold. It *may* be in contemplation to extend the pathway outside the columns, and disfigure the street. Probably we shall next hear that the portico is doomed to be built up *altogether!*

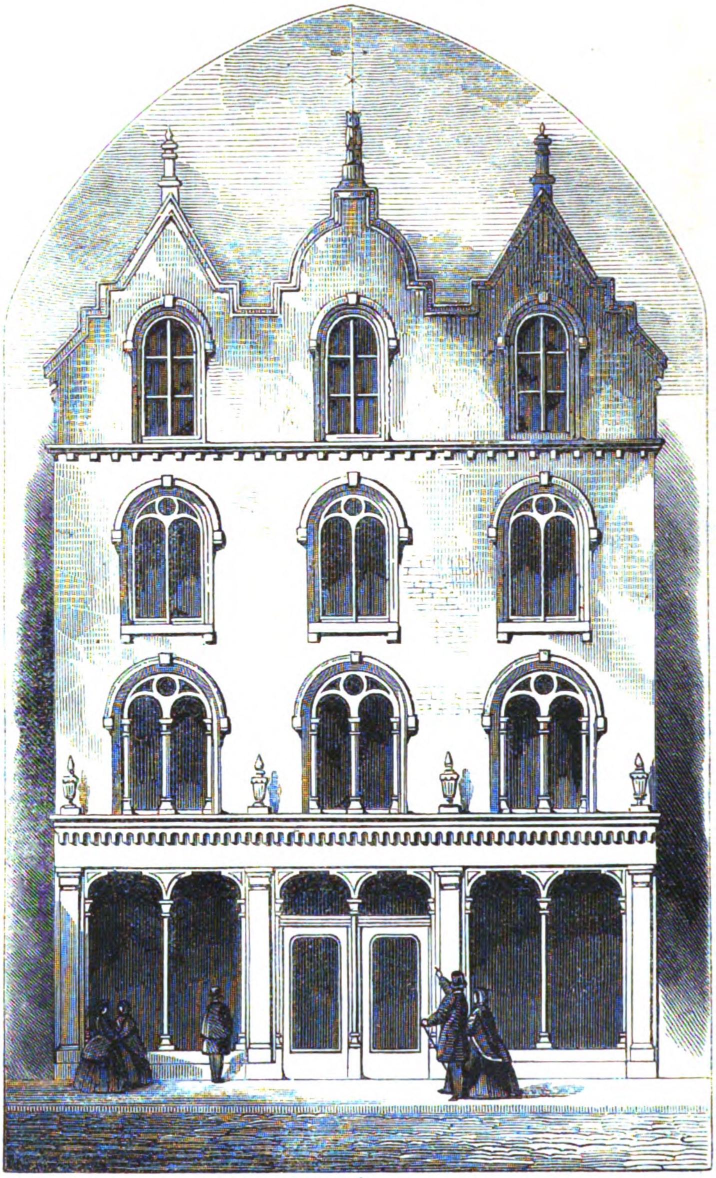
REMUNERATION TO PROFESSIONAL WITNESSES.

Anomalous as is generally the position of an architect in regard to his *legal* rights for professional remuneration, it is peculiarly so in the matter of attendances at court by subpœna. Occasional cases of course present themselves, wherein he may be enabled to make his own terms, or even where the considerate spirit of a client will relieve him from the trouble by volunteering a consistent offer; but as a general principle, and in the absence of these advantages, an architect experiences extreme difficulty in obtaining a more special regard from a taxing master, from whose *veto* we believe there is little chance of redress, than any other non-professional individuals—the value of whose time and services are estimated alike by the learned functionary. A *subpœna* is all powerful in its character, and equally applies to the most accessible or the most remote distances in our island; if disregarded, attachment for contempt may follow, and we need not remind our readers of the responsibility attendant thereon. It happens to have been our lot to have personally noticed some instances, not only of hardships to the witness, but flagrant injustice and abuse of authority on the part of the rigid administrators of the law, but of a recent one in particular we would make special mention. A member of the profession in Dublin, enjoying a remunerative practice, and to whom of course time was equivalently valuable, was required by subpœna to attend a trial relative to a building case, and give evidence on which the result mainly hinged, in a town only 150 miles distant, and occupying *fifteen hours'* travelling time alone for *each* journey. Owing to circumstances now unnecessary to detail the period that elapsed from his departure to his arrival was *only* ten days, and for this the taxing-master—of course duly considering time, services rendered at court, and inspecting disputed works, hotel and travelling outlay—most graciously awarded to this *mere* architect a sum of *five pounds!* and for expenses *three pounds!* total eight pounds!! *or about the costs out of pocket, if so much!* In attending court in the metropolis it is much the same. Architects in vain say they are entitled by the rules of the profession to £3 3s. per diem *(where is the institute to maintain the right?)*, but if a whimsical taxing-master say 10s. 6d. per diem as the *legal* allowance, where is the redress?

KINGSTOWN WATER WORKS.

It has been announced by public advertisements that application will be made to parliament next session for a bill to enable the construction of the several works required for the more effectual water supply of this highly-important township, and which comprehend the enlargement of the Carrickmines reservoir, the abandonment of the Foxrock reservoir, provided for by the Act of 1859, the varying of the line of conduit, and the formation of one from a point 350 yards south of the stream running into said proposed Foxrock reservoir, to the junction of the Carrickmines and Cabinteely roads, &c.

STREET ARCHITECTURE IN DUBLIN—SKETCH No. 1.



NEW WAREHOUSE, MARY-STREET.—Mr. George Tickell, Proprietor; Mr. Jones, Architect.

PROPOSED NEW MARKETS.

At length the initiative has been assumed in endeavouring to rescue this metropolis from the palpable disgrace it has hitherto been labouring under as regards "market accommodation," and a company is *about* to be established, with special Act of Parliament, "to erect and maintain *two* new general public markets and market places," for the north and south sides respectively. It is proposed that the one should occupy a site adjoining Cole's-lane, in the Parish of St. Mary, and the other in the vicinity of the Castle, and Parish of St. Bridget. The importance of such a project for the sanitary welfare and the comfort of our citizens cannot be too highly estimated, and we have every confidence in the promoters developing the scheme, in all its details, in a manner which will redound to the credit of the city and its corporate authorities. In earlier numbers of the Dublin Builder we drew attention to the desirability of such a step, and now that preliminaries have been actually commenced, we shall not fail to chronicle the progress of the movement, and illustrate the structural arrangements.

The patentee of Breach's fire-escape apparatus has been exhibiting it at the Rotundo for several days in succession.

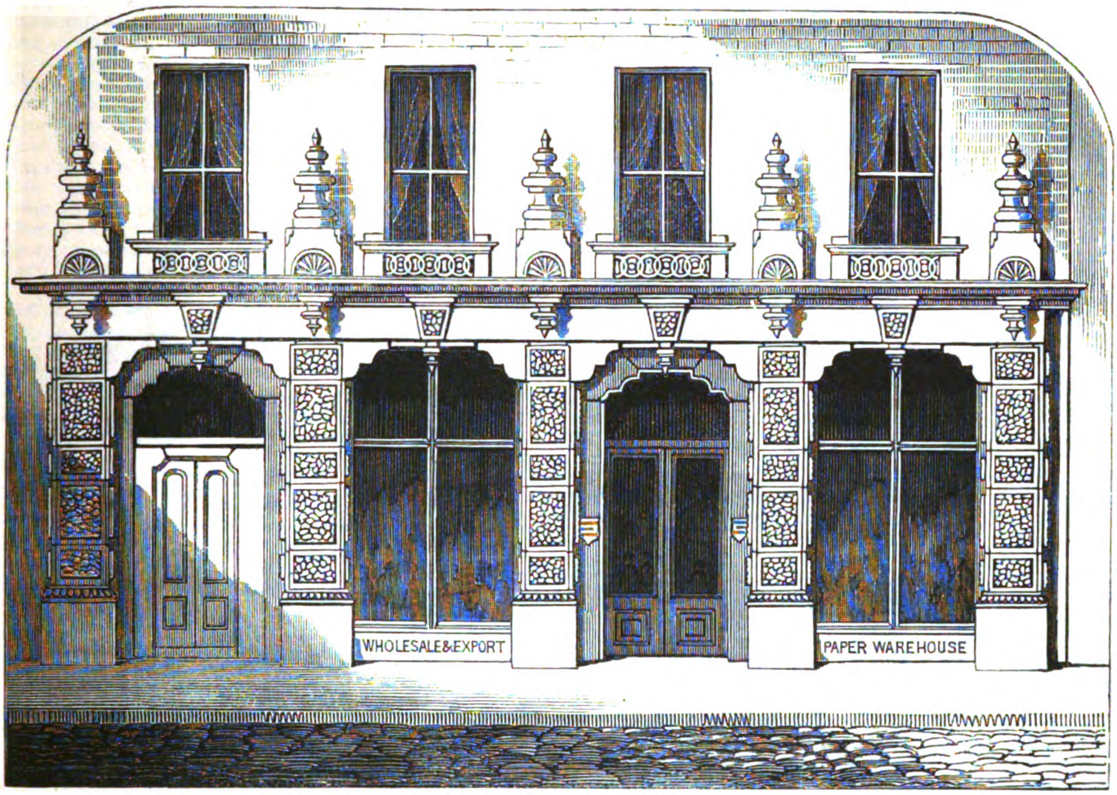
THE NORTH WALL NEW GRAVING DOCK.

A correspondent takes exception to a paragraph in last number with respect to the capacity of this structure for docking the Kingstown and Holyhead steamers, and says, "it is amply large to dock much larger steamers than those you mention, being 400 feet long, 80 feet wide, and 23 feet deep. The reason that the *Leinster* was not docked was, that they were afraid that the floats of her paddles would come against one of the broad altars, unless the vessel was trimmed to a nicety, and to settle the matter a trifling alteration is being made in the dock." We are also reminded that the cost was £63,768 9s. 10½d., instead of £100,000. [The paragraph in question was a quotation from another journal, and did not emanate from this.—Ed.]

OBITUARY.

We regret to have to record the death, which took place on the 25th ult., of Mr. William Moyers, of South Richmond-street, an old and highly-respectable builder, who during his lifetime was engaged on numerous important contracts.

STREET ARCHITECTURE IN DUBLIN—SKETCH No. 2.



NEW SHOP FRONT, UPPER SACKVILLE-STREET.—Messrs. CHERRY, SHIELDS, & CO., Proprietors; Mr. JONES, Architect

THE SLIGO TOWN-HALL.

GOVERNMENT has promised a contribution, from the Reproductive Loan Fund, towards the erection of the new town-hall in Sligo. A considerable sum will also be raised by subscription. Mr. M'Donough, M.P. for the borough, gave £100; the Mayor, Henry Lyons, Esq., £50; the ex-Mayor, Mr. M'Carthy, and Mr. Woods, each £20. At a meeting of the Corporation on the 15th ult., the Mayor proposed that other buildings, such as the post-office, the excise-offices, &c., should also be grouped with the town-hall, and stated that a plan had been prepared. Mr. Woods objected to looking at any plan at present, and said he lately saw an application for payment for one that *was not worth one penny;* that they should get the united intellect of the kingdom, and let the successful man be paid fairly. A discussion then took place relative to the responsibility to to be incurred by the Council in entertaining any plan from a local architect. Councillor Woods said the site ought first to be decided on, and would give £40 for a prize. The Mayor said £20! would be quite enough, and Councillor Phillips suggested £10!!! Mr. Caldwell, jun., architect and builder, entered the room, with a plan to submit to the Council. Mr. Woods objected. Mr. Caldwell said, "I do not intend to charge you anything for the plan; I brought it merely to enable you to form a proper opinion as to what a town-hall should be; (to Councillor Woods) *I fear not competition.*" Councillor Phillips—"I feel proud that we have men in Sligo capable of furnishing us with plans." Mayor—"If we shut out Mr. Caldwell *it will be very wrong.*" Councillor M'Carthy—"I move that Mr. Caldwell's plan be accepted." Seconded by Councillor Phillips. Plan accordingly placed on the table. Councillor Woods—"You will find that the feather end of the wedge is now got in!"

We are pleased to see that the committee appointed to distribute the Taylor Fund have, in consideration of the commendation of the judges, awarded to Miss Mary Alment for a landscape in oils of "a roadside in summer" (Stillorgan), and to Mr. Henry Crowley for a view of "the town and harbour of Wicklow," each a prize of £3. These pictures were favourably noticed in our review of the works sent in competition, and were not amongst the *original* prize works.

LICENTIATES IN ENGINEERING, T.C.D.

TRINITY TERM, 1860.

Examination for Diploma—Benjamin Patterson, William Crawford, Robert Duke, Pemberton Tudor, Herbert Ribton, Richard Symes, Robert Denny.

Special Certificate in Chemistry and Geology, Practical Engineering, and in Practical Mechanics and Physics—Benjamin Patterson.

Special Certificate in Practical Engineering, and in Practical Mechanics and Physics—William Crawford.

The contract for the new railway station at Foxrock, on the Bray line, has been given to Mr. John Cunningham, the builder of the Harcourt-street Terminus. It is to be completed for opening on or before the 1st of next May.

Mr. Colclough has completed an extension of his Coach Factory in Duke-street. The contractor for the work was Mr. Rosborough; superintending architect, Mr. Gribbon.

Scribblestown House, Co. Dublin, is being fitted up as the residence of the Dowager Lady Clanmorris, extensive improvements thereto being in progress under the inspection of Mr. E. P. Gribbon.

Messrs. Alex. Thom and Sons, the eminent government printers, have just completed an addition to their extensive buildings in Abbey-street. Architect, Mr. E. P. Gribbon; builder, Mr. Andrew Halston.

Messrs. Milner, of Phœnix Works, Liverpool, have offered a prize, to be competed for by the students of the Architectural Association in that town, for the best full-sized designs for doors for their safes, of the respective sizes of 28 in. by 22 in. in one leaf, and 66 in. by 54 in. in two leaves.

The old established foundry of Messrs. S. Vincent and Son, in Church-street, has had the front portion recently rebuilt, with a façade of unique and imposing character, which is well seen from the Quays since the removal of the houses for the extension of the law courts. This building reflects credit on the tasteful proprietors together with their architect, Mr. Gribbon, and builder, Mr. S. H. Bolton.

The Dublin and Wicklow Railway Directors, responding with a characteristic liberality to the request of the inhabitants of Kingstown in the vicinity of Albert-road, have determined on establishing a station at that point, which is midway between Sandycove and Dalkey.

STREET DISFIGURATIONS.

We desire to direct the attention of the City Surveyor to the unsightly projecting shop-front now erecting at 34, Great Brunswick-street, and to enquire if it is to be permitted to *remain* so. It extends beyond the general range of buildings in that important thoroughfare some four feet, and though it may be a general assumption that the base course of the area railing defines a boundary, it has nevertheless in a recent instance in this city been held not to do so; and the owner of a house in Merrion-square, after incurring much expense, was compelled to remove a similar obstruction, though not interfering with the pathway. Does not the same law—if any—apply alike to all streets within the metropolis?

The Metropolitan Building Act (London), 8 Vic. c. 84, sch. E, referring to "*projections*," says:—"In streets or alleys of a less width than 30 feet, *any shop front* may project beyond the external wall to which it belongs for five inches and no more; and every cornice of any such shop front shall project 13 inches and no more; and in any street or alley of a width *greater than thirty feet*, any shop front may project *ten inches and no more*, and the cornice may project for *eighteen inches* for the external walls but *no more*." That the excellent provisions of this act do not apply to Ireland is much to be regretted; nevertheless, here is a precedent, and why should not our corporate authorities, who are endowed with certain powers, at once follow it?

KILKENNY ARCHÆOLOGICAL SOCIETY.

At a recent meeting held in the society's apartments—the Rev. Charles A. Vignoles in the chair—several new members, including Lady Orde, Mr. Hill, architect, Cork, &c., were admitted. The treasurer's accounts for the year 1859 showed a balance of £87 odd in favour of the society, arising from "an unusually large number of life compositions," and despite the legitimate income being reduced more than £20 less than previous years, owing to defaulting subscribers. It is proposed, from prudential motives, to hold the meetings quarterly, instead of bi-monthly as heretofore. The Revds. James Mease and Graves, Lord James Butler, and Rev. Philip Moore respectively presented donations, and Dr. Prim exhibited an ancient illuminated patent "of English Liberty," from King Henry VI., in 29th year of his reign, to Thomas, grandson of William O'Neill. A fragment of the great seal of Ireland was attached to this document. Mr. Prim presented a copy of *Saunders's Newsletter*, of September 1, 1798, as did Mr. Waters one of *The True-born Irishman*, of March 13, 1804. Dr. Hemphill presented a Nuremburg jetton, found in that town.

FIRES!—PROCRASTINATION!

The proverb that "delays are dangerous," seems to have been fully verified by an event occurring in this metropolis during the last month, wherein, owing to a flagrant neglect of precautionary measures for the fearful casualty of *fire! three* human lives were lost under circumstances most painful to contemplate. As already notified by our cotemporaries, a fire broke out on the morning of Sunday, the 11th ult., in the old Kildare-street Club-house, and almost in a twinkling the valuable contents of the building, excepting the plate and wines, were totally destroyed; an event, however unfortunate, would nevertheless be reconcileable as a commercial loss, were it not for the calamitous accompaniment of *death* to our fellow-creatures. The *notorious* defectiveness of the water supply, the *miserable* exhibition of bungling at the engines and hose, the absence of system and of a *head* to conduct the operations, were most apparent, and before the engines were rightly at their work, half, if not more, of the building was destroyed, and three wretched inmates reduced to shapeless charred masses. As may have been expected, the morning journals, *after the fire*, teemed with suggestions—some evidently dictated by truly philanthropic notions, others savouring very strongly of a desire to appear in print; the citizens and their corporate representatives still discuss "the propriety" of providing a sufficiency of fire-escapes and a qualified brigade; but pending the suiting of "the action to the word," fires *again* occur, property is destroyed, and *people lose their lives*. Let us hope, however, that some practical energy of purpose may be forthwith infused by these fearful examples into the authorities, and that Dublin will soon have the same facilities for lessening the destructive results of fire, both to life and property, as have London, Manchester, Liverpool, and other towns. While referring to this painful event, we take occasion to testify our unqualified admiration of the heroic conduct of Mr. Hughes, the book-keeper of the club, who, by a superhuman effort, reached the roof, climbing by a spout to the granite cornice, at a height of some 60 feet from the ground, and, in the face of the roasting flames, dragged two females after him, and thereby saved them from *certain* death at the almost *as certain* risk of his own life. The glorious act has been gracefully acknowledged by the Viceroy in a personal visit, and we doubt not that a *substantial* reward of merit will be accorded by the public to one who may well be designated "a hero of an age."

THE COMING EXHIBITION OF 1861.

As already announced, an exhibition of works of Fine and Decorative Arts will be held early in May, 1861, in the Agricultural Hall of the Royal Dublin Society, and the following syllabus of the departments has been issued by the committee:—

1. Paintings by the Ancient Masters.
2. Paintings by the Modern Masters.
3. Water-Colour Drawings.
4. Engravings and Etchings, Ancient and Modern.
5. Sculpture, Casts, and Models.
6. Architectural Models, Photographs, and Drawings.
7. Carvings in Wood, Ivory, &c.
8. Works in Wax and other Plastic Materials.
9 Painted Glass.
10. Textile Fabrics.
11. Ancient and Modern Glass Wares.
12. Ancient and Modern Pottery.
13. Drawings and Engravings Illustrative of Wall Decoration.
14. Furniture.
15. Ornamental Works in Metal.
16. Photographs.

PROCEEDINGS OF ARCHITECTURAL BODIES.

The Royal Institute of British Architects held the first meeting of the session on the evening of Monday the 5th ult., Professor Cockrell in the chair. A letter from Mr. Tite, M.P., offering a permanent annual prize of *ten* guineas to be given in books or money for the best set of sketches in the Italian style of architecture (of Palladio Sonsovino, Vignola, Inigo Jones, Sir Christopher Wren, Perrault, &c.), for such buildings as churches, town-halls, railway termini and stations, public offices, &c. A vote of thanks was accorded to various donors. The subject of architectural examination was then referred to, but on the motion of Mr. Godwin the consideration was postponed till 10th instant. Another meeting was held on 19th ult.

The Architectural Association commenced its sessional labours with great *eclat* on the 25th October, when Mr. Roger Smith, president, delivered, in presence of a large assemblage of members, visitors, and ladies, an inaugural address, embracing a comprehensive resumé of "the occurrences and features of the past twelve months that are of general interest to the profession;" a glance at "the battle of the styles;" at some recently erected architectural works, especially the northern school of St. Martin's in the Fields, and the new church in Margaret-street; a notice of Sir Christopher Wren; of the three metropolitan architectural societies; the subject of architectural examinations; the deaths of Earl De Grey, Sir Charles Barry, Messrs. Stephenson and Brunel; the relations between the association and the institute, &c. Other meetings of this truly energetic and praiseworthy body have been subsequently held.

At the Architectural Society of Liverpool on the 31st October, Mr. James M. Hay, president, in the chair, the council awarded a prize to a drawing made of West Derby Church from actual measurement. A discussion then followed on the subject of the voluntary professional examination, and a communication, of which we give an extract, was read from Mr. H. P. Horner.

"As regards the peculiar character of our profession, it must be remembered that it is essentially a *fine art*, while dependent for the *realization* of its conceptions on mechanical means; but the conceptions themselves, which constitute the art, are primarily independent of these means, though in so far concerned with them as truthful and consistent physical structure must ever wait upon sound and satisfactory architectural design. This admitted, and a competent theoretical knowledge of the principles of construction on the part of a designer being thus supposed (and without this he could scarcely design at all), it seems to me, that the practice of architecture takes its place with that of the other kindred arts, sculpture and painting, and can no more be made the proper subject of a license or diploma than could these."

The chairman, in the course of some pertinent remarks, stated that—

"This examination will compel the student to undergo a long and tedious preparation; for, although architects generally may be more or less acquainted with these subjects, it is a very different thing to be called upon to answer every question at a moment's notice; and the best men may not always be the most successful in their answers. Still the result will be to improve the education of the architect."

Moreover that—

"The greatest care and caution must be adopted in introducing the system—liberal treatment and fair play—so that the minority excluded may neither be formidable in numbers nor ability. Anything like stringent measures or severity at the outset will defeat the object aimed at."

Mr. Boult thought "there was an inconsistency in Mr. Horner finding fault with the curriculum because it did not embrace any test of fine art in architecture, and then saying that such a test was impracticable," and moved resolutions in favour of ' the diploma."

Mr. John Hay and Mr Wightman followed on same side, and Messrs. Frank Howard, Andsley, and Callihan in the *negative*. Mr. Wightman proposed and Mr. John Hay seconded the following resolution, which was carried *nem. con.*:—

"That the local examinations, especially the elementary ones, be conducted under the auspices of the respective local architectural societies."

[*Where is the local architectural society for Dublin*?—Ed.]

The Glasgow Archæological Society has also met and elected office bearers, of whom Mr. James Smith, F.R.S. (of Jordanhill) is president; Mr. John Honeyman, jun., architect, honorary treasurer; and Mr. W. Ewing, honorary secretary. The president presented a few particulars relative to the "Pre-Historic Antiquities of the west of Scotland," and Mr. Smith read a paper on the old church at Renfrew.

The council of the Institution of Civil Engineers, London, offer premiums for the following new list of subjects, viz.—

On the Effect of Sluicing, in removing and preventing Deposits at the Entrances of Docks on the Coast and in Tidal Rivers.

On the Measure of Resistance to Steam Vessels at high Velocities.

On the Form and Materials for Floating Batteries and Iron-plated Ships (Fregates blindees"), and the Points requiring Attention in their Construction.

On the Initial Velocity, Range, and Penetration of Rifled Projectiles, and the influence of Atmospheric Resistance.

Description of Street Railways and Carriages, as used in the United States of America, in Paris, and at Birkenhead, with the Results.

On the application of the Electric Telegraph to Railway Train Signalling.

OLD AND MODERN ESSEX-BRIDGES.

In the year 1676 Sir Humphrey Jervis began to build old Essex-bridge of the stones of St. Mary's Abbey, and the structure then consisted of five semi-elliptical arches and two smaller semicircular ditto at southern end. The carriage-way was 20 feet 5 inches in width, independent of a pathway about 9 feet 6 inches wide, and the summit of the pavement was 26 feet 8 inches above low water mark. An equestrian statute of King George I. occupied a pedestal at the western side, resting on a special pier. It is related that about eleven years afterwards a violent storm, at E.S.E. point, arose, causing the Liffey to overflow the streets and ascend to the parlour floors of the houses. At this time a hackney-coach happened to be passing over the bridge, and a pier was carried away by the floods, precipitating coach, coachman, and horses, all swept down to the watering-slips, the man clinging to the box as long as he could, but was drowned in the current. In 1751 the repair of the bridge was so bad that for nearly four months it was closed to public traffic, until the late Mr George Semple, architect, accidentally meeting Mr. Prior at dinner at the then Archbishop's of Dublin, was, owing to the representations of that gentleman to the Lord Mayor, induced to undertake its temporary repair. This task was accomplished successfully in ten days, at a cost not exceeding 100 guineas, the estimated sum. We may here digress to mention, that at this period Mr. Semple was engaged in building Patrick's Hospital, two houses for the Rev. Dr. Leigh in Capel-street, one for the archbishop, another for Colonel Ram at Gorey, &c. Subsequently, however, the requirements of the city demanded the total rebuilding of the bridge, and prior to engaging on that important work, Mr. Semple went to London to procure the best books on bridge building, plans, &c., and he describes his "indignation and sorrow at finding an art of such public utility so shamefully neglected." In commencing preliminaries for the foundations of the new bridge, various impediments presented themselves, owing to the composition of the bed of the river, and other causes, which, to use the architect's own words, "threatened to frustrate his intentions of building a bridge that should last as long as the little adjacent mountain called the *Sugarloaf*, as he had determined." Again, referring to the want of practical example in the laying of foundations, and being obliged to have recourse to books for information as to the *modus operandi*, he says, "They told me to form an *enclosure*, but as well might they tell a man that to measure time he must make a clock." In May, 1752, the architect again went to London to procure advice and utensils, and was greatly disconcerted at finding that those engineer friends from whom he sought information relative to the use of the coffer dam, not only were unable to give him any, but assured him the method "would not answer his purpose." In this state of disappointment he relates, as a significant coincidence, his accidentally finding, at Dover Hill, a leaf out of a schoolboy's book, with the following caution:—"*The more positive thou art, the more derided wilt thou be if thou miscarry.*" However, nothing daunted, and collecting *all* the information he could obtain, he returned to Dublin, *via* Liverpool, accompanied by some labourers. Without particularizing all the details connected with the construction of the foundations, we may state, that they were effectually formed, the chief impediment being a strong boiling spring at the north side, that for a length a time defied all skill, but was finally vanquished. Once these primary obstacles were overcome, all went on smoothly, and on the 1st of November, 1754, the centres for the two southerly and for the centre arches were being put up. On the 8th of May following the Lord Mayor and Sheriffs drove over the bridge, and on the 10th it was open for public traffic, in two years and eighty days since the old was closed. The superstructure affords a carriage-way of 31 feet, with pathways at either side, 8 feet wide, and has balustraded parapets. The total length is about 200 feet, and there are five water-ways, the centre being 46 feet, the two adjoining 41 feet, and those next the abutments 36 feet span. Considering the circumstances attending the erection of this structure, it must be conceded that Mr. Semple displayed much ability.

RESTORATION OF ST. MARY'S CATHEDRAL, LIMERICK.

Our readers have been already apprised through the columns of this journal that the venerable relic of antiquity, the subject of this notice, and one of the few that Ireland can boast of, has been in course of restoration, under the directions of Mr. Slator, architect. The following particulars, quoted from a correspondent of the *Guardian* will be read with interest:—

"The Cathedral of St. Mary, Limerick, has strong claims upon all who venerate our old solemn ecclesiastical buildings, as well as on the lovers of art and the antiquary. As a specimen of early Gothic architecture, it is of the most perfect in the kingdom. Founded in the year 1172, it was erected upon the site of the palace of O'Brien, King of Munster, who gave up his castle and grounds for the purpose, his descendant, Bishop Donagh O'Brien, subsequently endowing and enlarging it at his own expense. Since the time of its erection the main features of the building have changed but little; and at this day the simple beauty of its proportions, its solid unadorned walls, its massive square piers and lofty roof extending for more than a hundred feet unbroken by line or arch, suggest feelings of calm repose and rude simple majesty, which we seek in vain in the highly-decorated works of a later and more perfect style of art. The peculiarities of its architecture present many features of interest to the antiquary. A square tower crowned with battlements rises to a height of 120 feet, and is stunted in the very centre of the façade directly over the western entrance, being supported inside by three broad pointed arches, springing from massive pillars. These latter are continued up to the nave, supporting arches of the same characrer, while the clerestory windows, which open on a narrow stone gallery, are of the *rounded* style. (?) The basement storey of the tower thus forms the principal entrance into the cathedral. Two narrow aisles into which the various side chapels open, the north and south transepts, and a chancel, complete the interior of the building. It is only within the last few weeks that the true proportions of this interesting and beautiful edifice could be seen or appreciated. The perverted taste of the last century, which erected a wooden screen in the Temple Church and defaced the interior of our noblest cathedrals, sadly disfigured this one also. Most of the arches were filled up with brick or woodwork, one-third of the church was cut off by a huge glazed wooden screen, over which the organ was placed, galleries were erected in the transepts, and all that depraved taste and ignorance could do was done to change and disfigure its original beauty.

"These abominations have now happily been swept away, and there now remains a rough but majestic shell, which to the eyes of the uninitiated, seems almost a ruin. The main roof has been entirely renewed, a handsome east window erected, and the chancel and choir are being properly restored, under the skilful directions of Mr. Slator. The square pews have been everywhere removed, and are being replaced by open benches. The old stalls of Irish black oak, with their quaint and curious carvings, are being now surmounted with appropriate oak canopies, and the greatest exertions are being made to complete the restoration of the entire building in a worthy manner. A large sum of money has been collected in the city and neighbourhood, which is by no means wealthy. Much, however, remains yet to be accomplished before the cathedral can be reopened for service. . . . . Its beautiful peal of bells, carried off some centuries ago from an Italian convent, are well known for the romantic story connected with them; and their sweet musical chimes harmonise well with the memories enshrined in this noble and venerable relic of the past."

The Council of the National Association for the Promotion of Social Science have unanimously accepted the invitation of the Royal Dublin Society to hold their next annual congress in Dublin.

Building societies are now important institutions. It seems from a statement made by Mr. Tidd Pratt that there are now about 2,000 of them in existence, and that their paid-up capital is not less than £8,000,000.

ART CONNOISSEURS.

Under this title the *Architects' and Mechanics' Journal* (New York) has a graphic article, which doubtless numbers of our professional readers will peruse with much pleasure:—

"We some time ago had the honour of a visit from an art connoiseur, *par excellence*, who was in search of a design for a house he was about to build upon a grand and expensive scale. The architects of New York were, of course, quite inadequate to meet such notions as his; so, while in Europe he had got several designs, some in Paris and some in London, in addition to those he had already obtained at home. Was his idea to select one complete design out of this host of suggestions? Oh, no! that would have been sensible and by far too modest. He knew more about beauty than all the New York, London, and Paris architects put together He had selected a portico from this, a cornice from that, a bay window from another, and so forth; then got some very inferior hand to 'draft' him a hodge-podge out of all those varied and incongruous materials, in all sorts of styles, to suit his own ignorant whims. If the reader ever heard of what is called a 'Dutch concert,' in which, at a given signal, a dozen voices strike up a dozen different tunes, varying in solemnity from the 'Old Hundreth' to 'Yankee Doodle,' he will understand us when we say this design was to the eye what such a concert is to the ear. The combination did not quite please him after all; so he came to us to spice it a little for him. We did so by entirely ignoring the whole of the suggestions presented to us, and, while tacitly agreeing with all his absurd notions, artfully contrived to throw them, one by one, to the winds, and worked away as originally as we would under any other circumstances. It was ludicrous to mark the coolness and self-complacency with which this gentleman, as he watched us draw line after line, appropriated to himself every little scintillation of thought as it came fresh from the workshop of our brain. We made breaks, recesses, and projections where none existed; we altered the shape, size, character, and number of the openings; made round things square, and square things round. To avoid monotony, we threw in ornamentation here and cut it out there. 'Very good, indeed!' ejaculated the connoisseur, as each feature revealed itself; 'I'm glad our ideas agree so exactly. I had it just like that, but was induced to change it.' Instead of the great uncouth cornice he had, we designed one entirely different in size and shape. Strange to say, that was the very cornice he had told one of his architects to put. We cut off a long row of useless and costly balustrading to the cornice of his entire building, and gave him a visable overhanging slate roof, as more in keeping with a country house. We thought *that* a rather marked change, at any rate Not at all; that was precisely the roof he had always advocated! In short, when the design was complete, he rubbed his hands in great glee, said it came up exactly to his notion, and went off as proud of *his* performance as if we had been a mere looker-on in the whole transaction, and he the architect. What became of the design we neither know nor care. It was for a locality too distant to affect our reputation or temper by the cruel caricaturing to which we knew it would be subjected in the hands of such an art patron."

THE KILKENNY BROOCH.

Some time since the Rev. James Graves exhibited before the Kilkenny Archæological Society a magnificent ancient Irish fibula of extraordinary size and rare type, which had been discovered in the course of the previous summer; and of which illustrations, drawn and engraved on wood by Mr. Oldham, were displayed in a vol. of the Society's Transactions. The following particulars collected therefrom will be read with interest:—

"It was found, he said, by a labourer in the parish of Killamory, county of Kilkenny, and evidently had not been deposited in connexion with any burial, as it rested, without being enclosed in any cist, or connected with any other remains, on the yellow-clay subsoil beneath the vegetable mould of the field. For size, beauty of ornamentation, and bold, yet elegant design, this brooch was, perhaps, the finest of the rare class to which it belonged. The material was white metal, parcel-gilt on the ornamental portions. It was much tarnished from oxidation. It was irregularly circular, the diameters being 4½ by 5 5-16 inches. The lower or ornamental portion was crescent-shaped and flat, measuring 2½ inches across its broadest part. The annular portion was 7-16ths of an inch in thickness. The flat or lower part was bordered by four monstrous couchant animals, such as are often figured in ancient Irish monuments and sculpture; of these, the two which form the external border had birds' beaks. The fibula was pseudo-penannular, the artist having the type so designated in his mind's eye, but allowing the ends to be connected by two bosses, embraced by the jaws of the monsters just described, and by a band with interlaced ornament, leaving two perforations across the broadest part of the crescent. On each side were two sunk or panelled ornaments, measuring respectively 9-16ths and 10-16ths of an inch square, and set lozenge-wise, from the sides of which the metal was slightly bevelled off in four facets. These depressions were filled up with delicate filigree-work in gold wire, or silver wire heavily gilt. The filigree ornaments consisted of a boss in the centre, surrounded by eight small coiled nobs within a circle of twisted wire, outside of which was also a square of twisted wire, with coiled nobs in the angles. Where the ring joined into the crescent portion of the fibula were two large bosses set with glass, the latter inlaid with white metal. The bosses measured 12-16ths of an inch in diameter, and projected 7-16ths of an inch. On the back the ring of the fibula ended in two monsters' heads in low relief; and on the flattened portion were two irregularly formed rectangular ornaments in low relief, each bearing, within a border ornamented by dots, a monster having a strong resemblance to those which are to be found in such numbers in the illuminations of the 'Book of Kells.' At the base of the crescent was a small but strong loop, probably serving to hold some contrivance to fasten the pin, which was wanting in the security attaching to the pins of penannular brooches. The pin was of very unusual form: it measured 12 inches from head to point; the head was flat and rectangular, the breadth at top 12-16ths of an inch, at bottom 10-16ths of an inch, and the height 1¾ inches. It was attached to the fibula, at the back, by a strong loop. This loop was disengaged at its lower end, seemingly to allow of its being bent back to remove the pin from the fibula at pleasure. In a socket, which was of one piece with the head, and finished with a beaded ornament, was fixed, by two rivets, an acus, 10¼ inches long. Where joined to the head, the acus was ¼th of an inch thick; in the middle it swelled out to a diameter of 5-16ths of an inch, and tapered to a blunt point. The metal of the acus seemed to consist of a core of pewter, covered with white metal. The head of the pin was ornamented by a border, consisting of two monsters, with heads at each extremity. the jaws embracing bosses. At the insertion of the acus was a boss set with glass, the latter inlaid with white metal. In the centre was a sunk panel, with filligree-work, similar to those on the fibula; it was ½ an inch square, and set lozenge-wise, the metal bevelled off in four facets from its sides. The fibula weighed 11 oz. 3 dwts., and the pin 4 oz 9 dwts. troy weight. The acus of the fibula had been broken by the spade of the finder. He should add that on the back of the fibula there was incised an Irish inscription, apparently to the following effect:[*]—Or ar Ochirmac—'A prayer for O'Chirmac.' These characters were inscribed with a pointed tool or graver, and, although partially concealed by oxidation, showed quite clear and sharp when examined by the aid of a magnifying-glass, with the exception of the last three letters, the back of the brooch being there much filed or scratched. Both the character of the letters and the formula of the inscription would be seen to be as old, at all events, as the year 1050, and the occurrence of the legend proved also that the brooch was in the possession of some person *after* the use of hereditary surnames became prevalent in Ireland,—thus establishing the fact that the brooch was *in use* about the middle of the eleventh century. But this was not the most interesting point connected with the legend. Dr. Petrie ('Inquiry into the Origin, &c., of the Round Towers,' pp. 280–82) had proved that the beautiful and highly ornamented doorway of the parish church of Achad-ur or Freshford, in the north of the county of Kilkenny, must have belonged to the period alluded to from the fact of its bearing two ancient inscriptions running round the inner arch, both containing patronymics One of these legends commemorated the names of the chieftain and his wife by whose munificence the sacred structure was erected. Now, it was a most important fact that the same name occurred on the Kilkenny brooch also. MATHGMAIN U CHIARMEIC caused the church to be built, and OCHIRMAC seemed to be the name on the brooch—both identical with the modern form Keerwick, a surname still common amongst the peasantry near Freshford, and also in other parts of the county of Kilkenny under the form of Kirby, and the patronymic of one of the Leinster clans descended from Fergus Luascan, a son of Cathair More, monarch of Ireland in the second century ('Book of Lecan,' fol. 96 *b*). Both the church and the brooch were excellent specimens of Irish art, and Kilkenny might be proud of them. He (Mr. Graves) thought it extremely probable that the workmanship of the latter might be assigned to the same period as the architecture of the church; and he hoped it was not going very far into the realms of conjecture to suppose that this brooch might have secured the mantle of the chieftain, Mahon O'Keerwick, when he stood by and saw Moholmoc O'Cencucain carving the quaint monsters which, as on the brooch, served as ornaments to the western portal of the church. It should not be concealed, however, that the legend on the brooch might have been *graved* on the metal of which it was composed long subsequently to the actual period of the manufacture of the antique; or that it might be intended to commemorate the name, not of the owner, but of the maker. In any case he believed the occurrence of such a record was unique. Mr. Graves stated that he trusted this fibula would ultimately be secured for the Museum of the Royal Irish Academy. The pattern had already been 'registered' for reproduction by a Dublin jeweller, and by his (Mr. Graves's) suggestion had been named the 'Kilkenny Brooch.'"

---

[*] This interesting fact was discovered by Mr. Clibborn, Curator of the Museum of the Royal Irish Academy, whilst examining the antique with a magnifying-glass.

Notes of New Works.

A new dwelling-house is proposed to be built at Ballybrack for the Hon W. C. Dobbs; Messrs. Lanyon and Lynn, architects.

A Wesleyan Methodist Chapel is about to be erected at the village of Blackrock, on the upper road to Kingstown. Style—Transition from decorated to perpendicular Gothic. The builder is Mr. Thomas Creaser, of Drogheda; the architect, Mr. Tarleton. The size is 62 feet by 36 feet, external measurement; 50 feet to apex of gable from ground level.

A new dwelling house, faced externally with cut stone, and to cost over £6,000, is being built for Arthur C. Innes Esq., Newry. Mr. M'Curdy, architect; Mr. Beardwood, contractor.

A new church and convent are to be built at Kenmare. Tenders to 25th inst.

The Ecclesiastical Commissioners have advertised for tenders to repair the church of Lowtherstown, county Fermanagh.

Extensive alterations, &c., have been commenced at the mansion of Harristown, county Kildare, for John LaTouche, Esq. Mr. M'Curdy architect; Mr. Beardwood, builder.

Alterations and additions are about to be made to the gaol at Longford.

The directors of the Bagnalstown and Wexford Railway Company have advertised for tenders to this date for works at Ballywilliam Station.

The new Roman Catholic church of Ballymena was dedicated on the 11th ult.

The new Zion Chapel and schoolhouse at Rathgar, near the high road to Roundtown, are conspicuous objects. At the north-east is a tower, with pyramidal spire in red and blue tiles alternately, and terminated by a weathercock. At the south-west angle is a belfry, capped by a cone of whitish colour.

The works at the Prince of Wales's Hotel are carried out under Mr. Curdy's (not Mr. Nagle's) directions; also those at Messrs. Curry and Shield's, the Royal Insurance Office, and Mr. Donegan's, the eminent watch manufacturer, Dame-street.

The new cathedral church of Ballaghadereen—already described in this journal—was opened and solemnly dedicated on the 11th ult. Messrs. Hadfield and Goldie, architects.

The Commissioners of Bray Commons are about having sundry improvements contracted for, according to plans by Mr. Frith, C.E. Tenders to 1st of January.

The new Roman Catholic church of St. Mary, at Thomastown, being erected from designs by Mr. M'Carthy, architect, is ready for roofing.

The Orphanage recently erected at Glasnevin for the Society of St. Vincent de Paul, after designs by Mr. J. S. Butler, architect, Mr. Meares, builder, has been opened. The building has been already described in this journal.

The Imperial Hotel, Derry, is about to be enlarged, after plans by Mr. M'Curdy, architect. Tenders to 4th inst.

The dedication of the new church of St. Malachi's convent, Dundalk, took place on the 15th ult.

A new wing is being erected to the Royal School, Dungannon, adjoining the Armagh road, which will nearly double the accommodation of that edifice. Mr. M'Curdy, architect; Mr. Wm. Geatens, of Dungannon, the contractor.

Turkish Baths are being erected on Dr. Barter's principle in Sligo, and the first stone has been laid by Miss Jane Lyons, daughter of the mayor.

The new building recently erected in connexion with the convent of Letterkenny, presents an extension façade with tower at west end, and comprises spacious school-rooms, dormitory, cells, chapel, &c. Expenditure about £1,600.

The ground floor windows of Messrs. Kinahan's new front, already noticed, are being fitted up with patent self-coiling shutters, by Messrs. Clark, and Co., of Gate-street, Lincoln's Inn, London. The same firm are also fitting the new mart in Drogheda (Mr. Lyons, architect), and a large establishment in Cork (Mr. Scott, architect), with the same invention.

A new organ, manufactured by Messrs Telford, has been fixed in the Mariners' Church, Kingstown.

Messrs. White and Son, of Dublin, have recently erected an organ in the convent of Westport, and are engaged on another for the cathedral of Galway.

A bronze statue, with drinking fountain combined, is to be erected in Cork, in honour of the late Alderman Fitzgibbon.

The committee of the Limerick Pery and Jubilee Loan Society offer a premium of 5 guineas for the best design for a public fountain.

The new railway bridge at Coleraine has been opened.

It is proposed to construct a railway 12½ miles in length, and forming a junction with the Parsonstown and Roscrea branch of the Great Southern and Western Railway at the Parsonstown Station, to meet the River Shannon half a mile short of the town of Portumna.

We have heard that the tender of Messrs. S. and F. Buxton, of Leeds, for the construction of the Carrickfergus and Larne railway, recently accepted by the directors, was £12,000 below that of well-known contractors in the province.

A new line of railway is proposed to connect the two most important business points of London, viz., the Bank and Charing Cross. The communication will be effected in *five minutes.*

Bray.—Eight dwelling-houses are being built at the end of the Esplanade (which they face), next the harbour; Mr. Joseph Kelly, proprietor, who has also somewhat recently completed, in same neighbourhood, two others, with red brick fronts and cement dressings, after a tasteful design by Mr. Carson, architect. Messrs. Todd and Findlater are respectively building a terrace of eight houses, with one-storey oriel windows and cantilever roofs, on the Strand; Mr. D. C. Ferguson, architect; Mr. Potts, builder. In the town a block of business premises, with dwelling-house, is about being built; Mr. Lyons, architect. Two terraces of important dwelling-houses are in course of erection on Quinsborough-road, on the opposite side to the terrace recently built by Mr. Dargan, after plans by Mr. Wilkinson, architect. Various other works of a domestic character are also in course of completion here, and progress is manifest in all directions. The railing erected along the Esplanade is by Messrs. Morton and Co., of Liverpool, the patentees of various patterns of wire strain fencing. The Earl of Meath's claim to be lord of the manor has been admitted. Portions of the commons have brought at a recent sale prices averaging from £1,000 to £1,500 per acre, and will be laid out in building sites, 125 in number, together with a public park of ten acres in extent, a square of three acres for markets and a fair green. The Commissioners have realized £9,000 by the sales, to be expended, after deducting expenses, in further improvements. What a revolution has been effected here in a few years! and another is sure to follow.

Review.

On the Construction of Horse Railways, &c. By Chas. Burn, C.E. London: John Weale.

We have said so much already through our columns on this subject, that we fear to weary by repetition; we therefore can only glance at the pamphlet before us, which advocates the adoption of this principle of locomotion both for branch railways and street traffic. Amongst many other suggestions, evidently emanating from a practical mind, fully qualified to treat the subject in all its bearings, we find one peculiarly noteworthy, and to this effect:—"That it would be desirable to have the *gauge* of street railways *the same as for locomotive* railways (especially in London), as we deem it not impracticable that goods from one railway terminus could be transported on the trucks during the night through the streets of the city to another, and by that means free the streets, in a great measure, during the day from the cumbersome and unsightly goods vans." If for this purpose alone, the application of horse railways would unquestionably prove a desideratum, but we believe the principle to be capable of much greater extension, and hope soon to see it suitably adapted in our own city, as well as in the provinces.

The statuette model, by Mr. J. H. Foley, R.A., sculptor, after which the Goldsmith statue for Trinity College, Dublin, is to be formed, is now on view at the Museum of the Royal Irish Academy.

Dr W. K. Sullivan commenced a course of lectures on chemistry at the theatre of the Royal Dublin Society on the 12th ult.

The Directors of the City of Dublin Steam Packet Company, in their recently issued report, allude to the fact that although the Lords of the Admiralty arranged three years ago to provide for the accommodation of the service at Holyhead, the works have not *yet* been commenced. In same document the speed of the new steamers is thus estimated:—The Leinster, 20½ statute miles per hour; the Connaught, 22 miles per hour; the Ulster nearly the same, and the Munster somewhat better.

The Northern Architectural Association of Newcastle have passed a resolution recognising the desirability of a general alliance of the institution of architects, in order that combined action might be taken if any question should arise affecting the interests of the profession. The Liverpool Architectural Society will be happy cordially to co-operate in the attainment of the proposed objects.

Miscellaneous.

Report on Patents.—The Commissioners of Patents appointed under the Patent Law Amendment Act, 1852, have just made a report of their proceedings for the year 1859. The number of applications for provisional protection recorded within the year 1859 was 3,000; the number of patents passed thereon was 1,976; number of specifications filed in pursuance thereof was 1,897; the number of applications lapsed or forfeited, the applicants having neglected to proceed for their patents within the six months of provisional protection, was 1,024. The progressive stamp duty of £50 was paid, at the end of the third year, on 604 patents (out of 2,000), and 1,396 became void. The additional progressive stamp duty of £100 was paid at the end of the seventh year on 207 of the 604 patents remaining in force at the end of the third year, and 397 became void. Consequently nearly 70 per cent. of the 2,000 patents became void at the end of the third year, and nearly 90 per cent. became void at the end of the seventh year. All the provisional, complete, and final specifications filed in the office upon the patents granted under the Act since 1852 have been printed and published in continuation, with lithographic drawings accompanying the same. Printed certified copies of the specifications filed in the office, as also certified copies of patents and of the Record Book of assignments of patents and licenses, with copies of such assignments and licenses, have been sent, in continuation, to the office of the Director of Chancery in Edinburgh, and the Enrolment Office of the Court of Chancery, in Dublin, pursuant to the Act of 1852, and the Act of 16 and 17 Vict., c. 115. The work of printing the specifications of patents under the old law, 12,977 in number, and dating from 1711 to 1852, having been completed, short abstracts or abridgments of specifications, grouped under the different heads of invention, are being prepared, and many have been published; for example, abridgments of the specifications of patents relating to the propulsion of vessels, commencing in the year 1618 and ending 1857, nearly 1,000 inventions, have been published in one small volume at the price of 4s. Other series are in the press, and it is intended to publish at the rate of eight or ten series in each year, completing the work in five or six years.—*Mechanics' Magazine.*

Redtapeism.—It is stated by the *Engineer* that "cases have been known of the whole 14 years' duration of a patent having been expended in unproductive correspondence with Government officials, who, however, adopted the invention as soon as the inventor's patent rights expired. Of these, one, in 1847, wrote to the then Secretary of War, who wrote to the Adjutant-General, who wrote to the late Duke of Wellington, who wrote to the Clothing Board, who wrote to the Secretary at War, who wrote back to the inventor, communicating nothing practical as the result of nearly two years' deliberation and procrastination on the part of 'the circumlocution office.'"

The Builder Lord Mayor Elect of London.—Alderman Cubitt is to be Lord Mayor of London for 1861. From 1810, when he commenced his apprenticeship, till 1851, when he retired from business, having amassed a princely fortune, he has been identified with building pursuits in connection with the great house of Cubitt and Co. The alderman was born at Buxton, in Norfolk, in 1791, and served four years in the navy. Though now in his 70th year, he is said to have an active mind and much capacity for business.

Do Railways ever Wear Out?—Mr. Herapath, Editor of the *Railway Journal*, at a meeting of the West Flanders Railway Company, made a remark which will surprise many people. He affirmed, on the authority of one of the ablest railway engineers in England, that rails do not sensibly wear out, unless at the stations and places where there is "skidding." Experiments have been made by taking up rails which have been subjected to the ordinary wear from passing trains, and it has been found that even after 12 months' constant use they have not appreciably diminished in weight. This proves that they could not have been worn sensibly, and the same fact has been demonstrated after rails have been used for a series of years. Near stations, to be sure, where there is much sliding and slipping in consequence of the application of the brakes, there is much wear evident, but this results from slipping friction and not rolling.

Westminster Bridge.—A return made by the First Commissioner of Works shows that since July, 1856, when the report of a committee stated that £50,000 had been expended upon Westminster Bridge and the approaches, there has been a further sum of £196,283 laid out upon the bridge, and £36,919 upon the approaches. The engineer, Mr. Page, reports that he expects to be able in January next to give possession of the piers and abutments of the new bridge to Messrs. Cochrane and Co., who have contracted to complete the iron work of the second half of the bridge in nine months; their work, therefore, according to their contract, will be done by the end of October, 1861. In that case, allowing time for the foot pavement and roadway, the new bridge may be expected to be completed about Christmas, 1861. The width between the parapets will be 84 ft. 3 in.

Architectural Criticism in America.—Describing a jeweller's store recently erected on Broadway, N.Y., a local journal says—"This new establishment may be called 'The Diamond Palace of Broadway,' for if the most consummate elegance, united to elaborate decorative skill, have ever culminated in magnificence and beauty, the store is entitled to that high distinction. It may confidently be said, that up to the present time no more gorgeous or elegant building has been erected on Broadway. Indeed, there are many persons who, having been great travellers and good judges, have not hesitated to say, that this establishment not only excels all its predecessors in this country in solidity, elegance, and in beauty of decoration, but that there is no similar establishment in the old world which can in any way vie with its elaborate and artistic arrangement. Of all the stately structures, magnificent in their white beauty and solid strength, which have leaped into existence on each side of our great thoroughfare at the waving of the Money-King's wand, none has equalled the new diamond and jewellery store above described, and so purely classic; each of its columns is a thing of beauty, with chiselled plinth, abacus, pedestal, capital, and shaft. Passing beneath the dome, and through the great ebony door—lighted by panes of glass, whose like in size and quality New York has never before imported—to the stainless floor of the first storey, you are dazzled at once by a maze of marble counters, glass cases, and mirrors, massive chandeliers in bronze and gold, with glittering pendants; by the gleam, glare, and starshine, which make the scene more like the interior of the Arabic Cave of Lustre than the five-storey trading-place of a modern American firm. Perhaps no building has been erected in our city, since the Custom-house was built of solid granite in every part, which is so well calculated, from the massiveness of its foundations and the thickness of its walls, to resist fire, burglars, and the ravages of time, as the magnificent structure we here describe. And yet, with all the depth of vault, and ponderous inner safes, it is so fairly fashioned without and within, that its great strength and solidity is lost sight of, and the whole effect produced to the eye of the beholder is that of an airy, magical structure, the abode of the sylphs and the gnomes, which may dissolve like the phantasma of a cabilistic mirror when the hair that holds the keystone is snapt in twain."

Antiquity of Stencil.—In the "Philosophical Transactions" for 1838 we read that Procopius, in his "Historiæ Arcana," says the Emperor Justinius, not being able to write his name, had a thin, smooth piece of board, through which were cut holes in the form of the four letters J V S T, which, laid on paper, served to direct the point of his pen; his hand was guided by another. Possibly, this way likewise has given the hint to the first of our cardmakers, who paint their cards in the same manner, by plates of pewter or copper, or only pasteboard, with slits in them in forms of the figures that are to be painted on the cards. Such is the art of stencil, which has been applied, in our time, to decorating the walls of rooms, as well as to the marking of linen.—*Timbs' Curiosities of Science.*

Comparison of Speed.—The ordinary rate of speed, per second is as follows:—Of a man walking, 6 feet; of a good horse in harness, 12 feet; of a good sailing ship, 18 feet; of a reindeer in a sleigh on the ice, 24 feet; of a race horse, 72 feet; of a hare, locomotive, and hurricane, 84 feet; of sound, 1,092 feet; of a cannon ball, 1,344 feet; of the earth's rotation at the equator, 1,521 feet; of the earth's velocity in its orbit, 98,132 feet, or near 19 miles; a ray of light travels 200,000 miles in a second.

TENDERS

For the first portion of the Roman Catholic Church, Birkenhead: E. Welby Pugin, architect, of the firm of Pugin and Ashlin. Quantities supplied by Mr. Marples.—

London Building Company	£4,625
Sherriff	4,471
Farrell and Ledger	4,120
Glaister	3,451
Yates	3,411
Watts	3,383
Waters	3,322

[Note.—The Editor of this journal would feel much obliged by members of the profession adopting the same course as the gentleman above-named, by *sending* lists of tenders for publication.]

Theatre Royal.—Mr. and Mrs. Kean's engagement is a *something* worth recording, but no room is left for *criticism* on their merits. In the higher walks of the drama such perfection is attained by Mr. Kean, that a slight regret *may* be experienced that he would condescend to the inferior melodrama, such as the impersonation of the *Corsican Brothers*, however much he may have peculiarized it with his own identity. Not one whit less refulgent, and with a consummation of gracefulness, tenderness, and energy of passion respectively combined, shone his excellent partner—a lady whose professional attainments have always elicited admiration, and whose personal attributes in private life always commanded respect. What a contrast to the subject of our last notice!—the *classical* and the *ludicrous!*—but comparisons are odious, and we abstain. In theatrical *parlance* we may announce, that for "merry Christmas" novelties—unquestionably more attractive than any preceding year—are in preparation.

Thomas Brawn Manufacturer of

ECCLESIASTICAL AND DOMESTIC MEDIÆVAL METAL WORK,

IN SILVER, BRASS, AND WROUGHT IRON;

Sacred Vessels, Memorial Brasses, Metal Screens, Altar Rails and Gates, Hinges, Handles, &c.

METAL READING DESKS, LECTERNS,

Pulpit Lights, Coronae, Chandeliers, and Standards for Gas and Candles,

SPIRE AND GABLE CROSSES,

And every description of GAS FITTINGS—Candlesticks, Lamps, Branches, and Branch Candlesticks, &c.

T. B. begs to inform the Clergy, Nobility, and Architects in general, that he has been practically engaged for upwards of 14 Years in the Execution and Manufacture of Mediæval Metal Work, from Drawings of the most eminent Architects.

107, BARR-STREET, GREAT HAMPTON-STREET, BIRMINGHAM.

MOORE'S PATENT MOVEABLE GLASS VENTILATORS,

FOR EVERY DESCRIPTION OF PUBLIC AND PRIVATE BUILDINGS, FARM BUILDINGS, HOTHOUSES, CONSERVATORIES, WAREHOUSES, MARKET-HOUSES, SHIPS' CABINS, RAILWAY AND PRIVATE CARRIAGES, BELL TURRETS, ALSO FOR VENTILATING SHAFTS, ETC., ETC. (PERFECT VENTILATION GUARANTEED.)

Patent Self-Shadowed Glass,

FOR CATHEDRAL, CHURCH, AND ALL KINDS OF ORNAMENTAL DECORATION.

PATENT PRESSED GLASS CLOCK DIALS FOR CHURCH AND OTHER CLOCKS,

Transparent in any Colours,

FOR ILLUMINATING BY NIGHT, AND HAVING A SOLID OPAQUE APPEARANCE BY DAY.

All that can be desired is obtained, and the saving of cost in Re-gilding, Scaffolding, &c., is effected, the Dials being permanent. The additional cost depends upon their size and amount of decoration. The Price will bear comparison with the ordinary Clock Dials at present in use.

PATENT TRANSPARENT GLASS LETTERS IN ALL COLOURS, SILVER OR GOLD, Etc., Etc.

MOORE'S PAMPHLET ON "VENTILATION" FREE BY POST FOR TWO STAMPS.

81, FLEET-STREET, LONDON, E.C.

TO BUILDERS, DECORATORS, CONTRACTORS, ETC

Genuine White Lead, best manufactured Zinc Paint. Pure Raw, Boiled, and Refined Linseed Oils. Fine American Turps, Rosin, Pitch, and Stockholm Tar. Ground Paints of all colors, Patent Dryers, Red Lead and Putty. Gold Size, Torch Oil, Coal Tar. Black, Red, Pine, Oak, and Copal Varnishes. Unadulterated Colza, Petroleum, Phenola, Photogen, and all Lamp Oils. Superior Olive, Lard, and Sperm Oils, for engine use. White and colored Cotton Waste. Best Glue, Russian Tallow, Cart Grease. Paints to any color, mixed ready for use, in small and large quantities, to order, well adapted for the country and exportation. Export orders promptly executed, with goods of *best quality*.

GEORGE SPILL, OIL AND COLOR MERCHANT,

65, 66, & 67, ST. GEORGE'S STREET, LONDON DOCKS.

W. WARNE AND CO.

CALL the attention of Engineers and others to their PATENT MINERALIZED and VULCANIZED INDIA-RUBBER, in Sheets, and for Valves, Washers, Railway Buffers, Bearing Springs; Hose Pipes (delivery and suction), Flexible Tubings, Driving Belts, and to their improved Anglo-American FLEXIBLE CANVAS and INDIA-RUBBER PACKING, for Steam Joints and Piston Rods.

SOLE MANUFACTURERS OF THE
NEW PATENT MINERALIZED KAMPTULICON,
AND OF THE
MINERALIZED INDIA-RUBBER SOUNDLESS CARPET CLOTH,

Combining Extreme Flexibility, and consequent non-liability to cracking; Durability and Impermeability to Wet; warmth to the feet and softness to the tread.

SOLE MANUFACTURERS OF
WARNE'S NEW PATENT INDIA-RUBBER MATS.

These Mats consist of Tubes of India-Rubber, of various configurations, placed vertically in contact with each other, and are far more efficient than any other description of Mat. No ordinary wear can sensibly affect them; they thoroughly clean the feet like a brush, and the dirt removed falling through the cells formed by the tubes, is not carried by the feet on to the floors and passages, which are consequently kept perfectly clean; and by removing the Mat, the accumulated dirt is easily swept away. They are also made with backs.

The Mats never clog, require no beating, and are readily cleansed by water. Unlike all other Mats, water in no way injures them, and it neither lodges on or is absorbed by them. Indestructible by damp or wet, these Mats, made to any shape, size, or thickness, are especially suitable for uncovered passages and out-of-door purposes.

The invention is peculiarly applicable for Mats for Baths, Conservatories, Laundries, Sculleries, Ships, Steamers, Omnibusses, Carriages, and Seats, also for Churches, &c.; and for Scrubbing Brushes for Decks, and Wooden and Stone Floors, and for Housemaids' Mats.

All Mats are marked W. WARNE and CO., Patentees, London. Orders received at the London Warehouse, 9, GRESHAM-STREET WEST, E.C.; or at the Factory, TOTTENHAM, N, MIDDLESEX.

The Dublin Builder.

VOL. III.—No. 25.

INDEFINITE SPECIFICATIONS—DONALDSON'S BOOK.

IT is no unreasonable assumption that two-thirds the disputes—and they are legion—that arise between builders and their employers, are directly traceable to the provisions and wording of specifications—where they at all exist—in connection with building works. Some would-be economists, who ignore the architect's capacity, and have full confidence in their own cleverness and the builder's integrity, are quite content to commence operations without a specification, and with a simple agreement, embodying nothing—frequently without either—and affording an excellent opportunity for enjoying to all intents and purposes that questionably prudent hobby, as the sequel—"a trial at law"—usually proclaims. On this class, however, it is outside our present purpose to dilate *in extenso*, and therefore we confine ourselves to the simple consideration of the character of those documents furnished by architects, descriptive of the various materials, scantlings of timber, the several qualities of artificer's work, and the numerous other provisos relative to an intended contract work. In a former number of this journal, and under the title of "Undefined Foundations, Architect Umpires, Party Walls, and Uniform Measurement," we enumerated some of the inconsistencies which frequently present themselves in specifications, and owing to which, and the uncertainty of "law," either the proprietor or the builder is invariably victimized. To these we need not again refer. The honest tradesman is better disposed to enter on his work with a *stringent* specification to guide him in his calculations and duties than a *lame* one, which he foresees will at winding up cause much trouble to both proprietor, architect, and builder, and involve a large additional outlay for extras before the work can be completed conformably with the apparent intentions of the architect. However, it is clearly a builder's policy *not* to interfere with an architect or his *intentions*: he has to deal only with the documents before him, and suggestions or interference would more probably provoke a rebuff than be received graciously.

Architects as a class invariably, and very properly, desire to maintain supremacy from first to last in their associations with a building work, and no reasonable member of the fraternity will find fault with a builder for adhering to the letter of his engagement. To the client, however, an incomplete specification may prove disastrous, as he finds himself hurried *de necessitate* into an additional outlay on which he did not calculate; and, moreover, was led to regard as an impossibility, from the presence of that protecting clause, that "no extra work will be paid for unless ordered by the proprietor or his architect." But he, too late, finds himself in the happy (?) position that the architect, seeing the *necessity* of various additional works, had exercised his professional prerogative, and ordered them to be executed. The builder refers to his contract drawings and specifications, which he proves to the proprietor do not contain any provision for *a single item* included in the "extra little bill;" moreover he has the architect's authority, which is empowered to be given by the quoted clause in the specification, and delicately suggests the *desirability* of "an amicable settlement." Whether the pleasant and prudent alternative of making "a virtue of necessity," or the unpleasant one of confiding the settlement to "his attorney," is to be subsequently adopted, the discrimination of the proprietor can alone determine. Our readers connected in any manner with the building profession must at once admit the fidelity of the picture—"a plain unvarnished tale"; and numerous members of that extensive community called the Public will, from their *experience in such matters of art*, add an approving sentiment. We need scarcely cite special examples of the various litigations which periodically occupy the time of gentlemen of the long robe, and excite much interest amongst those inside our pale; the principle as regards *each* is equivalent, and the foregoing remarks equally applicable. With the double view of enlightening those who embark in building works as to the consequences of defective specifications, and of placing in a position, for the reference and guidance both of the profession and the junior aspirants, examples of trusty documents used in various important works, and again of suggesting a general form—a skeleton reminder—embracing the heads of the various departments of work, and capable of adaptation to *any* class of building, the Professor who so ably and worthily presides over the architectural class at the London University has produced a book in two volumes. Donaldson's specifications have lain admittedly too long before us unnoticed, and doubtless with the contents and characteristics of the book the majority of our professionals are by this time familiar, and have derived advantage therefrom. The Professor prefaces as follows: "The construction of a specification is *very simple.* It will generally be found that a great portion of the same particulars exist in all contracts, unless modified by some special local circumstance, or influenced by some peculiarity as to the class and destination of the edifice." It then enumerates the constituent parts of a contract, viz.:—"1st, the legal obligations; 2nd, the drawings; 3rd, the specification." And amongst other matters premises "*that any damage to the adjoining premises is a usual contingency to be provided against.*" "Consequently these items *need not appear* in the *body* of the *specification;* and as they refer to all the trades, prevents its being encumbered by useless repetitions." Again, another paragraph attracts particular attention, and refers to the drawings and specification, viz.:—"The architect should have two sets—the one, signed and forming part of the contract and numbered, to remain in his office; the other—which may be tracings—to be on the building, in the possession of the clerk of works, and *accessible* to the contractor for verification from time to time." "Moreover that *he* is *entitled to require by the contract that the builder should make at his own cost the copy which he will want for his own use.*" Referring to architects to public boards, the Professor suggests "that an architect cannot be *too elaborate* or *cautious* when having to do with a stranger or person of doubtful reputation, as sometimes happens in the case of *open competition* for public bodies. These boards are less cautious as to the character of the contractor, than anxious to secure the *lowest amount*, trusting to remedy any defect by the stringency of the contract and *elaboration* of the specification,—forgetful even, that with these precautions a wide door is still left open for *fraud* and *bad work* by *unscrupulous* men." The Professor tells some home and well-timed truths in the above remarks, and which all more or less bear on our subject; but we must certainly take exception, considering the practice in Ireland, to the right of an architect *charging a contractor* for a *working copy* of the plans and specification. A wide door is indeed *here* left open for fraud and *sub rosa* understandings, for which, once money transactions commence between architect and builder, peculiar facilities are palpably offered. The right to repair damage to adjoining premises is regarded by the Professor as such a *legally admitted fact*, independent of any special provision in the specification, that we must express a wish it had been previously established *here*—or that it even were so now—and a vast amount of trouble and expense in litigation might have been saved. Amongst the numerous specifications included in this work, the only one having reference to Ireland is that of the Omagh Lunatic Asylum, for which the late William Farrell was architect; the quantities as measured by Messrs. Thomas Turner and Patrick Kerr respectively are also given. The very voluminous specifications of the Houses of Parliament and New Royal Exchange, together with numerous others of architectural and engineering structures of various characters and styles, erected after plans by Barry, Angell, Scott, Bunning, Ferry, Tite, Wyatt, &c., architects; and Stephenson, Page, Brydone, Simpson, &c., C.E's., are comprised in these works, altogether presenting a compilation of most valuable documents, with, in some instances, an accompanying illustration.

In publishing this valuable work the author selected an old and highly respectable firm—Messrs. Atchley and Co.—enjoying an extensive influence amongst the profession at home and abroad, and which is "half the battle" in the victory of any such undertaking, however famed and popular the author.

THE POLITICS OF ART.

INASMUCH as art is peaceful, and is nourished in the bosom of happy prosperity—a symbol of dignified and thoughtful repose—it seems grateful to turn to it in these days of political commotions and troubles, to find consolation in its serenity, and instruction in its deliberate eloquence.

We build galleries, and bring together in them the choicest fruits of that Tree of Life, the human soul. We gather exotics from the old world, the works of old masters and new, of ancient Italian schools and modern French and Flemish. We cull choice bits of poetic truth from domestic studios, and hang them up to ripen in the public heart, and fructify there in gentler manners, purer habits of life, and more refined and elevated ideas of our relations with the handiwork of the First Artist. It is good for us to get away from the bustle of the streets and the noisy dangerous rumours of the world, and enter these quiet academies of art. Their stillness is the fountain of intellectual peace, the source of the profoundest harmonies.

This is the political economy of art. Its "service is perfect freedom," under the protection of the laws of divine unity; and every man is instinctively open to impulses from it of good or evil tendencies, according as the artistic expression in picture, statue or building is good or bad. It is impossible to estimate the amount of moral influence such things have over our conduct; but that it is very appreciable is evident from the fact that every excellent human work, whatever that work may be, is excellent both in a subjective and an objective sense.

"It blesseth him that gives and him that takes.
'Tis mightiest in the mighty."

It is quite unreasonable to suppose that the Creator has implanted for nothing in the human soul the almost divine power of conceiving a beautiful idea through any of the avenues of intelligence, and in any way expressing it, whether by words or things or acts. Every man is an instructor for his fellow-men in proportion to his capacity for such conception and such expression. Thus the laws of moral reciprocity are constantly at work. And if we hold a man to be a benefactor to his kind who originates and carries into execution any work which has for its object the improvement of his fellows—as Garibaldi, or the signers of the Declaration of Independence, or Howard, or Watt, or Fulton—we should regard with no less respect those, the depths of whose humanity are disturbed by an equal "joy of elevated thoughts," even though the outward expressions of these thoughts cannot be measured in their excellence by any definite and practical attainments of enlarged political liberties and improved mechanical science. The conception of Shakspeare or Michael Angelo is at least as godlike as that of Watt or Washington, and the resulting poetry or art on the one hand is of as much value to the well-being of mankind as the resulting steam-engine or political liberty is on the other. If the springs of action lie equally deep in the powers of the human mind, the results, whether considered practical or theoretical, are equally blessed.

Therefore art is as necessary to the solving of the great problem of human destiny as politics. It is in fact itself a great, though usually unrecognised, political agent, acting indeed not directly to diminish our taxes, or extend our franchise, to improve and defend our liberties; but going behind and beyond these things, civilizing, expanding, refining the human mind to the better appreciation of true freedom, and to the more profound insight into its nature and necessities.

But it is not for every one to retire to the stillness and sanctity of galleries of art to learn this great lesson of civilization. It is not every one who can do this, and many would not if they could. Such persons, however, do not avoid the subtle influences of art; rather are they more sensitive to them, because these influences come unawares in their daily walks, intruding into vacant spaces of thought, ever working unseen and unsuspected. If art possesses any element of political or moral power, architecture is certainly its most potent and democratic agent in these respects. A man enters a gallery of art forewarned and forearmed. He involuntarily encases himself in an armour of criticism, and thus too often becomes obstinately invulnerable to the fine attacks and stratagems of the artist. Every educated man is expected to be a good critic of a picture, and he feels the necessity of bearing out his education, and indulging in more or less of the slang of the studio, signifying nothing. But the learned and the unlearned walk the same pavement in Broadway. The lawyer, the merchant, the clerk and the mechanic proceed to their business down town and return to their homes in the evening, quite unsuspecting that they have been unguardedly sowing in their breasts the seeds of good or evil with every glance at buildings on the right or left.

If our readers think we have made a rash statement, we beg them to follow us kindly a little further.

The poet Keats said:

"A thing of beauty is a joy for ever,"

meaning that its very beauty renders it immortal in the work of felicitating and comforting the human heart. A good poem never dies. It passes from lip to lip, from heart to heart, on a mission of peculiar grace, appealing to each man's individuality, and opening to him a new vision of delight, or surprising him with the apotheosis and glory of an old and familiar thought. Its beauty is its life. So with a statue or picture. If indifferent in sentiment or execution, it encumbers the earth—is neglected and forgotten. If inspired with a beautiful idea, it is never idle. There is some part of every human being to which it may appeal with peculiar emphasis. It forms part of the joy of his existence. It becomes incorporated with his being, and if it is ever forgotten in its actuality, it is ever present in its essence, ever re-occurring in that indefinite feeling of content and gratitude which makes every intellectual being competent to appreciate and more or less desirous of attaining to some future state of utter beatitude. A work of art is, in fact, the love of God, which, in some especial form, has entered into the heart of a man, and has been humanized and materially expressed by him, so that we, his fellow-creatures by human sympathy, may be made to understand some part of divine Providence which otherwise we would have suffered to pass unnoticed and without its peculiar blessing. It seems to us that this does not admit of a doubt. And the converse of the proposition is true likewise. A work of error and bad taste is in some degree an evil for ever. It constantly corrupts, as a "thing of beauty" constantly elevates.

Art is a republic, as literature is. Its basis is Integrity, and its strength is Union. If the laws of its beautiful unity are broken, and it is divided against itself, it falls. From this republic of art there may be secession as disastrous as that from a republic of states. No panic ensues indeed, and Wall-street is undisturbed; but the stocks of public taste depreciate, the avenues of civilization are encumbered with rubbish, healthy credit, which nourishes true merit, is lost, and at the base of public morality, so far down that we do not suspect it, a subtle influence is set to work undermining and weakening, and when the fall takes place we wonder what caused it.

True architecture is not merely the strict observance of certain fixed academical rules of proportion, but it is founded upon laws of much larger application—those of truth and beauty. An architectural offence therefore is not, as is often supposed, a mere rebellion against certain conventional rules only appreciable by architects. Every man in viewing a work of architecture, if he brought to bear on it the judgment of common-sense (which, strangely enough, he rarely does), would arrive at a just valuation of its merits or demerits. As it is, here in New York public favor instinctively tends towards expense. The more costly an edifice is the better. Admiration is in proportion to the dollars spent upon it. This may be mercantile, but it is very foolish and very dangerous. We appeal from this tendency to the sober good sense of the people. Stones, hammered and carved elaborately in the rash license of treason against art, have no longer sermons in them for our good. The mason may pile them up very skillfully in our sight, but there is no health in them. They are lies. And an elaborately builded lie set up in the streets is a continual shame to those who countenance it, and a debauching influence in the eyes of the public. Judging instinctively as they do, and as we fear they always will, they create them standards of taste; and to build well according to such standards is impossible. To build well, in fact, under such circumstances, is to throw pearls before swine.

A picture which is untrue to nature and degraded in treatment may be turned with its face to the wall, may be removed as something contaminating and unhealthy. But a bad work of architecture looks a century in the eye, and the people cannot but stare back at it.

"Till, seen too oft, familiar with its face,
They first endure, then pity, then embrace."

—*New York Architects' and Mechanics' Journal.*

Our contemporary the *Agricultural Review* pronounces the establishment of Messrs. Austin, in Westmoreland-street, to have been "recently rebuilt in a style not to be surpassed by any similar establishment in London."

The engineers and firemen employed on lines in the neighbourhood of Newcastle-on-Tyne have commenced a movement for reducing the hours of labour.

New barracks, said to be handsome, lofty, and commodious, but with too much light, causing a glare and excessive heat, and on a low site frequently under water, have been built at Bareilly in Bengal. General Wyndham stated that no barracks should be built in Indin except with logs covered with canvas.

Notwithstanding the increased facilities presented by the establishment of district post-offices in London, it has become necessary to enlarge considerably the accommodation at St. Martin-le-Grand, by adding to the mail office and excavating the entire enclosure from the portico to the end on the south side, and to the kerbstone on the west, underneath the present railings. The pneumatic tube principle is also likely to come extensively into vogue. Talk of the Hills' cheeseparing! but who but Rowland Hill, the originator of the penny postage—the grandest and most successful financial scheme ever conceived—has caused this most comprehensive development of public requirements under a liberal *régime*.

FINE AND ORNAMENTAL ART EXHIBITION OF 1861.

ACCORDING to present announcement, the first day of May, 1861, is fixed for the opening of an exhibition in this city in connection with the Royal Dublin Society, and numerous influential noblemen, gentlemen, and devoted votaries of art comprise the committee. In a previous number of this journal, however, and when the project was first being matured to a tangible shape, we expressed our conviction that the space intended to be devoted to the exhibition was far too limited, and from this we have had no reason since to deviate. Our objection may be met with the statement, that the old triennial exhibitions of the same society on the same premises, but when the accommodation and space were considerably less, were notwithstanding eminently successful—and if so, why should not this be proportionately so? In answer, we must remind those who would fain establish *that* as a reasonable argument, that once the palate has been feasted on *dainties* it will not afterwards be easily reconciled to the *coarser fare* which it previously relished; and so it is in this project, after the eyes of the very identical public who are expected to be its supporters have been dazzled with the beauties of the exhibitions of 1851 and 1853 respectively, we anticipate—we trust erroneously—that they will view with considerable apathy this comparatively paltry display. We desire not to throw cold water either on the intentions or the energies of the committee, but to advance in good time a simple suggestion. The erection of a gallery in the Agricultural Hall is at best a mere makeshift; the building is quite *too low* without making it *lower*, as this inevitably will, both in effect and reality. It answers its present purpose sufficiently well, but is not suited for the contemplated change, which we predict will abortionise it. However, with remonstrance our mission ends, and we leave the result to be judged by the public; but must remark, that it would have been more judicious to have postponed the exhibition altogether, until the National Gallery and its connecting arcade should have been completed, and the museum fully furnished, so as to form accessories thereto. That it will be highly prized by the *beaux* and *belles* of this metropolis as a fashionable lounge we have not the slightest doubt, but that the excellence of its character will attract crowds of provincial and cross-channel visitors, or moreover that the inducements offered to eminent English and Scotch manufacturers, &c., will prove sufficient to their incurring expense in forwarding contributions to the extent to be desired, and indispensable for a creditable display, we certainly *do* question. The guarantee fund, originally fixed at £5,000, has it appears increased to £9,000, and this latter sum will, it is thought, after paying all preliminary expenses, be sufficient to provide against a deficiency in the receipts. We trust, for the credit of the city, and for the satisfaction of the promoters—whatever our own private convictions may be—that instead of a deficiency, there will be a surplus when the balance comes to be struck. However, *nous verrons!*

THE ARCHITECTURAL ASSOCIATION OF LONDON.

ON the 22nd ult. an ordinary meeting was held, Mr. Blashill in the chair, when after some preliminary business Mr. Blashfield, M.A., V.P., read a paper on "the arrangement of churches," of which the following is the substance:—

What I propose to consider is—

First, the influence which our ritual, as it at present exists, ought to have on the architectural features and character of our churches, and whether we are in the habit of paying sufficient attention to this point.

Secondly, the customs, wants, and requirements of modern congregations as compared to those in former ages of the church.

The first reformed English liturgy was produced in 1549, and was followed in 1552 by a second, which is nearly identical with our present Book of Common Prayer. Since that time it has undergone several authorised examinations, and some few changes of importance have been made in consequence, but in all essential points it continues the same.

When we hear a new church discussed, the points usually touched upon are the accommodation, the cost, and the quality of the design. We hear, perhaps, that sittings are provided for 800 or 1,000 persons, and that it cost so much—very cheap or very expensive as the case may be. Then we hear the particular style adopted, the height and treatment of the roof, the richness of the decoration, and the originality, if there be any, of some part of the design, with numerous other details; but we seldom (I think I may say never) hear a church commended because the building itself, independently of its furniture, gives expression to every part and detail of our services. I do not mean broadly to assert that none of our modern churches do give such expression (though as a rule they certainly do not), but I mean to say that when such an exceptional church is met with, people do not appear really to know why they like it; they think it original and clever, but they cannot exactly say why it interests and satisfies them more than larger and costlier buildings, or why, without any copyism, the architect seems to have succeeded in catching the true spirit of mediæval architecture. Now, I think that, unless we discover the element of his success and recognise it as a principle not lightly to be infringed, we shall not make much progress in church building beyond the point to which the revival has already carried us. I suppose we have all felt, in comparing old and new churches, that there is often a deep sense of interest and continued satisfaction in exploring an old church, although it may be very plain and simple, which is totally wanting when we visit a neighbouring modern church, apparently its superior in all the usual architectural features. This is generally attributed to the charm of antiquity and the sentiment of association, and these feelings, no doubt, have their due weight. But there is something beyond this, which I believe to be the existence in the old building of a principle, apparently quite instinctive in the mediæval architect, which is too often—I cannot but think—overlooked by us. The principle I allude to may sound absurdly trite and hackneyed, but it cannot be too often repeated until it is better attended to—it is simply, *that a building should exactly express its purpose*, or, in other words, in the case of a church, that the bare walls, or actual skeleton, before a bit of furniture is introduced into it, should bear the distinct impress of every part of the ritual existing at the time of its erection, and should give expression to all ceremonies and forms of worship about to be celebrated in it. Thus it may well be regretted, in a purely architectural point of view, that we are forbidden to erect stone altars; they were removed in 1550 to make room for communion-tables; and though we may deplore, we can scarcely wonder at the measure.

The Font.—Although the orthodox, traditional, and symbolical position of the font near the western entrance is now very generally adhered to, I have heard a great many different opinions amongst the clergy as to its convenience. Amongst others, Mr. Pettit remarks, "Where the font is suffered to retain its original position, it is generally found near the western entrance, and this, without doubt, is the most appropriate spot for a ceremony denoting admission into the church; yet there may often exist sufficient reasons for placing it elsewhere. And it is of far more importance that we regard, both in position and design and the actual size of the font, the great solemnity of the rite which is administered in it, than that we restrict its locality to any particular part of the building." Wherever it is placed its position should at any rate be well defined and expressed by some modification or exceptional feature in the architecture, so that there may be a perpetual and ineffaceable protest against any future removal by a reforming churchwarden or a new incumbent.

There are, of course, numerous examples in churches built of late years in which the font is given its proper importance, and has a well-defined and yet prominent and open position given to it. An arrangement of the kind has been admirably managed in a small church in Suffolk, lately built by Mr. Scott, where a round tower (after the fashion of the peculiar round towers of that county) is placed at the west end. It is vaulted with stone internally, and forms an appropriate baptistery. But, having noticed the principle, I will not take up time by multiplying examples.

The Reading-desk and Pulpit.—Now, although these two play, if not the most important, certainly the largest part in our services, it is not often that we find one or the other treated as one of the building, or influencing its constructive details in any way. They are usually pieces of furniture which give no more impress of character to the building than the seats of the congregation. The exact position of each, and even the design, are generally not settled until the church is nearly completed; perhaps, indeed, it is fortunate sometimes in the case of the pulpit, as instances might be found where, through inattention to acoustic requirements in the first instance, a change in its position is absolutely necessary. But supposing that the pulpit is of stone and the reading-desk on a stone plinth, this is not all that is required to meet the principles we started with, unless they form part of the building. You may have stone furniture as independent of it as wooden furniture; and, with regard to the reading-desk, architects unfortunately find a great difference of opinion among the clergy: one wants a large desk looking north and west; another wishes the whole desk to face west, and a third wishes, perhaps, to read prayers from a small desk in the chancel seats, and the lessons from a moveable lectern. We have before us the well-known examples of the arrangement of the early Christian basilica, where we find this principle carried out in every point as completely as could be done in adopting a building originally designed for secular purposes to the requirements of public worship; such parts of the building as could be still used in Christian worship were adapted and what was wanting was added architecturally and incorporated in the building as far as possible. Thus the bishop and presbyters, as you know, took the places of the prætor and his assessors, the Roman altar became the Christian holy table, and a choir was thrown out into the nave, enclosed on three sides by low walls. The ambos, from which the Gospel and Epistle were read, were actually built into these enclosing walls, and thus made part of the church. The church of San Clemente, at Rome, as you all know, shows in the most perfect manner the arrangement of the early basilica. Although rebuilt in 790, it was exactly on the original plan, and it is owing to the fact of all the ritualistic arrangements being absolutely solid and architectural, and not merely moveable furniture, that we are able at this time to understand fully the allusions and descriptions of early writers.

As to the pulpit, I will just read a short extract from Viollet le Duc's "Dictionary" on this point. He says:—"In France none of our ancient churches have, as far as we know, preserved any pulpits of an earlier date than the fifteeenth century. It was customary, from the commencement of the twelfth century, in our northern churches to arrange a rood-loft at the entrance of the choir, from the top of which the Epistle and Gospel were read, and exhortations addressed to the faithful when occasion served. In every case these sermons, before the institution of preaching friars, only took place occasionally. The pulpit was then only a wooden stage, closed on three sides, and covered in front with a hanging. But in the thirteenth century preaching became a necessity, which the architectural arrangements of religious edifices were compelled to obey. Exactly to fulfil these conditions the Dominicans and the Jacobins, amongst others, built churches with two naves, one being reserved for the monks and divine service, and the other for preaching; then the pulpits became fixed and entered into the construction. They formed, as it were, a balcony projecting into the interior of the church, carried on corbelling, accompanied by a niche taken out of the wall, and generally lit by little windows. Access was gained by a little staircase contrived in the thickness of the wall." Thus we see the thirteenth century architect at once felt instinctively that when a sermon became a thing of fixed and regular recurrence, instead of an occasional address, he must express the fact in his building. It was no longer sufficient to provide a little moveable stage closed on three sides, but he must contrive a balcony, or some architectural feature, that should distinctly proclaim its original use as long as the building should stand. There is an instance of such a pulpit in the south nave of the Jacobin convent at Toulouse.

The example of ancient pulpits treated in this thoroughly common-sense manner are very numerous, but we must not confine our search after the earliest and best examples to the interior of churches: we shall find some of the best in the refectories of monasteries, used for reading to the monks during their meals.

There is still another part of our services which requires notice, and that is the musical portion. The only point about it which I wish to enforce in this division of the subject is this. As an organ is now almost an invariable appendage to a church, and is generally considered necessary to the proper and decent celebration of our service, it should impart a distinctive character to that part of the building which is destined to receive it. I am aware that this is frequently attended to in modern churches, and always I think with a satisfactory effect; I could name instances of churches where such an arrangement has always appeared to me to give the chief interest and charm to the building. In small village churches where an harmonium takes the place of an organ, a recess in the thickness of the wall may be contrived with very good effect at a small cost, and with unmistakeabie fitness of purpose.

Beyond the absolutely essential division of nave and chancel, I do not wish to occupy your time by saying much about conveniences of plan. This is a question which must depend so much upon peculiarities of site and the number of the congregation, as well as other points, that it would form a long paper in itself. Those eccentric varieties in the form of theatres and lecture-halls I need only allude to, as I hope we are all agreed that turning a church into a great auditorium is not only subversive of all proper ritual expression in arrangement, but renders it almost impossible to conduct the service in a decent and reverent manner.

Galleries.—We all know the numberless objections to these, and I suppose no one would employ them by choice, but where they become actually a necessity, which is often the case, they should certainly be located as part of the construction, and their presence should be expressed externally. Great care should of course be taken as to their height and the steppings of the seats, so that they may neither overpower the church by being too high, nor oppress the occupants of the aisles by being too low. A flat ceiling under the galleries will be found to be much better for acoustic purposes, and more satisfactory to the eye than an inclined one. There is one position, however, for a gallery which is, in some churches, almost unobjectionable from its answering two good purposes—one, that of breaking up and dissipating the sounds from the east end, and preventing echo; the other, that of clothing the conspicuous bareness of the west wall, which, in many churches, is far from agreeable.

Let us take a modern congregation of say 1,000 persons, and consider the wants and requirements we have to meet. The first thing to be noticed is that according to received notions, the seats must be fixed; and if we may judge from the serious inconveniences which attend the use of chairs where they have been tried, they are not likely to come into general use, except as a temporary expedient. The next requirement is, that all the congregation should have an uninterrupted view and hearing of the officiating minister. It may not seem at first evident that an uninterrupted view is necessary, but in point of fact nothing is so difficult or irksome as to keep up one's attention to a speaker who is unseen. This applies, of course, chiefly to preaching.

The next requirement is, that no one should feel too cold or too hot, and that there should be no draughts in the church. If the age demands warming and ventilation, we must give it them. This is a most important point, and nothing disgusts a congregation so much as finding themselves in a cold, draughty, or ill-ventilated church, where the ladies cough all the winter and faint all the summer. I wish to point out that we, perhaps, oftener than necessary, increase our difficulties, and impair the perfectness of the system adopted, by thinking it right to hide away as much as possible all the paraphernalia of chimneys, &c. For instance, I want a chimney for a vestry and one for the warming apparatus; but I am afraid of making a good stack and carrying them to a proper height, lest any one should tell me I have given my church too domestic a character. Ought I not rather to consider that when we insist on introducing domestic comforts into our churches, that fact must, under an intelligent architect, come out distinctly in the character of the building? Our congregations cannot be provided properly and truthfully with the comforts and luxuries of home without paying for it by the disfigurement—if it be a disfigurement—of their churches by domestic features.

Acoustics.—In making observations on the acoustic qualities of churches, it is not sufficient to go yourself once and try how you can hear at any particular part, as there may be many disturbing causes acting at different times; one of the best tests is, whether it is what the clergy call an easy church. Inquire of a few clergymen who have done duty there what they think of it in this respect, and you will form a truer estimate of its qualities than if you ask half the congregation. I believe it is little known how many clergymen's health is seriously impaired by having to do duty, day after day, in a difficult church. It therefore becomes, not only a question of convenience to the congregation, but of health and comfort, in many cases, to the clergyman.

It now only remains for me to touch upon our requirements as to the *musical arrangements* of a church—and here let me say that though it can scarcely perhaps be expected of a church architect that he should be a musician, yet he should make it his business to understand something of the construction of the instruments used in a church. An organ, the most beautiful of instruments when in tune, is one of the most disagreeable when neglected, and every one should know how sensitive it is to damp and draughts, in order to guard against this in his arrangements for the reception of the instrument. If there is a choir, the organ should be placed close to them, and the proper place for it is either in a side aisle of the chancel or in an organ-chamber built expressly for it, which is better. The effect of the instrument will be much enhanced and it will be kept in better tune if the walls are lined with boarding or battens, and if not in a gallery, it should always be raised on a platform some feet from the floor. The worst place for the organ on every account is in the west gallery, if there is one, and I believe organs are never now placed there in new churches. Of course, I don't contemplate the possibility in these days of an organ appearing over the altar. In small village churches, where an organ can seldom be tuned, I think myself that an harmonium is much preferable; it has the advantage of not getting out of tune, and though it has always something more or less wanting in tone, as compared to an organ, it is quite sufficient to lead the singers.

I feel that I have omitted much that might well and appropriately have been brought to bear on the subject, both from haste in preparing this paper and from a wish to be as short as possible; and I now relinquish the subject in the hope that the discussion will be taken up by some of our friends assembled here to-night.

I had intended to illustrate my remarks with diagrams and sketches which might have added interest to a dry paper; but the time was really so short that I found it impossible.

DOMESTIC ARCHITECTURE IN KERRY.

THE following particulars of a recently-erected mansion in this county are given in the local *Evening Post*, and in quoting same the *Cork Constitution* remarks that—

"Architecture seems so much neglected in this country—either there is so little taste for it, so little appreciation of its capabilities, or so little inclination on the part of men of wealth to expend the money necessary to turn them to account—that when we find a proprietor availing himself of them for his own comfort and the ornamentation of his demesne, it may be useful to some of our *building* readers to present them with examples of what may be done under judicious outlay and direction. One example we have great pleasure in presenting, as it is altogether of Cork design and of Cork execution, both architect and builder belonging to this city. The description, slightly abridged, we subjoin:—

'OAKPARK HOUSE.

'The new mansion house lately completed in Oakpark for Mr. Maurice F. Sandes deserves a word of passing notice at this moment. This house has been built by Mr. R. Evans, builder, from the designs and under the superintendence of William Atkins, Esq., architect, Cork, and is now, we believe, the most elegant and most comfortable residence among those of our country gentry—whether we take into account the beauty of its architectural design and the correctness of its execution, its internal adaptation and appliances for the comfort of its inmates, and the taste and richness of its interior decorations. The house stands on a gentle eminence in the demesne, now greatly enlarged, sloping to the south, and commanding a fine view of the western side of the Tralee and Dingle mountains, extending from Brandon Head, dipping precipitately into the sea, some twenty-five miles, until the chain sinks into lowland to the eastward of Slievemish.

'The entrance is under an open carriage porch, communicating with an inner one leading to the hall, and through an octagon conservatory, into the drawing-room. The hall is 30 by 20 ft., opening into the staircase, 30 by 19 feet, by an arcade resting on polished marble shafts, with Caen stone, carved capitals and bases; from these apartments open the principal rooms, *en suite*, all having a southern aspect. A large conservatory terminates the eastern end, to the rere of which is the library and study. The kitchen and minor apartments occupy a wing running north.

'The first floor contains spacious bed-rooms and dressing-rooms approached from an arched gallery, terminating the principal stairs, as well as a corridor leading from the back stairs. The rooms throughout are lofty and admirably lighted, those of the lower floor being 15 feet high.

'The style of architecture employed is an adaptation of the Gothic of Northern Italy to the usages and refinements of modern society. Mullions have been altogether avoided in the windows, the sashes slide in the usual manner, each being glazed with one sheet of plate glass, affording an uninterrupted view of the surrounding scenery. In the hall and two principal rooms are large bay windows, adding greatly to their size as well as appearance. The ceilings throughout are of timber, the designs varying in each room. The principal timbers are borne by carved Caen stone corbels, filled in with panelling and intermediate joists. The entire are richly decorated with polychromatic devices, heightened with gilding, &c. In the hall and porch are a number of Irish marble shafts, which give a rich and varied appearance to the entire. The chimney-pieces of white marble have been carefully designed by the architect in accordance with the style of architecture, and have beautiful backs and hearths of Minton's encaustic tiles.

'The trimmings of the doors and windows are very elaborately designed, having jambs with arched mouldings, flanked with pilasters or standards, crowned with richly-carved poppy head terminations.

'The exterior is faced with English red brick, the ornamental positions being of limestone, the angles are all finished with slender shafts, having carved capitals and bases. The heads of the windows have the ogee pointed arches peculiar to Venice, with labels and intermediate voussoirs of limestone with a pierced cusp. The plain surface of the walls is enriched by bands of limestone. The bay windows are altogether of stone, and are a very beautiful specimen of workmanship, as are also the porches.

'The kitchen, offices, and stables are all designed in the same style of architecture as the house, and have fittings throughout of the newest and most approved patterns.

'The decorations and carvings have been all carried out under the directions of the architect, by Messrs. Dixon and Taylor of this town, and reflect the highest credit upon them.

'Next year it is the intention of Mr. Sandes to avail himself of the varied capabilities of his demesne to bring the grounds into an order befitting the beauty of the house.'

"Oak Park, we may remark, is not the only recent specimen of Cork talent which Kerry contains. The new entrance to Muckross (Col. Herbert's) was designed by the same architect (Mr. Atkins), and executed in marble obtained on the demesne; the gates, of a very elaborate design, by Mr. Perrot. Col. Herbert's new chapel at Muckross, too, is after plans by Mr. Atkins, executed by Mr. Evans; as is also Mr. Leahy's mansion, in the Romanesque style, beautifully situated over the lakes; the cut stone was the work of Mr. Egan. So that Kerry owes not a little to Cork ingenuity and talent, and we are glad to see that her gentry have the spirit to profit by them, while for the town of Tralee is claimed the credit of having supplied satisfactorily the accessories for which it was applied to."

PATENT PLUMBAGO CRUCIBLES AND FARRAR'S PATENT STEEL.

THE great difficulty experienced in the development of what may be termed the chemical process of manufacturing cast steel was the rapid destruction of the pots through the use of the fluxes previously deemed necessary to change the nature of the impure metal under treatment.

The fluxes used by Mr. Farrar, however, have not this inconvenience, and by the use of plumbago crucibles, to which we shall more particularly refer presently, he produces steel with greater facility and in much less time, from ordinary wrought iron, than it has hitherto been produced from blister steel. Phosphorus and sulphur, the two great enemies of the steel manufacturer, become powerless under Mr. Farrar's treatment, or rather, we should say, his treatment causes all phosphorus and sulphur to be thrown off upon a certain heat being attained. Hence the success which has been met with by him in America, in England, and in France. In America, the Damascus Steel and Iron Company, who use his patent alone, have received the most favourable testimonials as to the value of the steel produced; in England, Messrs. Beasley and Farmer, of Birmingham, have cast gun barrels from steel made of Staffordshire iron, and declare that, from its extraordinary tensile strength, they are superior to anything they have seen; and in France a commission was appointed by the emperor to inquire into the merits of the invention, and ascertain the adaptability of the metal for steel cannon, the result of which has been to prove that a first-rate article can be made from French iron, before considered quite unadapted for the steel manufacture—the more enthusiastic of those watching the experiments actually declaring the steel better than any of that made by Krupp, of Essen.

We have stated that difficulties have arisen from the destruction of the ordinary melting pots, but it seems that the patent plumbago crucible removes every obstacle, and that their great durability renders them actually cheaper than the common fire-clay pot.

The Patent Plumbago Crucible Company, by whom these new crucibles have been introduced, have received certificates of their working which at once prove that they are incomparably superior to all others. The refiners to the Bank of England state that they work to their entire satisfaction, and that 50,000 ozs. and upward have been melted in a single 1,000 oz. pot.

The master of the Paris Mint states that each crucible runs from 40 to 60 pourings of pure metal, and can with safety be dipped in cold water, when at a red heat, and used again immediately, as if it had undergone no change of temperature. This certificate is given after having exclusively used them for between two and three years; and Mr. Christie, of the Fyenoord Works, Rotterdam, says that they never crack in the furnace, which prevents the danger of losing the liquid metals, and that he has melted 1,239 kilos., consisting of pieces of cannon and copper, in one of the patent pots, whilst to melt the same quantity of metal would have required at least seven or eight German pots.

From all the facts which we can gather, it appears that the patent plumbago crucibles are capable of melting on an average from 35 to 40 pourings, are unaffected by change of temperature, never crack, can be used until they are thoroughly worn out, require only one annealing for several days' work, and become heated much more rapidly than ordinary pots, thus effecting a direct saving of more than 50 per cent. in time, labour, fuel, and waste.

It is needless to add anything to such facts as these, which we feel sure require but to be generally known to bring the patent plumbago crucible into exclusive use amongst steel manufacturers, engineers, brassfounders, and others.

LAW NOTES.

Delany v. *Sullivan.*—Action brought by plaintiff—a builder—to recover a sum of £28 10s. for work and labour, and materials, provided for the building of a wall and out-offices at the residence of the defendant. A sum of £18 10s. was lodged in court, and the defendant pleaded that no larger sum was due to the plaintiff. Verdict for plaintiff for full amount.

Carson v. *Tyrrell.*—Action brought by an architect against his client for recovery of fees at 5 per cent. Defendant pleaded a special agreement, which plaintiff denied. Verdict for plaintiff for full amount claimed.

THE O'CONNELL MONUMENT, GLASNEVIN.

We learn that by a recent arrangement between the Cemetery Committee and the trustees of the O'Connell Memorial Fund, it has been determined that the surplus moneys in the hands of the latter shall be handed over to the former, towards the expense of erecting a new range of vaults *within* the circle. Now, after the original object of the promoters had been so successfully realized in the erection of a suitably designed and admirably executed testimonial, we should not be disposed to take exception to the manner in which the surplus cash should be disposed of, if within the bounds of reason and justice to the contributors; but we certainly do enter our *caveat* against the proposed tampering with the site on which the structure rests, and which is a very important element in the *toute ensemble* of this — apart from political considerations altogether—very important national monument. The present circle is about 250 feet in diameter, surrounded by *a fosse*, and with suitable approaches leading from the main walk to the enclosure. We believe we are correct in stating that it formed part of the original design—when this circle was laid out—to construct around the entire of the circumference a range of family vaults; at least if it did not *then* it has certainly been very generally understood subsequently that such was to be sooner or later. So far so good! but the committee now purpose diminishing the diameter of the circle from 250 feet to about 128 feet, or in other words, to construct an inner range of vaults at a radius from the axis of the monument of 64 feet 4 inches; total diameter, 128 feet 8 inches. The proceeding proclaims a parsimony which—considering all circumstances, and more especially O'Connell's association with the foundation of this cemetery—to say the least is very ill-judged, and illustrates a *give-and-take-again* principle, not redounding to the credit of a public committee. The present space was awarded as the site on which the monument should stand; it is an essential accessory to its architectural beauty; and why, after the lapse of such a time, should it be lessened? As may be seen by reference to a former number of this journal,* in which a history of this cemetery and all particulars connected therewith were given, there is abundance of space contiguous thereto available for interment purposes for very many years to come, and, moreover, at a reasonable rent—considering the proximity to the metropolis—viz., £10 10s. per acre. The arrangement in question is, therefore, quite unjustifiable, and it becomes our duty, on principle, to apprise the public thereof.

ROMAN CATHOLIC CHURCH, MOATE (WESTMEATH).

Our illustration represents the new front, with tower and spire and side aisles, added to the existing church, after designs by Mr. J. J. M'Carthy, architect. Much praise is due to the Rev. Joseph Flood for his exertions in maturing this architectural work under the usual difficulties which beset such projects. The plan of the building as intended will comprise nave, 92 by 23 feet; aisles, 8 feet 3 inches wide; sacristy and tower at west end, as shown on illustration. The nave is the original structure, and the aisles are new. The spire rises to a height of about 116 feet. The walls are of rubble masonry, and the dressings of limestone.

GEOLOGICAL SOCIETY.

This excellent Institution held its periodical meeting as usual on the 12th ult. The members assembled in the new building, T.C.D., the Rev. Professor Haughton in the chair. Mr. Mallett, C.E., presented two specimens of oolite limestone from Ballina.

The Chairman, Mr. Kelly, and Dr. Apjohn examined the specimens, and agreed that oolite limestone was common in several parts of Ireland, in some districts it was noted for its durability as a building material.

Professor Kinahan exhibited some specimens of oldhamia antiqua from Bray Head, in which the double rows and the form of the cells composing them were well shown.

The Chairman stated that the society had received a valuable donation of fossil plants from William Harte, Esq., C.E., County Surveyor of Donegal.

The Secretary read a paper by Mr. G. C. Mahon on "Mining Operations, and the qualifications requisite for a Mining Engineer."

THE ROYAL HIBERNIAN ACADEMY.

A few months ago we announced that one of the desirable results of the somewhat recent investigation into the constitution of this establishment, would be the introduction of some additional architectural members into its councils; and we learn that this very desirable end is on the point of fulfilment, and only awaits the arrival of the charter to confirm the decision. Four additional academicians, chosen from the practising members of the profession in Ireland, will be elected; who, together with the *two* present academicians, will constitute the total—viz., *six*, provided for. With extreme gratification we chronicle this fact, and doubt not that it will directly or indirectly lead—independently of its other influences in the promotion of art—to the attainment of two very desired objects, frequently impressed by the Dublin Builder as essential—viz, the securing of a respectable architectural display at the periodical exhibitions of the Academy, and the re-organization of some institute or association to guard the interests of the profession in Ireland; it being to our minds an indelible stigma on our practitioners, as a body, that none such is in active existence. The names of the nominated academicians have reached us, but we should both be premature and guilty of bad taste were we at present to announce them; the selection is, however, such as the profession generally will endorse approvingly.

NEW HARBOUR LIGHT, PORT OF DUBLIN.

The Corporation for Preserving and Improving the Port of Dublin have decided on the erection of a new lighthouse at the south eastern extremity of the North Wall Quay, and we believe it to be in contemplation to remove the present structure, as also to construct the works of which we shall speak hereafter. The new lighthouse will comprise a tower of wrought iron 5 feet 6 inches in diameter, secured to a granite base, with a projecting cast-iron cornice sustaining a gallery and surmounted by a lantern of cast-iron, with domical top and gun metal frame. It will be lighted by a central gas burner with small apparatus. The external appearance of the structure will be neat and effective, and the plans and specification have been furnished by the engineer, Mr. George Halpin. The contract has been disposed of to Mr. E. Toomey, of Phœnix Iron Works, Parkgate-street, who has executed various works under the same board.

SCHOOL OF ART—ROYAL DUBLIN SOCIETY.

On the 21st ult. the distribution of the Society's and the Taylor Prizes took place in the Lecture Theatre, under the presidency of the Lord Justice of Appeal. It appeared from the report that "two students, Maria D. Webb and Harriette E. Harman, had obtained national medallions — the highest distinction conferred by the Department of Science and Art"; also that "six had obtained the reward of department prize studentship, twenty-five local medals, eighty first and ninety-nine second prizes, exhibiting an excess of seven in the total number of prizes last year. The receipts of fees presented a deficiency of £106 18s. 6d. as compared with last year, but the circumstance was attributed to the want of a second master for the first half of the session. Of the *Society's* prizes some were uncompeted for, viz., those of £7 and £3 respectively for *figure* class, and out of a total of prizes offered to the value of £31 only about half the amount, viz., £16, was gained. In the matter of the Taylor Prizes (already reported in the Dublin Builder) it was announced that the respective judges were Sir George Hodson on behalf of the National Gallery, Mr. Catterson Smith, Royal Hibernian Academy, and Mr. Macrory, Royal Dublin Society; but that for first prizes of £13 in oil, historical, there was *no candidate*; in landscape class for £10 prize was £7 awarded; in water colour class *no candidate*; in sculpture, prize offered, £10—awarded, £5; in architecture, prize offered and awarded, £7; oil landscape, £3!!! Total offered, £47; total gained, £25!!! Furthermore, the report states that "to two students, namely, Henry Crowley and Mary M. Almont, who were favourably mentioned by the judges, the executors have awarded extra prizes of £3 each; and the Fine Arts Committee conclude their report in this department with the following significant paragraph:—

"Although the works exhibited were not, in the opinion of the judges, as conspicuous in excellense as was expected, and although none of the competitors were deemed worthy of the scholarship of £20 or upwards, which was offered as the reward of high artistic talent, the committee have no reason to be dissatisfied with the commencement which has been thus made; and they confidently hope that when the nature of the endowment shall be better known, a more extended competition, and a longer and more careful preparation on the part of the students, will be aroused and encouraged in our Irish schools of art."

---

MORISON, LITH, DUBLIN.

WEST FRONT FOR THE CARMELITE CHURCH, MOATE.

THE LIBRARY
OF THE
UNIVERSITY OF ILLINOIS

THE POST OFFICE "ATROCITY"!

A MOIETY of the *presentation* already announced in the DUBLIN BUILDER as in store for the public, and emanating from no less important donors than the supreme postal authorities of this great kingdom, has already been unveiled, and may be viewed at *any* hour in the twenty-four with *intense* satisfaction by those who are proof against all nasty particularities in matters of art, and who can appreciate a *magnificent illustration* of "independent opposition" to a babbling multitude of know-nothings—with that noisy organ, the Press, as spokesman—under the portico of our (*once* classic) General Post Office. While in process of *manufacture* we particularized the constituent elements of this most remarkable work, and now, although only half matured, it stands out in *bold* relief before all previous *attempts* of a *similar* character; and—bestowed as it is so happily at this festive season, when "gifts" are all the fashion—it will leave an indelible impression on the minds of *at least* an important section of the public. Our feeble pen would be truly inadequate to a befitting description of its *tout ensemble*, nor indeed is it always good taste for a journalist to be too critical; but as some people—those who are always *most inconsiderately* meddling with officials, and questioning their *unquestionably* good (?) intentions about things that do not concern them—have actually had the assurance to pronounce the work in question an "atrocity," while again others proclaim it "a miracle of art," *we* should rather *not* assume the position of umpire between the two, but suggest for each of our readers to "go and see," so as to judge for himself. We may, however, remark *en passant*, that we trust there is *no* truth in the ungenerous report so industriously circulated, to the effect, that those ever vigilant professionals, distinguished for their digitous dexterity, have been impelled thither too frequently at the most *awkward* hour of *six o'clock*, p.m., when the numerous votaries at the "postal" shrine are admiringly contemplating the subject of our notice, and to the *very great inconvenience of the latter*.

THE CARTOONS OF RAPHAEL.

THE art-loving section of our public have now an opportunity of enjoying a rich and rare treat, in witnessing the original tapestries executed for the Emperor of Austria by this great master, after cartoons, and now, through the kindness of Mr. Charles Bianconi, J.P.—the fortunate possessor of these invaluable treasures—on exhibition for a charitable purpose, conjointly Protestant and Catholic, at the gallery of the (late) Royal Irish Institution, College-street.

The temporary custodianship, and the requisite arrangements for the above purpose, have been entrusted to Mr. Michael Angelo Hayes, a local artist of eminence, and moreover a gentleman much distinguished for his devotion and energy in the advancement of art. We dare not attempt to review the merits of works whose excellence defies criticism, and commands admiration which the most eloquent tongue should fail in describing, but the following brief sketch of their history (which, however, may be found *in extenso* in the catalogue) will be read with deep interest:—

These tapestries were woven at Brussels during the Popedom of Leo X., who commissioned Raphael to design cartoons therefor, and are seven in number, representing respectively, "The Miraculous Draught of Fishes," "Christ delivering the Keys to Peter," "Peter healing the Lame Man," "The Death of Ananias," "Elymas struck with Blindness," "The Sacrifice at Lystra," and "Paul preaching at Athens." After the tapestries were completed the original cartoons were for a long period disregarded, and left to moulder among the lumber of the manufactory, until taken possession of by Charles I., who caused them to be brought to England, and ultimately a gallery was built at Hampton Court by King William for their reception. The second set of tapestries executed after these cartoons were intended by Leo X. as a present to Henry VIII., and were accordingly hung up in Whitehall, and descended as a royalty to the succeeding monarchs; but after the death of Charles I. were purchased by the Spanish ambassador, who brought them to Spain, and after him remained in possession of the Dukes of Alva, until restored some few years since to this country by Mr. Tupper, our consul at Spain. The set now exhibited were executed at Arras, contemporaneously with the above, and were hung in the Imperial Palace at Vienna, until presented by the Empress Maria Theresa to Count Firmont at Milan, where they remained for many years, until lately purchased by Mr. Bianconi. We should strongly urge upon the consideration of our readers both the meritorious purpose and the excellence of this exhibition, which none should fail to witness.

PROTECTION OF LIFE FROM FIRE.

THAT "the burned child dreads the fire," and that "experience teaches," are two very popular proverbs; however it is seldom that a practical application of preventive measures follow as speedily in the wake of conviction of error, as it has done since the recent fatal occurrence at the Kildare-street Club house in this city, the particulars of which are so patent as to render repetition unnecessary. The want of a sufficiency of "fire-escapes," or perhaps, more properly speaking, the *total* absence of any such mechanical apparatus for the exigencies—nay, the periodical *certainties*—occurring in a large metropolis like this, justly called forth much indignant expression of feeling. Unfortunately, however, it was entirely confined to *verba non facta* (reversing the quotation), until one of those soul-harrowing catastrophes—which happily, at this side of the Irish Channel, "are but few and far between"—occurred, and awoke not only the philanthropic section, but the entire public to a sense of *duty*. Various meetings have recently taken place, at which this most important subject has been weighed in all its bearings; suggestion after suggestion has appeared in the daily journals (some very *original* indeed, but very questionable as to feasibility—however, being dictated by laudable intentions, we pass them by); but the practical application of energy to the task seems to have been reserved for a few gentlemen citizens, who succeeded in organizing a properly constituted body, entitled *The Royal Irish Society for the Protection of Life from Fire*, and which we are pleased to find has so far proceeded favourably with its mission, as to have secured the patronage of his Excellency the Earl of Carlisle—who, it will be remembered, took a lively interest in the sufferers from the fire above alluded to, and moreover was a substantial contributor to the fund—the presidency of Lord Talbot De Malahide, and the adhesion of numerous gentlemen of high character to act on the committee. As stated in the prospectus, we learn that "the society has ordered *four* fire escapes in addition to the one already entrusted to it by the Corporation;" and further, "that exclusive of the *original* cost of each machine—viz., £60—the annual expense of working will be about £80," figures which plead impressively the justice of a pecuniary consideration from *all* who wish *well* to the community at large; and it will be an everlasting libel on the City of Dublin if it be not voluntarily supported, especially as there is no Act of Parliament authorising the Corporation to defray the expenses out of the civic resources.

FEMALE ORPHAN SCHOOL, BURLINGTON-PLACE.

EXTENSIVE additions, together with considerable internal alterations, have just been completed to provide increased bedroom accommodation for an extra number of pupils, together with an infirmary, bathrooms, w. c., boardroom, dining-hall, laundry, drying closet, &c., at this admirably conducted and most laudable Institution. The works were carried out under the directions of Mr. M'Curdy, architect, by Mr John Nolan, of Meredith-place, builder, and at an expenditure of about £1,000.

PROPOSED ARCHITECTURAL ASSOCIATION AT MANCHESTER.

A PRELIMINARY meeting has been held by the professionals in this manufacturing emporium with a view of establishing an association, and which was ultimately resolved on, and all preliminaries, as to rules, office-bearers, &c., arranged.

MEMORIALS.

A PROJECT somewhat akin to that now on the eve of being realized in honour of the late Sir Philip Crampton, Bart., Surgeon-General, is on the *tapis* as regards the late Sir Henry Marsh, Bart., Physician-General, and Merrion-square has been spoken of as the probable site. A correspondent of the *Irish Times* also advocates the claims of the late Surgeon Richard Carmichael for a similar honour, and we would add that of Dr. Graves likewise. However, in plain truth, we must say that the Colleges of Physicians and Surgeons respectively are the most fitting repositories for these memorials, which may be regarded as strictly of a professional character.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary general meeting was held on the 18th ult.—Mr. F. W. Porter in the chair. A donation of Owen Jones and Warren's illuminated volume, entitled "Paradise and the Peri," was announced. Allusion was then made to the deaths of the Earl of Aberdeen and Mr. Samuel Ware, both members. Mr. T. Roger Smith then read a paper on "Acoustics." Mr. Scott Russell offered some remarks relative thereto, and concluded by proposing a vote of thanks to the author, which was seconded and passed unanimously.

SAINT JAMES'S PAROCHIAL CHURCH.

THE Irish Metropolis compared with any other city of equal magnitude and importance in the kingdom, has always been pre-eminently deficient in the architectural character of her religious edifices, especially those in the Gothic style; but of late years, happily, a progressive movement—although as yet only in a positive degree—*has* taken place, and we trust that the good example thus afforded will serve to stimulate those who yet linger in the path of apathy. One of the most important recent works of this class to which in our periodical notices we are enabled to call attention, is the Parochial Church of St. James, an entirely new structure, save where partly erected on the foundation of the former building, which was quite unsuitable to the requirements of a largely increasing congregation. The Ecclesiastical Commissioners—a body which we take occasion to remark, scarcely receives one-half that share of public appreciation to which its energetic action in the matters of church restorations, preservations, and erections, justly entitle it—having determined on razing the old church and rebuilding it after more orthodoxical fashion, instructed their late architect, Mr. Joseph Welland, to prepare the requisite drawings. Those who knew that estimable gentleman and truly competent professional, could—as we did at the time—at once anticipate that the work in question would bear the *impresse* of his usual ability; and although the mind that conceived the design passed from its earthly tenement prior to the realization, we can reasonably assume—judging from our own feelings under similar circumstances—the great gratification sure to be experienced, if it now existed, at the admirable and faithful manner in which the builder, Mr. Thomas Henry Carroll, has subsequently fulfilled the architect's intentions in every detail. We carefully inspected the entire structure on the 31st ult., and unhesitatingly pronounce its execution to be such, as the most critical professional should commend. The following is a brief description:—

In plan the church is cruciform, with nave 76 feet by 28 feet, one aisle 46 feet by 15 feet, transepts 66 feet 6 inches by 20 feet, chancel 20 feet by 18 feet, robing-room and tower at south-west angle 10 feet square in clear, through which an organ gallery at west end is approached by a cleverly contrived stone staircase, and a special winding stairs for the bell-ringer is also provided in an angular buttress. The nave is approached by two spacious doorways—one at west end and another in the tower,—and is separated from side aisle by an arcade of three pointed arches springing from cylindrical piers, with moulded caps and bases, as also from chancel by a lofty and graceful arch; all of which are executed in Caen stone. An organ gallery occupies the western extremity, and is fitted with a beautiful instrument by Messrs. Bevington, of London. The roofs are of open timber work, stained and varnished, and are effective especially at the intersection of the transepts where the trusses unite. Of the furniture—which is characteristic, but comparatively simple throughout, the benches being commodious and with plain ends—we would specially note the design and execution of the pulpit, composed of Canadian walnut, as is also the lectern and chancel railing. The height from level of church to the apex is about 48 feet, to hammer beam 36 feet, and to wall plate 23 feet, producing graceful proportions. Viewing the exterior, the south elevation which presents itself towards the old entrance gateway, the position of which is, we understand, to remain the same, exhibits at one extremity the tower and spire, and at the other a wing of the transept, with the intermediate wall of aisle pierced by three traceried windows, as also the flank of chancel and clergyman's entrance porch. The roof of aisle being a lean-to, there are no clerestory windows. In features the north and south transepts are identical, each having a handsome traceried window, 19 feet by 10 feet, with a quadrilateral open in-gable, angular buttresses, and *no* finial. The north elevation is similar to the south, except that having no aisle it has tall traceried nave windows. The east end displays a great triple window with corresponding tracery—the centre open being two light and the sides single ditto, we presume intended *hereafter* for stained glass—the small gable of vestry and its three light window, also a side transept window similar to those of aisle. At western end is the entrance doorway with bold mouldings, detached shafts, and decorative iron work. A triple trefoil headed great window above same lights south nave; and the tower,—which is placed at the west angle and divided into four stages with belfry lights in each—has massive angular buttresses, and terminates with a broached spire attaining an altitude of 120 feet, perhaps, considering the level of the site, presenting the highest landmark the city can yet boast of. The masonry throughout is of Calp rubble, with horizontal beds and irregular joints; and the dressings, strings, corbels, water tables, mullions, and tracery, &c., are of sparrow picked or tooled and chiseled, or otherwise dressed, limestone from the builder's own quarries at Ballinasloe: a stone which by the way we would recommend to the notice of our professional readers. Especial care seems to have been paid to the warming and ventilation of this building, a fact which the congregation will no doubt highly appreciate, and two large and handsome stoves by Messrs. Musgrave, Brothers, of Belfast, with horizontal flues communicating with the exterior are introduced. The expenditure is about £6,000, and the sum seems very moderate for so commodious and handsome an edifice. Mr. Carty is the conducting foreman.

JOTTINGS IN CORK.

WE were pleased to see on the occasion of a recent visit to this city, more activity manifest than when we sojourned there last July, and amongst other matters note the following:—

The new Scots' Church in King-street is about ten feet above ground level; the architect is Mr. Tarring, of London; the builder, Mr. Richardson, of London; clerk of works, another Londoner. We are informed that the proceedings connected with this competition are likely to provide some work for the gentlemen of the long robe at the ensuing assizes.

The scaffolding for the erection of the portico to the Dominican Friary church, Pope's-quay, is completed, and the fixing of the columns will proceed forthwith. It is intended to finish the front according to the original design, with a hexastile Ionic portico and lanterns on the wings. The architects are Messrs. Deane, Son, and Woodward; the contractor being Mr. Scannell.

The reformatory for juvenile criminals at Upton is now ready for the reception of inmates, having been inspected by the Government official. The total cost has been £3,500, including furniture. The architect, Mr. R. Brash; contractor, Mr. R. Evans.

Extensive alterations have been made in the city club house; the entire front has been re-faced in Portland cement, and a new wing built after designs by Sir John Benson, architect; contractor, Mr. Daniel Barret.

A society has been formed for erecting dwellings for the working classes, and a plot of land taken at the north side of the city, whereon it is intended to erect sixty cottages. Tenders have been advertised for. Mr. Richard Brash is the architect.

The Messrs. Newsom are erecting a large block of buildings in Patrick-street. It is a pity that so excellent an opportunity was lost of suitably embellishing the locality, as no expense seems to have been spared by the proprietor. The contractor is Mr. B. M'Mullen. This is the structure referred to in the last number as being fitted with Messrs. Clark and Co.'s patent shutters.

The works on the Cork and Kinsale Junction Railway are being radidly proceeded with; the first five miles are entirely completed and ballasted. Messrs. Trowsdale and Sons, contractors. Two rival companies are in the field for the honour of making a railway from Cork to Macroom, 24 miles. One proposes to construct a line at the north side of the Lee, to form a junction with the Great Southern and Western at Blarney. The other is proposed to run at the south side of the river, and to form a junction with the Cork and Bandon line about two miles from Cork.

SKETCH OF THE LIFE OF RAPHAEL.

THIS sublime artist was the son of a painter named Sanzio, but of indifferent merit, and was born on Good Friday, 1482. He was employed by the Popes Julian II. and Leo X., who loaded him with wealth and honours, and the Cardinal De St. Bibiana held him in such high estimation, that he offered him his niece in marriage, but he declined this honour from an expectation he entertained, founded upon the promise of Leo X., of being made a cardinal himself. His pictures are to be found principally in Italy and Paris. That of the *Transfiguration*, preserved at Rome in the Church of St. Peter Monterio, is reckoned his masterpiece. His person was handsome, and his manners were polite, affable, and modest, though he lived in the utmost splendour. He was not only the best painter in the world, but perhaps the best architect too, on which account he was employed by Leo X. in building St. Peter's Church at Rome. This engagement prevented his acceptance of an invitation into France from Francis I., for whom he had painted a *St. Michael and the Holy Family*, and had been remunerated by that monarch with sums so far beyond his expectation, that he resolved to show his gratitude by a performance in which he even surpassed himself. This was the *Transfiguration* above alluded to, intended as a present to Francis; but he died before the picture was quite finished, and it was detained at Rome. His death happened on his birthday, 1520, when he had completed his 38th year, the consequence of his passion for the fair sex and the injudicious treatment of his physicians. His celebrated *Cartoons*, for which Louis XV. offered £100.000, were purchased by Rubens for Charles I., and brought to England, and have successively graced the Palaces of Hampton Court, Buckingham House, and Windsor Castle. A considerable jealousy existed between this artist and Michael Angelo, which sometimes manifested itself in a manner not very creditable to either. Raphael frequently exercised himself in sculpture, and excelled as much in it as in painting and architecture. A *Jonas*, of the size of life, which is deemed his *chef-d'œuvre* in this line, is shown in the Chapel of Madonna del Popoli at Rome, the cupola of which he also painted.

THE CHOIRS OF OUR CATHEDRALS.

THE Rev. Henry DeBurgh takes exception, and very justly, to the musical excellence of our cathedral choirs as compared with those of former days, and says :—

"I have frequented the College Chapel, Christ Church, and St. Patrick's, at intervals for upwards of 25 years, and have myself witnessed the decline and fall of their music. The old system gave us such men as Spray, Stevenson, Jager, Baggine, Dr. Smith, and the Robinsons (and you were pretty certain to find each of them in their places at the three services); the present system has given us —what?—Let those who go judge for themselves. I have heard them three or four times lately, but without the smallest pleasure. I go mechanically, and from old association; but the singing is very inferior and the whole system wrong. How long is it to continue?"

THE OLD ROMAN WALL ROUND LONDON.

What species of cement or mortar was used in the construction of this wall, of the wall of Severus, and generally of all our most ancient ruins, we possess no clue; but it is certain that no modern buildings have the same advantage. Our ordinary houses are ready to fall to pieces before they are well completed; and even more pretentious structures look old and decayed in a few years; especially the mortar crumbles away from the brickwork when it is scarcely dry, while, on the contrary, the cement used by the old masons soon became as hard as the stones or flints it connected. Traditions, chronicles and histories ascribe a very early date to the city wall. The metropolis, according to Simeon of Durham, was first inwalled by Helen, the mother of Constantine the great, A.D. 860. The Danes burnt London in 839, and Alfred restored it in 886. In 994 the citizens suffered siege from the Danes, closed their gates, and were defended by King Ethelred within the walls. Fitzstephen, writing in the days of Henry II., says: "The wall is high and great, well toured on the north side, with due distance between the toures, on the south also the city was walled and toured; but the fishful river of Thames with its ebbing and flowing, hath long since subverted them." In King John's reign, A.D. 1215, the barons repaired the walls and gates with stones taken from the Jews' houses, and in 1257 the walls were again repaired by Henry III. The cost of reparation was met by tolls and customs granted by the Crown. In 1477 Ralf Joceline, mayor, caused the wall to be repaired between Aldgate and Aldersgate. Alluding to this, Hollinshed writes, (A.D. 1447): "By the diligence of Ralf Jocelin, Mayor of London, the wall was made betwixt Aldgate and Cripplegate. He caused the Moorfields to be searched for clay and bricks, to be made and burnt there." He caused chalk to be brought out of Kent, and burnt into lime for the furtherance of the work. The Skinners' Company did the work between Aldgate and Bevis-marks; the Drapers between Bishopsgate and All hallows, and the wall nigh unto the Postern, Moorgate. All the companies took their part in the patriotic labor. The entire circuit of the wall was 10,608 feet, or two miles and 48 feet in extent. Think of our mighty London being hooped within a wall of two miles in circuit!—*City Press.*

Notes of New Works.

A coastguard station, consisting of eight dwelling houses for men and a chief officer's house, is to be built at Baldoyle, Co. Dublin, after plans furnished by the architect to the Board of Public Works.

Tenders have been received by the War Department in Ireland for improving the drainage at Newbridge Barracks.

A new railway station is to be built at Lisbellaw.

A new convent for the Sisters of Mercy is being commenced at Newry after plans by Mr. John Bourke, architect; Mr. William Byrne, of Newry, the builder. The expenditure will be about £4,000.

Estimates are required to this date for certain works to be executed on the Lower Commons of Bray, according to plans by Mr. Frith, C.E., County Surveyor.

The top stone of the new church of Gorey has been laid, the interior is completely finished.

A large station with goods store, &c., has been erected for the Dundalk, Enniskillen and Londonderry Railway Company at Cootehill, Co. Cavan, after plans &c., by the Company's Architect, Mr. William G. Murray. The former building comprises the ordinary internal arrangements of booking office, waiting room, station master's residence, &c.; and externally presents a tasteful elevation of early English character with two gabled wings connected by a central covered porch. Material for walling, hammer dressed random ashlar, with Cairnmore sandstone dressings. Expenditure about £2,000. Mr. John Nolan, contractor for this and various other of the Company's stations, &c., &c.

The Kilkenny Junction Railway will be speedily commenced, as preliminary preparations have been completed.

At St. Vincent's Reformatory, Goldenbridge, a second laundry has been commenced. The laundry already built is the most complete in the United Kingdom. All the operations of heating water, drying, cooking, &c., are performed by means of steam. The success of this establishment for the reformation of adult convicts has been complete. Since its foundation a second reformatory for females, under the age of sixteen, has been connected with it; but it being essential that the junior inmates should not be allowed to mix with the adult convicts, it has been found necessary to erect a second laundry, on a smaller scale. This will form a portion of a future quadrangle, about 120 feet in length, and will contain laundry, mangling, ironing, drying, stoke and boiler rooms; the drying, &c., will be performed by hot air. Cost, about £1,000. Mr. John Bourke, architect.

At the Dominican Convent, Kingstown, a similar laundry, somewhat smaller in size, is about being erected. At this convent there has, about 12 months since, been erected very extensive schools, at a cost of over £2,000; also an addition to the convent, containing large schools, dormitories, infirmary, kitchen, offices, cells, &c., at a cost of £2,200; same architect.

The Rev. Provost, T.C.D., has, we understand, disposed of a portion of his property at Dalkey, near Sorrento-terrace, and locally known as "the View" Rock, to the Government for the purpose of having a coastguard station erected thereon.

A new Roman Catholic Church is to be built at Kilcock, county Kildare; Mr. J. J. M'Carthy, architect.

The new church of St. Saviour, Dominick-street, will be consecrated and opened for Divine worship on the 15th inst.

The Ballast Corporation are about erecting a thirty tons crane on Sir John's-quay. Touching this, we may remark that complaints have reached us from some of our advertisers—English and Scotch stone merchants—to the effect that when they imported blocks of more than ordinary size to Dublin there was no crane sufficiently powerful to raise them. The necessity for improved accommodation is therefore obvious.

At the Dominican Convent, Cabra, there have been recently erected extensive additions, at a cost of £8,000, including kitchen, offices, work-rooms, community-room, chapter-room, infirmary, dispensary, &c., and 26 cells, together with a second campanile, 85 ft. in height. These, with the extensive additions of chapel, schools, &c., formerly erected, make this by far the most extensive conventual establishment in the United Kingdom. The north front presents a façade of 250 feet in length, broken into three compartments by two campaniles. Mr. John Bourke, architect.

A new church has been consecrated at Nenagh; style, Gothic, with neat tower and spire. Internal arrangements comprise nave, aisle, and chancel, affording accommodation for about 450 persons, and having appropriate fittings. At west end is a gallery, in which an organ, by Messrs. Telford, of this city, is erected. In the chancel a memorial window by Moore, of London, has been placed by J. J. Poe, Esq., in honour of the late rector, his father. Mr. Hunter, of Bandon, was the builder.

Mr. Alexander Thomas Gordon, of London, has entered into a contract with the directors of the Newry and Armagh Railway, to complete that line to Armagh.

The Committee of the Exhibition of the Fine Arts and Ornamental Art to be held in 1861 in connection with the Royal Dublin Society, are about erecting a gallery in the Agricultural Hall, and will receive tenders for same up to the 8th inst.

A new Roman Catholic church has been built at Chelsea, London, after designs by Mr. Welby Pugin, architect. It presents some noteworthy features as thus described by the *Building News*:—"The chapel is divided into three bays, with groined intersecting ribs, having carved bosses at each intersection, the principal ones representing the Sacrifice of the Mass, the Resurrection, and the Blessed Virgin seated on a throne surrounded by angels. The ribs are supported on elaborately carved caps which terminate eight Galway green columns arising from a polished alabaster base. The walls are formed of Sicilian and Devonshire marbles. The chapel is lighted from four hexagonal tracery windows which break into the upper portion of the groin. The altar is a most highly finished work, in the centre of which, and standing immediately above the altar, is the tabernacle of polished alabaster, inlaid with spars and other coloured marbles. The cresting round the arch is formed of cunningly cut passion-flowers, interwoven with conventional foliage. Above this is a throne for the reception of the monstrance, round which, and forming a canopy too, is a biscica of angels adoring and holding instruments of the Passion. In the centre of the panel will be an I.H.S. in embossed metal-work with rays and stars The cresting is formed of angels interwoven with leafage. The upper portion of the reredos is supported by marble and porphyry columns, between which are carved clusters of foliage, and the side panels are also adorned with angels. The principal portion is worked in alabaster, the altar frontal is wrought in Caen-stone. the chief subject being the Adoration of the Lamb The metal-work, we are told, is being exeuted by Messrs. Hardman, and is said to be extremely rich. The chapel is connected with the present church by means of an arcading supported by marble columns. The work is executed by Mr. Farmer, of Mead-place."

MEMORANDA IN AMERICA.

The new city hall, Cincinnati, was dedicated on the 5th ult., and is said to be a splendid building.

The public libraries in Philadelphia contain 271,981 vols., and those of the State, 467,716.

A new and splendid cemetery is to be opened near Havanna, to which the remains of Christopher Columbus, the discoverer of the New World, are to be removed and deposited in a silver urn, upon which will be inscribed, in letters of gold, the most remarkable events of his great enterprise. A bronze statue of the discoverer, in the attitude of revealing his mission, is to be placed over them.

Cast-iron buildings are very much in vogue in America; one at Milwaukee, at corner of Eastwater and Wisconsin Streets, is said to be most imposing and magnificent.

Scientific and Artistic Morceaux.

The progress of the railway works from Castlerea to Ballyhannis is said to be rapid. The permanent way from the former town to the River Suck is completed, and the bridges over that river finished; the remaining portion of the work being in a forward state.

An elegantly designed stone cross from the chisel of Mr. Fagan, who is at present engaged on two statuettes of the Queen and Prince Consort, has been presented to Gorey Catholic church by Sir Thomas Esmonde.

Paul Delaroche's last great work, "The Martyr," has been for some time exhibiting at Mr. Lesage's gallery in Sackville-street.

A pneumatic tube, for the transmission under ground of the letters, &c., from St. Martin-le-Grand to Bloomsbury district post-office is being laid. It will be two and a-half feet in diameter. We have no doubt that a few years will witness the exclusive transmission of the mails throughout the kingdom on this principle.

It is proposed to connect Regent's Circus with the Metropolitan line at Smithfield, by means of a tubular underground line of rail.

The Madras pier works are rapidly progressing. and passengers can soon be landed and embarked beyond "the surf." The profits of the boatmen will be seriously curtailed.

Some of the monuments in the Dutch burial ground at Negapatam, Madras, were erected from 200 to 250 years ago, and the inscriptions and coats of arms engraved thereon are in an excellent state of preservation, the masonry work only needing repair. It is proposed to establish a new library and reading-room at Vizagapatam.

The Emperor Trajan, at the beginning of the second century, erected a bridge over the Danube that equalled in size the Victoria bridge of the present day. It was 60 feet wide, 150 feet high, and nearly two miles in length.

The bronze statue of honour for the Guards' memorial in Pall Mall, and cast by Messrs. Elkington, Mason, and Co., of Birmingham, from cannon taken by the Guards, has been fixed in position.

Mr. Aston, *a barrister*, is the inventor of a new mode of propelling steam vessels by means of smooth discs of wood or metal immersed some two feet and driven at a high velocity.

A plan for constructing the proposed public offices in London along the river, and connecting Somerset house with Whitehall and the houses of Parliament, has been submitted to the First Commissioner of Works by Sir Richard Bromley.

The indefatigable Mr. Train is pursuing his horse tramway project with much success in London, and has obtained the sanction of several vestries.

An engraving of the Castle Chapel Pulpit, in this city, designed and constructed by the eminent firm of Hardman & Co., was given in the New York Architects' and Mechanics' Journal of the 15th December.

Steam fire engines are in America rapidly superseding the old hand machines.

The London and North Western Railway Company, in a new bill proposed to be laid before the Legislature next session, seek amongst other matters for permission "to purchase, take, hold, &c., certain land and buildings at the North Wall, Dublin, lying between North Wall, Wapping, and Mayor-streets, and Royal Canal Docks.

In the recent competition held in Liverpool for the boys' orphanage of that town, the committee have chosen the designs submitted by Mr. Pugin. The other competitors were Mr. Charles Hansom and Mr. Hughes.

Miscellaneous.

THE AGRICULTURAL WINTER SHOW.—This annual exhibition was held in the large Agricultural Hall of the Royal Dublin Society, on the 11th, 12th, 18th, and 14th ult., but the display was scarcely an average of that usual at this period of the year. Amongst the exhibitors of implements, engines, &c., we noticed Messrs. Barrett, Exall, and Andrewes, Garrett and Sons, Mr. Woods, Shekleton, Dundalk; Kennan, Dublin; John Maguire, ditto; and others, who respectively sustained their well-established reputation.

DUBLIN AND HOLYHEAD.—The Admiral Moorsom, a fine steamboat built by the London and North Western Railway Company, is being placed on this station.

DISCOVERY AT ST. DOULOUGH'S CHURCH.—Mr. Sloane, C.E., Honorary Architect to the Committee for St. Doulough's Church restoration, reports that a square-headed doorway leading to the church, and immediately beside the hagioscope, has been discovered in the prosecution of the work. Mr. S. says "this bears out the supposition of one of our secretaries (Dr. Reeves) that there was a *more ancient* building than any now standing to which the erection of the present building was made subservient, and may account for the incongruities—the levelling off of Leper's window especially."

PLEASANT FOR WOOD ENGRAVERS!—The last number of the *British Journal of Photography* contains a photograph from nature of the "Porch of Strasbourg Cathedral." It is printed with ordinary letter-press from a block produced by photography and electrotype, untouched by the graver. The invention is by Paul Pretsch, and is for illustration, such as is now in common use with woodcuts.

EXTRAORDINARY TIMBER.—Messrs. Robertson, Donaldson, and Co, timber merchants, Victoria-street, lately made a purchase at Liverpool, of two of the most extraordinary logs of timber, for size and quality, that were ever brought into the city, while they were the smallest that could be found in the cargo from which they were selected. The timber is New Zealand pine from Kauri, where immense forests, of probably a century's growth, have been discovered. The logs alluded to are of the following dimensions:—The first measures 50½ feet in length, is 26½ inches square, and contains 246¼ feet of timber. The other is much smaller; it measures 26 feet in length, is 28 inches square, and contains 142 feet. Some of the logs in the cargo were from 70 to 80 feet in length; and some idea of the immense height of the tree, as it stood in the forest, may be formed from the fact of this great length being, in many cases more than 26 inches square. The timber is of a fine hard texture, and is remarkably free from knots. The logs in question are the first New Zealand pine that has ever made its appearance in Perth.—*Perthshire Advertiser*.

JONES'S HEATING APPARATUS.—We are requested to print the following testimonial received by the patentee from Lord Charleville's head gardener:—"Charleville Gardens, Tullamore, Ireland.—To Mr. J. Jones.—Sir—I have much pleasure on being able to inform you of our entire satisfaction testing apparatus, as supplied by you in December last, for the pine stoves, lately erected by the late Lord Charleville. Your saddle boiler does its work quickly and well; we can command any amount of heat, top and bottom, and in the shortest time, throughout the whole range. I have seen several of the newly-invented boilers, and have had to do with some of them, but for hard work give me the simple, but durable and efficient saddle boiler. I must also beg leave to inform you that your plan and instructions for fixing and arranging it are truly excellent; it was so easy to my man employed in fixing the apparatus that he had the whole arranged and fixed in half the time it would have taken him had he not had your plan. With so many hundred feet of pipe, I thought at one time we should have to work our boiler very hard; I have, however, great pleasure in saying we have found it quite the reverse.—Yours respectfully (signed) JOHN ROBERTS."[*]

THE UNHAPPY HOMES OF ENGLAND.—A French author recently published a work on the condition of England, in which the revelations of socialism are astounding.

MEDAL TO DR. JACOB.—The medical brethren of this distinguished Oculist, and proprietor and editor of the *Dublin Medical Press*, have caused a bronze medal to be struck in his honour, bearing on one side a likeness of the Doctor, and on the other the following inscription:—"Arthur Jacob, M.D., F.R.C.S., Prof. of Anat. and Phys., Roy. Coll. of Surg. in Ireland. In commemoration of eminent services rendered to Science and the Medical Profession in Ireland, 1860."

LONG RAILS.—Messrs. Barningham, of Darlington Ironworks, are rolling a large quantity of rails 27 ft. long and 92 lb. to the yard. Railway companies discover that, by having strong rails and heavier engines, immense trains of minerals and goods are worked with less labour, greater dispatch, and at smaller cost. In fact, one train will do the same amount of carriage as three usually did.

---

[*] Particulars may be seen elsewhere in advertisement.

THE PATENT SELF-REGULATING WIND ENGINE.—We are requested to state that one of those useful machines has been erected on the estate of the Earl of Howth, at his quarries on the high road between Baldoyle railway station and Howth. The numerous parties who have been making enquiries, or who have deferred giving their orders, have now an opportunity of seeing the Wind Engine in working order, and of judging of its efficiency.

FIRE-ESCAPES.—The old adage, "*experientia docet*," seems to have been illustrated in the recent energetic attempt to provide suitable fiire-escapes for this city, and we are glad to see that the movement has been at least so far substantially encouraged.

THE STREETS OF PARIS.—Several houses are about to be demolished in the neighbourhood of the Boulevard de Sebastopol, to continue the Rue Turbigo. That street will branch off from the Rue du Temple, near the Boulevards, to the Chateau d'Eau, and establish a direct communication between that point and the Church of St. Eustache, near the Halles. It will be about 1,200 metres long, by twenty wide. This project, added to others which are in course of execution, will have for result the complete transformation of the most densely populated quarters of the capital, where free traffic is now frequently interrupted.

IRISH ARCHITECTS IN NEW YORK.—We learn from the *Architects' and Mechanics' Journal* that "a large building, two lofty storeys in height, 60 by 100 feet, is to be contracted for and commenced during the fall. It will be in the Venetian style, with a front of Philadelphia brick and heavy Dorchester stone trimmings, 56 feet high from the ground to the top of the cornice. Mr. Chas. Mettam (formerly of Dublin), architect."

A HINT TO WORKMEN.—At a recent meeting of the National Association for the Promotion of Social Science, Lord Brougham remarked that a working man out of debt, acquiring capital, however slowly, and abstaining from stimulants, is on the road to happiness, and with a prospect of attaining it as bright as is vouchsafed to any citizen of the State, even the highest in the land.

IMMENSE GRANITE BLOCKS IN THE AMOOR.—About half a mile to the west of our encampment were heaps of rounded granite blocks, strewn over a sandy shore; also several isolated masses, varying from 100 to 800 feet in height, were standing about 60 yards from the base of the precipices. The sharp angles on all these masses had been worn away by water, and the cliffs at this part were much undermined, in some places forming recesses 40 and 60 feet deep. At one place I found a great triangular-shaped mass, 130 yards on its sides, and about 450 feet high. This was pierced through by natural arches, formed on each face, 82 yards wide, and of greater height, leaving the upper part standing on three great abutments. The scene was strikingly grand; and while I was sketching this beautiful object, the sun rose, and I beheld part of his crimson orb through one of the natural arches, giving quite a magical effect to the landscape. Nature had completed this structure thousands of ages before the monks of Crowland built their triangular bridge.—*Atkinson's Travels in the Amoor.*

CEMENTATION OF IRON.—The process by which iron is converted into steel generally consists in making it combine with a small quantity of carbon; and very frequently, owing to the brittleness of steel when tempered to the highest degree, it is desirable to give the qualities of steel to the surface only of a bar of iron. This is done by enclosing it in a box of sheet iron, filled with charcoal dust or horn shavings, tallow, &c. Here the question naturally arises, whether carbon combines with the metal under a solid form, which is scarcely admissible, or else is absorbed in the shape of some carburetted gas; and, in the latter case, it is useful to know what gas is generated in the process. On this subject M. Caron has just addressed a paper to the Academy of Sciences, in which he describes several experiments of his to show that the cementation is owing to the formation of a cyanide, cyanogen being, it is well known, a compound of carbon and nitrogen. Having filled a porcelain tube with fragments of charcoal surrounding a bar of iron, and exposed it to the heat of a reverberatory furnace, he successively caused hydrogen, oxide of carbon, azote, air, pure carburetted hydrogen, &c., to pass through the tube, but could not after a two hours' fire obtain any degree of cementation. But the case was far different when he made a current of dry ammonia pass through the tube; in that case the cementation was effected rapidly and easily; after being exposed to the fire for two hours the bar of iron being immediately tempered, then hammered to make the grain closer, and then tempered once more, proved, on being broken, to have been cemented to a depth of two millimetres. This result M. Caron attributed to the formation of the cyanide of ammonium, and further experiments confirmed this idea. M. Caron then, in order to obtain cyanide of potassium in his tube as a cementing agent, let his charcoal soak in a solution of carbonate of potash, and the experiment succeeded beyond expectation. In the same manner he obtained excellent cementations by employing soda, barytes, and strontian, under the influence of a current of air. Hence he shows that all the various nostrums used in metallurgy for cementing iron owe their efficacy to the formation of cyanides.

BRITISH BUILDING STONES.

IN an article under this title the *Builder* (London) particularizes the produce of several quarries, amongst those the following, which we are requested to note:—

"The *Dean Forest* quarries, in Gloucestershire, belong to the coal measures: their chief outlets are at Lydney, Coleford, Bream, and Yorkley. The local name of the stone is merely Dean Forest stone. Much of it is suitable for dock and railway purposes, builders, statuaries, paving, &c.; grindstones, troughs, &c. It was used in the construction of Newland Church and other old churches, in some of which the carving on the oldest graves and pinnacles is as sharp, clear, and defined as when first worked 400 years ago. This stone was used in the construction of Newport, Cardiff, Gloucester, and Swansea Docks; South Wales, Taff Vale and Western Valleys Railways; Gloucester and Berkley Canal; Gloucester Over-bridge; Folly-bridge, Oxford; Cardiff Castle, and National Provincial Bank; Marlborough and part of Llandaff Colleges; Assize Courts, interior of St. John's and Exeter Colleges, and Taylor and Randolph's Buildings, Oxford; Eastnor Castle and Whitley Court, Worcester; Langton House, Oxford (steps 18 feet long, and landings proportionate); and the towns paved with it are too numerous to mention. It is also manufactured into field and garden-rollers, pillars, &c. On Birch-hill an unlimited quantity can be obtained for ages to come. About 150,000 cubic feet were raised in one of the quarries by Messrs. Hemmingway & Pearson for Cardiff Docks, a great portion of which came from quarries now in possession of MESSRS. GRINDELL & Co Blocks of any size possible to be removed are easily obtained here, as also steps, landings, and grindstones. The Birch-hill and other kinds are sold in blocks, rough, at 7s. per ton; is pecked or scappled, at 7d. to 8d per foot cube; common building stone, 1s. per ton; flagging, from 2d. to 2½d. per foot superficial; troughs and cisterns, 6d. per gallon of 281 cubic inches; gravestones, 6d. per foot superficial; grindstones at 2d. per inch diameter, up to 2 feet high; 7 feet about £5."

THE PANTOMIME—THEATRE ROYAL.

"CHRISTMAS *comes but once a year; and when it comes it brings good cheer*," is a familiar proverb, which the happy faces of both "*old*" and "*young*" juveniles who eagerly long to see—and when seen enjoy to all intents and purposes—the Christmas Pantomime, more forcibly illustrate than any other event which at this festive season takes place. Who has not heard of "Jack the Giant Killer," of "nursery-rhyme" notoriety? and what member of that happy community commonly called "*children*"—but who in the beauty of their innocence often read worldly-worshippers, mammon-seekers, and would-be sages a wholesome lesson of *natural* wisdom—has not by this time used their best influence with *pater* or *mater familias* to allow them one peep at that "wonderful Jack," so often depicted in glowing colours in those pretty story-books? And here, so perfect is the illusion, so characteristic the scenery, so admirable the personation, of "Jack," with his seven-leagued boots, his deadly weapons, his stratagems to entrap and slay those "terrible giants," that, judging from the wondering countenances of "the little ones," credulous adults would be almost led to imagine that the "veritable Jack" was in reality pursuing his tragical career under the roof of "the Royal." Unfortunately we cannot now enter into a lengthened criticism of the merits of its production, but it may suit our purpose and that of the Lessee—who, whatever he does in the catering line he does well—to say it is the *best* pantomime, as regards scenery, music, plot, genuine drollery, appointments, &c., that has been put on the stage *here* for many years. We must also *en passant* note, that in the comic department, through a coincidence, is introduced a view of Messrs. Sheils and Scott's front in Westmoreland-street (of which the conductor of this journal was the architect), travestied, however, into a toy-shop, in which clown and pantaloon cut their usual capers.

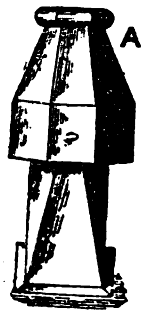
BANKRUPTS.

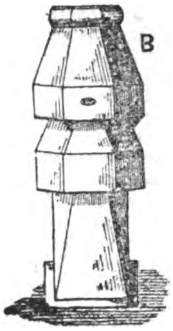
Cornelius Molony, of Tipperary, county Tipperary, builder.

John Killen, Malahide, and John Cunningham, Dalkey, County Dublin, trading in co-partnership as Killen and Cunningham, railway contractors, to surrender 8th and 29th January.

WE occasionally receive complaints from our town subscribers and advertisers relative to the non-delivery of the DUBLIN BUILDER, and as far as possible in each individual case try to rectify the error, and bring the blame home to the proper party. We must, however, remark, that in the majority of instances the fault lies at the doors of the complainants, and not with us or our *employees*, inasmuch as that frequently the journal *is* duly delivered either in letter-boxes or otherwise, and nevertheless does *not* reach the party intended. Why? it is not *our* business, but that of our *patrons*, to investigate.

HAGAN'S PATENT VENTILATING CHIMNEY-TOPS





Will cure smoky Chimneys, whether their position be under high buildings, or in the most exposed situations. They preclude the necessity of building tall chimney-shafts, or using long tubes; and they do not admit rain, or the smoke of other flues. They cause an upward current, and (their vertical stays, &c.) effectually prevent down draughts. They have no moveable parts; are silent in their operation; cannot get out of repair; and can be swept by the chimney-sweepers' machines.

1st Size (for ordinary fireplaces).... A. 30s.—B. 35s. each.
2nd „ (for small kitchens, &c.) .. A. 33s.—B. 38s. „
3rd „ (for large kitchens, &c.) .. A. 36s.—B. 42s. „

The double-head Tops B are invaluable for short flues, and very exposed situations.

Manufactured (of Strong Zinc, No. 13 Guage) and sold by H. W. GATES, 67, Westminster-bridge Road, Lambeth.

TERMS, CASH.

P.S.—The lower portion can be made any form and size, to suit any flue or fit on any chimney-pot or tube.

N.B.—If parties find any delay in the execution of their orders, they are requested to communicate with the Patentee, CHARLES HAGAN, Tower of London.

AND SUNDRY PRIVATE DWELLINGS.

Oils, Colours, Glass, &c.

MANNIN'S Wholesale and Retail DRUG, OIL, COLOUR, and GLASS WAREHOUSE,
2, GREAT BRUNSWICK-STREET.
(near D'Olier-street.)

Cattle Medicine of all kinds.

N.B.—Every article is warranted genuine, and at the lowest price.

PROPAGATING GLASSES, & GARDEN CAPS for covering Flowers. A large Stock at JOHN CARRICK'S, 5, MARY'S-ABBEY.

UNION PLATE GLASS COMPANY.

The very beautiful article of Plate Glass, manufactured by this company, can be had at the price of the lowest in the market, shipped to any Port in Ireland.

H. SIBTHORPE AND SON,
Agents for Ireland,
11 AND 12, CORK-HILL, DUBLIN.

TABLE GLASS, BOHEMIAN GLASS, PARIAN VASES, FIGURES, & HYACINTH GLASSES.
JOHN CARRICK, 5, MARY'S-ABBEY.

ROOM PAPER, in great variety, at MAURICE BROOKS', SACKVILLE-PLACE, Dublin.

GLASS SHADES—ROUND, OVAL, and SQUARE, with Gilt, Black, and Inlaid Stands.
JOHN CARRICK, 5, MARY'S-ABBEY.

JOSEPH O'LEARY, DECORATOR, Painter, Room Paper Manufacturer, and Dealer in Window Glass, and Laminated Lead for Damp Walls, No. 1, TEMPLE-LANE, Dame-street.

GREENHOUSE GLASS.

GENTLEMEN requiring GLASS for GREENHOUSES will be supplied, on the CHEAPEST terms, at P. G. DUNNE'S GLASS WAREHOUSE, 112, MIDDLE ABBEY-STREET, DUBLIN.

Plate Glass (best quality) sold at a proportionately cheap rate.

PLATE GLASS kept in Stock and supplied immediately, whereby the usual delay in ordering from the Manufactory is avoided.
MAURICE BROOKS, SACKVILLE-PLACE, DUBLIN.

WINDOW GLASS—CROWN, SHEET, PLATE, POLISHED, AND ROUGH.
JOHN CARRICK, 5, MARY'S-ABBEY.

PLATE GLASS, PIER AND CHIMNEY GLASSES, of the largest dimensions, SILVERED; and all sizes, SILVERED and UNSILVERED, for mirrors, sashes, and shop fronts.

WALTER BURKE,
91 AND 93, MIDDLE ABBEY-STREET.

MANCHESTER STAINED GLASS WORKS, NEW WAKEFIELD-STREET, OXFORD-STREET, near the BRIDGE.—Messrs. R. B. EDMUNDSON and SON respectfully inform their friends that they have erected, and are now in the occupation of, extensive premises, adequate to the requirements of their rapidly-increasing business. In offering their acknowledgments to the public for the support extended to them since their establishment in Manchester (five years ago), Messrs. Edmundson and Son assure their patrons that in increasing their facilities for business, they have secured such claim to an increased support as the employment of the highest talent in design and execution of their work entitle them.

Messrs. E. and SON feel confident that their long experience (upwards of thirty years) and earnest application to the study of Ecclesiastical design, as seen in the many windows they have executed, will be received as a pledge for the correctness of their work in this branch of art; and the fact of their being the originators of the application of permanent ornament to rough and polished plates of the largest dimensions, and the imitation of statues on polished plate-glass, render it unnecessary to refer to their success in that very pleasing branch of artistic decoration.

In conclusion, Messrs. E. and SON beg to state, that in everything entrusted to their care the strictest attention will be given to propriety of design, with that economy which they flatter themselves will lead to the still more extensive introduction of Stained Glass, both in ecclesiastical and domestic buildings.

Messrs. E. and SON beg to call attention to the Illuminated Commandments, &c., by their new process, on Plate; also to their Monumental Brasses &c.

ROBERT MACLAREN & CO., EGLINTON FOUNDRY, GLASGOW,
Manufacturers of all sizes of CAST-IRON MAIN PIPES, for Gas or Water, by an IMPROVED PATENT.
GENERAL IRON FOUNDERS, GAS ENGINEERS and WROUGHT-IRON TUBE MAKERS.

THE ARCHITECTURAL MUSEUM.
SOUTH KENSINGTON MUSEUM, W.
PATRON—H. R. H. The Prince Consort.
PRESIDENT—A. J. B. Beresford-Hope, Esq.

THE following LECTURES and MEETINGS will take place in the Theatre of the South Kensington Museum on Wednesdays:—

Jan. 9. A Plea for Polychromy. By W. White, Esq.
Jan. 23. On the Art of Engraving (illustrating the several styles) and printing Plates. By S. C. Hall, Esq., F.S.A.
Feb. 6. The Four Sisters; or some notes on the Relationship of the Fine Arts. By John Bell, Esq.
Feb. 20. On the Architectural Antiquities of Guildhall. By Thomas Lott, Esq., F.S.A.
Mar. 6. Distribution of Prizes to Artist-Workmen, and Conversazione.
Mar. 20. An Architectural Journey in Aquitaine. By E. A. Freeman, Esq., M.A.
April 3. On the Architecture of the Eleventh Century. By J. H. Parker, Esq., F.S.A.

Cards will be sent to Subscribers.

GEO. GILBERT SCOTT, Treasurer.
JOSEPH CLARKE, Hon. Sec.
13, Stratford-place, W., where letters should be sent.

ART UNION OF IRELAND.—
THIRD YEAR.

The System of MONEY PRIZES, with the right of Selection in every case by the Prizeholder.

SUBSCRIPTION—ONE GUINEA EACH SHARE.

One Chance in the Annual Distribution for each Guinea subscribed.

The next Distribution in April, 1861.

PRESIDENT—The Earl of Charlemont.

TRUSTEES—The Right Hon. Maziere Brady, Lord Chancellor; John Barton, Esq.; and the Hon. Judge Berwick.

The Committee desire particularly to impress the importance of early Subscription through the Society's Agents, or direct to the Secretary, with a view to securing good Exhibitions in Spring.

GEORGE F. MULVANY, Sec.

Copies of the Annual Reports to be had at the Offices, No. 113, Grafton-street, Dublin, or sent free by post.

Building Ground, &c.

BUILDING GROUND.

TO BE LET FOR BUILDING, on NORTHUMBERLAND ROAD and the other NEW ROADS going from Upper Leeson-street to Mountpleasant-square, Upper Charlemont-street, and the neighbourhood of Leeson Park. The contiguity to the city, and salubrity of situation, makes this neighbourhood particularly adapted for the outlay of capital. There are several first class houses now erecting on these lands, together with the Church and Asylum for Blind Females (Molyneux Asylum).

The particulars may be known on application to the Offices, No. 15 Molesworth-street, Dublin.

BUILDING GROUND.

TO BE LET IN LOTS FOR BUILDING, the Ground on the North, South, and East sides of WELLINGTON-SQUARE, going from Leeson-street to Harcourt-street; also the ground opposite the Railway Terminus in HARCOURT-STREET.

The particulars may be known on application to the Offices of John Louch, Esq., Architect and Surveyor, 15, Molesworth-street.

BUILDING GROUND.

TO BE LET FOR BUILDING, on GARVILLE AVENUE GARVILLE ROAD, and FRANKFORT ROAD, RATHGAR, particulars of which may be known at the Offices, 15, Molesworth-street.

BUILDING GROUND NEAR SHANKILL STATION.—The Domvile Estate Act having lately passed the Legislature, Sir Charles Domvile is now prepared to offer to the Public a number of most desirable Sites for Building on his SHANKILL ESTATE, which immediately adjoins the Shankill Station of the Dublin and Wicklow Railway. This property commands the most beautiful views of the Bay of Shanganagh and of the Wicklow Mountains, and has abundant supplies of the best building stone and purest spring water. The Lands have been laid out so as to afford convenient Plots for Building, and long building leases can be given. Plans of the Lands can be seen and every information afforded by Messrs. Stewarts and Kincaid, Agents, No. 6, Leinster-st.; or by Randal Peyton, Esq., Solicitor, No. 83, Middle Abbey-street.

TO BUILDERS.—TO BE LET, in RATHGAR, on the Roundtown road, about 500 Feet of BUILDING GROUND, 260 feet from front to rere, at 4s. per foot. Also, in Rathgar-avenue and Beauchamp-avenue, 2,000 feet at 3s. per foot. Lease 999 years. The situation is unquestionably the best in the suburbs of Dublin. Apply to Dr. BEAUCHAMP, 115, BAGGOT-STREET; or to F ARMSTRONG, Builder, BAGGOT-STREET.

The Dublin Builder.

VOL. III.—No. 26.

TENDERS FOR WORKS.

THE time occupied by builders, or possibly the expense incurred for surveyors to make out estimates for intended works, is a subject which demands, from its importance to the well-being of the building interests, some consideration at our hands. In a former No. of this paper we alluded to it, but perhaps not sufficiently *in extenso* as it requires. Take up an estimate for a building of any note, and if at all carefully prepared, look at the labour—the infinity of labour—of production! Except money, there is nothing of more importance to the builder than his time; and if this latter is not at his command, the former must be in requisition to enable him to give in a correct tender.

A party intending to build, and who has approved of his architect's plan, commissions the latter to apply for tenders for the works. This is either done by public advertisement, or by invitation to a few selected parties, which latter is called limited competition. Generally speaking, in either case when the tenders are opened they differ considerably, but in the former, to an amount which is scarcely credible. A client of ours once remarked upon an occasion of this kind—"that some of these men must be either totally ignorant of one of the main qualifications for their art, or be utterly reckless of consequences." And why is all this? Because the time which should be occupied, or the expense which should be incurred in bringing out a correct bill of quantities cannot, in many instances, be afforded, and in other cases is not considered worth the chances of success. Therefore, a shorter and much less expensive method is resorted to, combining in a great measure guess-work with measurement in the cube. In some instances this mode is followed *pro tem.* by builders who have no anxiety to obtain the work, and with them produces the high estimate; well knowing from the number in competition, and the repute of at least one of the competitors, that they have no possible hope of success, but not wishing to decline their patron's well-meant introduction, they arrive at an amount which in their minds is a fair approach to the cost rather above than under, others of a more reckless and imprudent turn, chance the matter upon a minimum guess, never bestowing even a thought on quantities, because Mr. So-and-so, who has a direct interest in the plans being carried out, has told them the building can be erected for so much, citing as an example Slapdash, who built an exactly similar house for the same money, but neglecting to tell that he was bankrupt a few months after, and forgetting altogether he has become chronically attached to a habit of meeting his creditors occasionally. We have heard of a builder whose practice was, merely to look over the plans, see the ground, step it, and give in his tender. How these two latter modes terminate we can well imagine.

When it is taken into account the number of estimates a builder is obliged to furnish upon the most remote chance of success (we say obliged, because no matter how fully he may be employed, if he has connexion he cannot in all cases decline without giving offence to those who are anxious to serve him)—so many, that in a respectable builder's establishment with large practice, and where the proprietor is really anxious to give in correct tenders, one, or possibly two, clerks are constantly employed in this branch of the office business—we cannot wonder where the labour and expense is so great, and the chances in favour of a fairly priced tender so small, that less scrupulous parties will resort to the readiest and assuredly the most erroneous calculation; nor can it be a matter of surprise so wide a margin occurs between different tenders.

We are often astonished that parties intending to build do not sometimes consider the risk they run by employing the author of the lowest tender; it may be, or it may not be the works are completed for the contracted sum, but it often occurs that a considerable amount of embarrassment to all parties is the consequence. During the past few years how many contracts have we witnessed unfulfilled? how many buildings have been completed by others than the original contractors? Ranges of houses and suburban terraces have been left in every stage of completion, to the serious and incalculable loss of the proprietors, and the infinite annoyance of the architect.

Can we devise a remedy for this? we think we can. Firstly, surveyors' charges are too high, and act as a prohibition to their employment. We have known the charge for a bill of quantities amount to one quarter as much as the architect's entire percentage for plans, superintendence, and all. Let them be reduced, and a vast increase of business will be the consequence, which in the end will return them much larger incomes than at present. Secondly, let architects and the public set themselves fairly and with a will against the lowest tender, no matter how plausible, unless unquestionable security be offered for its fulfilment, and by a competent builder. Can proprietors conscientiously consent to the erection of their buildings by the timber merchant, the brick maker, the ironmonger, or any of the numerous wholesale merchants in connexion with building? we think not. Thirdly, let there be in all cases of competition for building of any magnitude, correct bills of quantities prepared by experienced and well known surveyors. Let each party in competition get a printed copy (we say printed in order to remove all charges of favour). Then the architect, if he knows his profession, and we assume he does, can easily discover—having a copy of the quantities—the *bona fide* builder.

With regard to the surveyor's charges, it becomes a matter of little moment, the successful party by previous understanding may defray them, or the proprietor, as may be arranged. In either cases we imagine it will amount to the same thing.

AFFILIATION OF THE INSTITUTE OF CIVIL ENGINEERS WITH THE UNIVERSITY OF DUBLIN.

AN arrangement has just been concluded—per favour of the Board of Alma Mater, actuated by a desire to include within its precincts a learned society worthy of the distinction—whereby the Institution of Civil Engineers in Ireland is admitted to the privilege of holding its meetings in the new lecture building, as also to the use of one of Professor Haughton's apartments for a library and meetings of council. A reciprocal courtesy is to be afforded by the Institute in the admission of the students of the engineering school to the meetings of the body, and access to their models. Doubly important advantages are thereby obtained, and we are pleased to learn that at the annual general meeting of the Institute on the 8th instant "a general concurrence in the propriety of the proposed measures" was manifested, and "a resolution passed giving the council plenary powers to carry out the necessary arrangements." On this occasion Sir Richard Griffith proposed the Earl of Rosse, Dr. Romney Robinson, and Professor Haughton, as honorary members, and the proposition was acceded to with acclamation. The ballot for officers for ensuing year resulted thus:—*President*—Sir R. Griffith, Bart. *Vice-Presidents*—Messrs. B. D. Gibbons, S. Downing, Charles Lanyon. *Council*—Messrs. W. Anderson, J. Bower, — Frith, R. A. Gray, J. Hill, R. Mallet, G. M. Millar, and Tarrant. *Honorary Secretaries*—Messrs. Tate and Stoney. *Auditors*—Messrs. Brazil and R. Harding. Messrs. Hemans and Mullins—as past presidents—to be *ex officio* members of council. *Treasurer*—Mr. Tate. Mr. Mullins, the out-going President, then addressed the meeting, observing that "he had the satisfaction of feeling that he had endeavoured to perform, at least, the duties which devolved upon him; that, with the assistance of the members of council, he had sought to give a new impetus to the future proceedings of the institution in the highly honourable affiliation now happily established with the University, and that he had delivered his trust into the distinguished hands of Sir Richard Griffith, who in again accepting the chair, after a long and laborious professional career, when others would have sought repose, gave convincing proof of his devotion to the interests of the institution."

Sir Richard Griffith, the newly-elected president, having been then duly moved to the chair, expressed himself as fully sensible of the favour conferred on him by electing him a second time to fill the chair of the institution; that when the office was recently offered to him, his first intention, owing to advancing years and much public occupation, was to decline the honour, but, being induced by the representations of the members of the council to believe that his acceptance would be desirable, he resolved to give this additional proof of the interest he took in the well-being of the society, and to devote to it all the time that his avocations would permit. He also stated that he had intended to deliver an address on the present state of civil engineering in Ireland, but that owing to the lateness of the hour to which the proceedings of the evening had been carried, he would defer it to the next meeting, which would be held in Trinity College.

A vote of thanks was then passed to Mr. Mullins, for the zeal at all times shown by him in promoting the interests of the institution, and more especially in maintaining its reputation during the period of his presidency.

ANCIENT ROADWAYS.

THE first steps towards the construction of permanent and durable roadways are said to have been taken by the Greeks, and also that this people expended considerable care and labour in their construction. But more noted than the Greeks in this matter, were the Carthaginians. from whom the Romans are by some reported to have derived their success in similar works. The first Roman road was constructed during the censorship of Appius Claudius, about 309, B.C.; it was first carried to Capua, and afterwards extended to Brundusium, a length of 350 miles; its breadth is about 14 feet, and its thickness, 3 feet; the paving being laid upon a foundation of rough stones cemented with mortar, and that again upon a bed of gravel. This road is still entire; it was called the Via Appia in honour of the consul, as was the second, the Via Aurelia, and the third the Via Flaminia. In the time of Julius Cæsar, the number of roads had greatly increased, so that all the principal cities of Italy were connected with Rome by paved roads, and from that period such means of communication began to be extended into the provinces, their principal object being to provide a ready mode of access into distant provinces, for the passage of troops and similar purposes. Augustus, when emperor, paid more attention to the great roads than he had done during his consulate. He conducted roads into the Alps; his plan was to continue them to the eastern and western extremities of Europe. He gave orders for making an infinite number in Spain; he enlarged and extended the Via Medina to Gades. At the same time, and through the same mountains, there were opened two roads to Lyons, one of them traversed the Tarentaise, and the other was made to the Alphenin. Agrippa seconded Augustus ably in this part of his government. It was at Lyons he began the extension of roads throughout all Gaul. There are four of them particularly remarkable for their length, and the difficulty of the country through which they passed. One traversed the mountains of Auvergne, and penetrated to the bottom of Aquetaine. Another was extended to the Rhine at the mouth of the Meuse, and followed the course of the river to the German Ocean; the third crossed Burgundy. Champagna, and Picardy, and ended at Boulogne-sur-mer; the fourth extended along the Rhone, entered the bottom of Languedoc, and terminated at Marseilles. From these principal roads, there were an infinite number of branch roads, namely, to Treves, Strasburg, Belgrade, &c. There were also great roads from the eastern provinces of Europe to Constantinople, and into Croatia, Hungary, Macedonia, and to the north of the Danube at Torres. The seas were able to cut across the roads undertaken by the Romans, but not to stop them. Witness Sicily, Corsica, Sardinia, England, Asia, Africa, the roads of which countries communicated with the roads of Europe by the nearest ports. What labours! when we embrace in one point of view, the extent and the difficulties which opposed themselves—the forests opened, the mountains cut through, the hills lowered, the valleys filled up, the marshes drained, and the bridges that were built.

"The Roman roads," says Mr. Tredgold, "ran nearly in direct lines; natural obstructions were removed or overcome by the effort of labour or art, whether they consisted of marshes, lakes, rivers, or mountains. In flat districts, the middle part of the road was raised into a terrace.

"In mountainous districts, the roads were alternately cut through mountains, and raised above the valleys, so as to preserve either a level line or a uniform inclination. They founded the road on piles, where the ground was not solid; and raised it by strong side-walls, or by arches and piers, where it was necessary to gain elevation. The paved part of the great military road was sixteen Roman feet wide, with two sideways, each eight feet wide, separated from the middle way by two raised paths of two feet each."

If we carefully trace the distance from the wall of Antoninus in (Britain) to Rome, and from thence to Jerusalem, it will be found that the great chain of communication from the north-west to the south-east of the empire, was drawn out to a length of 4,080 Roman miles, or 3,740 English miles; the public roads were accurately divided by milestones and ran in a direct line from one city to another, with very little respect for the obstacles either of nature or private property; mountains were passed, and bold arches were thrown over the broadest and most rapid streams. The middle part of the road was raised into a terrace, which commanded the adjacent country, and consisted of several strata of sand, gravel, and cement, and was paved with large stones, which in some places near the capital were of granite. It is estimated that the Romans constructed, in all, not less than 14,000 miles of paved roadway.

Since the Romans, no country seems to have surpassed or even equalled them in the hardness or durability of their roads. In England we may presume that this branch of engineering has been carried on with greater success of late years than in any other country of modern times; we say of late years, for it was not until the latter half of the eighteenth century, that any considerable improvement was effected; the roads previous to that period having been of a most rude and unsatisfactory description. The greater share of praise for improvement in the construction of roads, is due to Mr. Telford, the eminent engineer, who reduced the practice into a system conformable to the laws and requirements of science.

THE ANTIQUITY OF GOLD IN IRELAND.

DR. WILDE, in the second portion of his catalogue of the Museum of the Royal Irish Academy—noticed in present No.—prefaces the class of metallic material thus:—

"Did manufactured gold and stone weapons and tools co-exist? Our history is silent on this point, and as yet well-authenticated notices of the discovery of any such combination have not been recorded. It is, however, remarkable that the first historic notice of any metal in Ireland refers to gold; for under A.M. 3056, we read in the Annals of Clonmacnoise and those of the Four Masters, that in the reign of Tighearnmas 'gold was first smelted in Ireland, in Fotharta-Airthir-Liffe, or the territory of Fotharta, a woody district in Cualann, or Wicklow, to the east of the River Liffey,' and that the artificer's name was Ucadan. It is also stated by him 'goblets and brooches were first covered with gold and silver in Ireland;' but that would only prove the knowledge of gilding, either in the liquid form, or, what is more probable, by plates of gold laid over the article, such as we observe in counterfeit rings of great antiquity, and in some antique fibulæ which have come down to the present time. A similar application of gold may be seen in some of the Scandinavian breast-pins. It is, moreover, remarkable that most of the early forms of ornamentation, consisting of lozenge-shaped, chevron, zig-zag, or straight-lined patterns, together with, volutes, concentric circles, and spiral lines, found upon our earliest stone monuments, and clay urns of undoubted heathen origin, are also the forms of decorations chiefly observed in our earliest and simplest golden ornaments and bronze celts. Topographers have not yet determined the precise limits of the Fotharta Cualann, but it was undoubtedly near, and probably to the east of, the source of the Liffey. Upwards of three and thirty centuries elapsed without any further reference to native gold occurring in either our ancient annals or modern history; not even the most extravagant of the Finian romances, alluding to the existence of the metal in Ireland, although the authors decorated the heroes of these tales with oriental splendour. In the year 1796, however, in the same part of Wicklow—perhaps on the very site of the furnace of Ucadan—upwards of £10,000 worth of unwrought native gold was obtained in about two months, and small quantities have, from time to time, been gathered there ever since."

EMPLOYMENT OF IRON IN THE ARTS.

IRON is employed in the arts in three conditions:—First, in that of cast-iron; second, in that of wrought-iron; and third, in that of steel. The first and third of these substances consist of iron combined with carbon: in cast-iron with more than in steel. Wrought-iron is the metal nominally without combined carbon, but it is rarely obtained in practice so pure as to be absolutely devoid of a small proportion of carbon. When the molten stream of iron comes from the furnace, it is not in a state fit for the forger or the maker of steel. For this purpose it requires to be refined—that is, to have its carbon burnt away in a furnace called a finery, and still further, in the process technically called puddling. Intense heat and atmospheric air form the means by which the superfluous carbon is discharged, and the iron left in a comparatively pure state. The further progress of the metal is simple enough. It is submitted, while yet incandescent, to the operation of enormous hammers, which knead it into a tenacious mass. This is then taken to rolling-machines, which reduce it to the requisite size and shape, whether of bars or sheets. For the production of steel, a further series of processes becomes necessary. Cast-steel is produced by melting the bars of blistered steel in crucibles of fire-clay, and then pouring the fluid metal into ingot-moulds.

ARE CONTRACT PLANS THE PROPERTY OF ARCHITECT OR CLIENT?

THIS question—though previously discussed elsewhere in the abstract—is revived, to our minds, under *special* circumstances occurring within the last few days, and which have formed a subject for magisterial consideration. For obvious reasons we abstain from mention of names, at least in the present stage, though we shall probably hereafter have to report full particulars, should a further discussion be raised in a superior court, but which we trust the good judgment of parties concerned and their advisers will render unnecessary.

The facts are simply these:—Plaintiff avers that being—some six months since—about partly to rebuild certain business premises in this city, he sought the services of Mr. ——, an architect, and thereupon agreed with him, for a certain bulk sum, to furnish the requisite plans and specifications, reserving the right of employing him or not to superintend the execution of the work; but in the event of the former course being adopted, a further sum, equivalent to 2½ per cent. on the outlay, was to be paid. The plans and specification being prepared, tenders from contractors were called for by public advertisement, and one ultimately adopted. Plaintiff for some time (as alleged) remained in possession of the drawings, but the architect requiring them during his supervision of the work, became again possessed of them, and has since retained them. Owing to an unfortunate circumstance occurring during the progress of rebuilding, it became desirable that certain alterations and amendments should take place, thereby affecting the carrying out of the contract in its integrity. Business being resumed in the concerns, and the builder's duties ended, the architect sent in his account for fees, crediting thereon a sum previously received or sanctioned to be received by a third party. To this account the proprietor advanced no material objection, but the builder, in the interim of payment, sending in rather a *long* and unexpected bill for extra works—which plaintiff alleges the specification protected him from—withheld payment of the architect's account, pending inquiry; whereupon a *second* bill for an amount one-third greater, and including fees for "*drawing an agreement*," reading and checking the builder's bill of extras, and for commission thereon, was sent in by that gentleman. To this plaintiff demurred—being, however, still disposed to settle the *original* claim—as also to the builder's bill of extras, excepting a few items stated to have been *authorised.* Proceedings were instituted in a superior court, first by the architect for the *second* claim, and again by the builder for amount of *his* bill. The latter was referred to the Conductor of this Journal to advise upon, and comprised very numerous items. The premises were minutely inspected, and the statement of the plaintiff attentively considered; but, as will be readily understood, no decisive conclusion as to the legitimacy of charges for *extras* could be arrived at, in the absence of the plans and specification on which the contract had been framed. For permission even to *refer* to these documents, application was made to the defendant and his solicitor, but it was peremptorily refused—consequently summary proceedings were adopted in a police court. For our purpose it has been necessary so far to state the facts of the case, with a view of showing on what plea the plans, &c., were withheld from the client, and which our readers will at once comprehend was in consequence of the architect's *second* demand not being complied with; but we need not now enter into the details of the somewhat lengthened discussion at the head police office. It will, however, be desirable that our professional readers should know the decision of the learned magistrate on the question before him, and which was substantially to the following purport:—"That owing to the concurrent agreement for superintendence of the works, as also that the right of ownership had not been sufficiently established by actual possession and special payment for the plans and specification, and pending proceedings which had been commenced in a superior court, he should not feel himself justified in making an order for their delivery." But the learned magistrate suggested that the plaintiff should seek for a copy of the plans and specification, on payment to the architect of a proper sum, and in the event of refusal, that application, grounded on affidavit, representing the necessity of reference to the documents, might be moved in the court wherein proceedings were pending, and that access would then be compelled at the expense of the architect, who should be liable for costs.

With these particulars before us, we are introduced to the materiality of the question, viz., "was the architect justified in withholding access to the client or his authorised agent to these documents, sought to be referred to for the purpose of adjusting the builder's bill for works executed under his (the architect's) superintendence, the client not disputing the payment of *first* account—believed to be the true one—furnished for professional services?" According to our *own* doctrine we shall answer our *own* question with a decided negative, and when the readers of this journal shall have heard our reasons, we court rather than otherwise any opposite sentiments serving as they probably may to the solution of a somewhat vexed question.

According to the practice of the profession in Ireland it is the admitted duty of an architect engaged to design and carry out an intended work to furnish *two* sets of drawings and *two* copies of the specification,—the one a duplicate for the guidance of the contractor, and the other the *original* as signed by all parties concerned, determining the terms of the contract, and for office reference during the progress of the work, pending the winding up of all accounts in connection therewith. It *may* or *may not* be that a client should wish to consult the architect upon minor matters of detail, or upon requisite deviations during the execution of the work, and after the contract is fully signed, sealed, and delivered; but whether or not so, he has undertaken *to pay* for the plans and specification, he is assumed to be competent to do so—in the case in point it *is* so,—and he has the undoubted right whatever differences may arise between him and his architect to make use of same for legitimate purposes and in connection with the work to which they refer, until the final arrangement of accounts with both parties. An architect refusing his client such access, and thereby placing the latter in a position to *sustain damage*, fails in the fulfilment of his duty, and incurs a responsibility both in character and pecuniarily, only to be estimated by circumstances. Briefly, this is our reading of probable consequences, and they would be considerably aggravated if aught of vindictiveness intervened, and prompted a deviation from a recognised principle.

NATIVE SKILLED LABOUR.

IN an article under this title the *Freeman* says:—"Scarcely a week passes over that we are not called upon to direct public attention to the growing prosperity of native industry, skilled labour, or art manufacture. A locality, known as the South Liberties of the city of Dublin, bears about it unmistakeable evidences of its having been at one time the scene of busy thrifts and commercial opulence; the stranger passing through it now-a-days is struck with the fine old cumbrous, well-fashioned houses with stone facings, big and roomy staircases, narrow windowed, with the old Queen Anne gables with granite facings and stone mullioned doorways, each house costing as much as would now be required to build a terrace. The 'South Liberty' of Dublin was once a place in which the manufacture of cloth, silk, and poplin, was indigenous. Of late years a number of attempts have been made to manufacture tabinet and poplin in other countries, even France, where the looms of Lyons were not thought unworthily employed in trying to rival the poor 'Liberty Weavers.' Since then the Queen has repeatedly directed that this fabric should be furnished to her in large quantities. The courts of Petersburg, Berlin, Vienna, Munich, Dresden, and even Christiana, have made arrangements with their consuls that Dublin tabinets shall be forwarded to them as required. So extensive is the export trade at present of tabinet, poplin, and tabouret, that in the South Liberties, to which we have already referred, busy life is again presenting itself. The loom and shuttle are again beginning to make 'healthful music' in the establishments of our Lord Mayor (Atkinson), Messrs. W. Fry and Co., Messrs. Pim Brothers, Messrs. Dunne, O'Reilly, and Co; John Judge, Wm. Geoghegan and Co., Robert D. Cordner and Co., Robert Mitchell and Co., and the other traders embarked in this department of native industry. The growing requirements of the trade demanded that wool should be dyed quickly and well, and a dye-house, which cost for its erection a sum approximating to £1,500, had to be built for Mr. Eustace, 8, Weaver's-square. The construction of this establishment in all its departments is admirable, and bears about it a healthy sign of commercial life and activity."

BIOGRAPHICAL SKETCH OF BONARROTTI MICHAEL ANGELO.

This celebrated painter, sculptor, and architect was born at Chinsi, in Tuscany, in the year 1474. His talents were so early developed, that he is figuratively said to have been *born a painter;* and his parents observing the turn of his genius, put him under the tuition of Dominico Ghirlandaio, whom he soon surpassed; for at the age of sixteen he executed some pieces rivalling even those of antiquity. Under the auspices of that great patron of the arts, Lorenzo di Medicis, he established an academy for painting and sculpture at Florence; which on account of the troubles of the house of Medici he afterwards removed to Bologna. At the age of twenty-nine, he was employed by Pope Julius II. to construct a grand mausoleum; but before it was finished, he returned to Florence in disgust, on account of some pecuniary matters. From Florence he would have gone to Constantinople, whither he had been invited by the grand signor, to build a bridge from that city to Pera, had he not been prevailed upon to return to Rome by Soderini, the gonfalonier, or holy standard-bearer. This officer recommended him to his brother Cardinal Soderini, who introduced him to the pope, at Bologna. Here he met with an envious competitor, in the person of Lazzri Bramante d'Urbino, who had been employed by the pope, and was unwilling to share his honours and profits with another. He endeavoured to excite a spirit of discontent in Bonarrotti, by insinuating that the pope was too much offended at his former conduct, to permit him to resume the building of the mausoleum; and to the pope he represented, that as Bonarrotti was a painter, he might be more advantageously employed in painting the arch of the Sextine chapel, at Rome, than in any other work. It should seem from this, that Bonarrotti had not yet displayed those talents as a painter, with which he afterwards fascinated the world; for it is certain that Bramante, considering him as a dangerous rival, meant nothing less than his complete disgrace. Bonarrotti, however, though contrary to his inclination, painted the arch, so much to the pope's satisfaction, that he was taken into greater favour than ever.

Pope Leo X. ordered him to make a design for the front of the church of St. Laurence, at Florence, for which also several other architects had given in drawings, but Bonarrotti's being preferred, he was sent to Florence to superintend the building; the vestry of which is reckoned among his best productions. In this city he also built the Medicean Library, the niches and staircase of which are of a very curious construction.

On the death of Sangallo, in 1546, the pope, Paul III. appointed Bonarrotti architect of St. Peter's, at Rome, an appointment which he at first declined; but being vested with unlimited powers for carrying on the work, he not only accepted it, but even refused any remuneration for his labours. Sangallo had left a model for finishing the building, which had cost 4184 Roman crowns, and occupied some years in making; according to which the edifice itself could not have been completed in fifty years and upwards. The first use Bonarrotti made of his extensive commission was to set this model aside; and in fifteen days he produced another, for the small cost of twenty-five crowns, by which he proposed to raise that venerable pile with far greater facility and expedition, and with more majestic grandeur, than the plans of any of his predecessors could have given it. The four great piers, by which the cupola was to be supported, had been erected by Bramante, but they were so very weak, that succeeding architects had found it necessary to strengthen them. Bonarrotti thinking them still insufficient for the purpose, he enlarged them to their present gigantic size, and contrived to leave voids, like wells, in them, probably for the purpose of keeping them dry. Similar vacuities he left in principal walls, through which he carried a winding staircase, so wide, and upon so gentle an ascent, that he was enabled to convey materials to the height of the level of the arches on beasts of burden. The great cornice over the arches differs from the common cornice, in having less projection and fewer members; and the imposts of the pilasters have a greater projection. In each of the two curved extremities of the transept, it had been intended by former architects to place eight tabernacles, or altars; but Bonarrotti reduced their number to three, and threw an arch over them, subdivided into a few well-proportioned compartments; and to prevent any alterations in his design by future architects, he built the whole so solid that it could not conveniently be changed. He lived, however, to see the building carried to the height of the tambour on which the cupola was to be laid, when, on account of his age, his friends urged him to frame a model of the dome, lest what he had already done should be spoiled by the incapacity or whim of a succeeding architect. With this request he complied, and formed one of clay, which he afterwards caused to be made of more durable materials, by Giovanni Farnese. This model was universally approved, and finally executed in the pontificate of Sextus V. Whilst Bonarrotti was engaged in the building of St. Peter's, the officers called *conservators*, in the time of Paul III. resolved to reduce the Capitol to an useful and convenient shape, for which purpose they applied to Bonarrotti. He accordingly began the Senators' Palace, in the centre, ascended from without by a double flight of steps; landing on a level introduced between the two flights. The wing, denominated the *Conservatorium*, is entirely from his design. The ground-floor consists of an external and an internal portico, supported by sixty-eight columns of the Ionic order, surmounted with that elegant capital, the invention of which is attributed to himself. There is, however, a great blemish in this part of the building; for, in order to give a due proportion to the width of the portico, the columns are niched into the wall, an expedient never productive of beautiful effect. About this time he also finished the Farnesian Palace, which had been begun by Sangallo. He likewise designed and executed the gate, called *Porta Pia*, the architecture of which is not very regular; of many other gates designed by him, it is uncertain whether any of them were ever constructed, but they are all of the same irregular taste. The great central hall of the Dioclesian baths was converted into a church from a design of his; as were the chapel of the Strozzi family, at Florence; and the college of the Sapienza, except the part where the church is situated; it is upon the whole a very fine edifice.

Old age having at length rendered this great architect incapable of personal exertions, Nanni Bigio was secretly commissioned by the pope to superintend the building of St. Peter's, but with strict orders to adhere minutely to the plans and model of Bonarrotti, who died in 1564, in his 90th year, before the dome was completed. His body was transported to Florence, by order of Comes de Medicis, where it received the most splendid funeral honours, and a superb mausoleum was erected to his memory, at the expense of the grand duke.

THE OPENING OF SAINT SAVIOUR'S CHURCH.

On this date the most elaborate and beautiful ecclesiastical structure as yet erected in this city, is being consecrated for Divine worship. We have so frequently described this building during its progress, that we should find it unnecessary now to repeat particulars as to dimensions, arrangement, &c., but the internal furnishings, the altar, reredos, &c., being of an uncommonly beautiful character, we quote the following from the *Freeman's Journal*, which is ever vigilant in recording progress in Art:—

"The altar and its embellishments are cut out of the purest Caen stone, and its frontal consists of a group of seven niches, with systematic arches, finely cut, and forming an arcade, each niche being occupied by a piece of sculpture. The figures are those of angels, bearing sacred symbols. The arches of the niches are trefoliated, and sustained on shafts of green Galway marbles, with carved foliated capitals and moulded bases. The spandrils formed by the arches on the top of the altar are carved into rich clusters of lilies, roses, grapes, and shamrocks. The "mensa," or table of the altar, is a slab of white marble, resting upon a cornice, the hollow of which is covered with white roses. The tabernacle has a resemblance to the great mediæval or 'Sacramental housen', in the churches of Louvain, Ulm, and Nuremberg. The lower part, or 'tabernacle proper,' is a square temple. The front is formed by a deeply receding Gothic arch, moulded and carved with delicate and appropriate ornaments, and resting on shafts of red Cork marble, with elaborately carved capitals, representing wheat and vine foliage. The door of the tabernacle is formed of beaten, engraved, and enamelled brass, inlaid with precious stones. A foliated cross fills up the centre of the door, and the angles are filled with the emblems of the four Evangelists. The 'tympanum' between the head of the door and the arch above described is carved, and represents the 'pelican feeding her young,' allegorical of the Eucharist. The cornice surrounding the top of the tabernacle is carved with rosebuds and other blossoms, and the spandrils between the cornice and the arch are filled in with carved figures of angels bearing censers. The canopy over the tabernacle consists of open Gothic arches, resting on polished marble shafts, the spandrills being filled in with rich carving, in keeping with the rest of the work. Above this rises a lofty 'Fleche,' consisting of light open stone work, cut into exquisite designs, and surrounded by more than twenty figures of angels in the act of adoration. The 'reredos' consists of an arcade of six arches, three on either side of the tabernacle, resting on marble shafts. The arches are covered with crocketed gables, and the spandrils over the arches are filled in with medallion heads of saints of the Dominican Order. The lower part of the reredos is carved on diaper containing *fleur de lis*. The choir for the fathers is placed behind the high altar, after the manner observed in the Church of Santa Maria Sopra Minerva, at Rome, and other churches of the Dominican Order in Italy. Around this choir, and immediately under the stained glass windows of the apse, runs a string course or cornice, carved into grapes and vine, and terminating with angels bearing chalices. The eastern windows of the apse are filled with stained glass; the centre windows contain the subject of our Lord's Transfiguration. The side windows contain the 'Presentation of the Blessed Virgin in the Temple,' and her Coronation in Heaven. The spaces between the principal paintings in these windows are filled with designs in mosaic of the most gorgeous colours. The semi-dome of the apse and ceiling over the sanctuary is divided into panels, and painted on a gold ground, containing medallions with representations of our blessed Lord in the various symbolical characters, such as the 'Good Shepherd,' 'the Vine,' 'the Sun of Justice,' 'the Light of the World,' &c., interspersed with monograms and symbols in rich profusion. The ceiling of the compartment of the nave next the sanctuary is decorated in brilliant colours in medallions, containing the dog and torch lilies and stars, &c., the symbols of St. Dominick, and monograms of his name. The rest of the ceiling of the nave is panelled in brilliant colours, and the bay of the ceiling over the organ gallery is ornamented in corresponding style, with harps, hautboys, and other musical instruments. The beautiful organ gallery, which was described on a recent occasion, is now completed. To give some idea of the extent of the stone carving in this noble church, it may be sufficient to say that there are 18 full-sized figures of saints of the Dominican Order forming the corbels of the chief supports of the main roof; 60 figures of angels bearing various appropriate symbols and scrolls, and 10 corbel brackets intended to support full-sized statues of the saints of Ireland. Each of those corbels is in itself a study, displaying the correct taste and skill of the artists. Besides these there are several hundred feet of string courses, and countless corbels and capitals of varied design. The side altar of the chapel at the end of the south aisle contains as a frontal a pieta in marble,—one of the latest works of the lamented Hogan. This is surrounded by a framework of Irish marbles. Amongst the many other beauties of this church is the ceiling of the Chapel of the Passion, at the right of the south aisle. This ceiling is painted on a crimson ground, and decorated with symbols of our Lord's Passion, in gold and rich colours. The entire floor of the nave and aisles is occupied by richly-carved and commodious seats, formed in style and decoration perfectly in keeping with the general design of the building. The floor beneath the benches is thickly and solidly boarded, whilst the commodious passages up the centre, in both nave and aisles, are inlaid with Minton's encaustic tiles. Provision is made for lighting the church for evening worship, by beautiful gas standards of brass, each standard containing a cluster of fifteen burners. The splendid organ gallery is destined to be occupied by a superb instrument now in course of construction at the factory of the Messrs. Telford, Stephen's-green, and likely to be ready for permanent erection early in May next. The case of this grand new organ will be constructed after the designs of the architect, Mr. J. J. M'Carthy, whose artistic repute would seem to have gained his *comble* in the triumph of tasteful conception evinced in the construction of this beautiful church."

⁂ In addition to the above, we may remark, that the altar and reredos are placed too far forward for proper effects, that the decorations of roofs and brass furniture are by Messrs. Hardman and Co., and the carvings by Mr. Lane—Mr. Greene immediately directing.

KILKENNY ARCHÆOLOGICAL SOCIETY.

WE note with much pleasure the progress of this most laudable society with each succeeding year. The eleventh annual meeting took place on 2nd inst., and amongst the new members elected were the Earl of Portsmouth, and Benjamin Lee Guinness, Esq., the latter proposed by Mr. R. R. Brash, architect, Cork, in the following terms:—

"I have been requested by Benjamin Lee Guinness, Esq., of College-green, Dublin, to propose him a member of the Kilkenny Archæological Society. I need scarcely remind you of the noble and praiseworthy example set by Mr. Guinness in his restoration of the venerable fabric of St. Patrick's Cathedral, Dublin, an act of both good taste and munificence, that I sincerely trust will find imitators. I feel bound to state for the information of your members that these restorations are carried on with the most anxious care to reproduce the ancient features of the edifice without any embellishments unauthorised by the existing remains. The works are executing in a most permanent and satisfactory manner. I mention these matters to reassure the minds of the members of our society who must naturally feel anxious on the subject from the absurd rumours circulated a short time since by uninformed parties."

After other preliminary business the report for 1860 was read, which announced that during the year 58 new members were elected; that in reviewing progress, the committee proudly point to the results of co-operation, nevertheless that but for the generous donations of a small minority of the members and life compositions, the six shilling subscriptions would have proved insufficient. Furthermore, that henceforward the meetings will be quarterly instead of bi-monthly, and the "Journal" published accordingly; also that a "special illustration fund" is proposed. Referring to the museum, the report states "it is the only provincial institution of the kind in Ireland, and must prove a credit to the county and city of Kilkenny if properly supported. An instance to the point is the purchase by the Royal Irish Academy of the unique "Kilkenny Brooch," which but for the existence of this society's museum, and the consequent attention directed to such remains, would have passed into the hands of some travelling dealer, or been sold in London. It is a distinguishing mark of the management, not alone of the museum, but of the society at large, that not one halfpenny of its funds is expended in salaries—all its officers being honorary."

"Your committee are glad to report that much has been done during last summer to remove obstructions which disfigured the noble architectural remains of Jerpoint Abbey, and secure their preservation. The wall which stretched across the nave of the church has been removed, thus throwing open the view from east to west. A portion of ground, including the site of the south side aisle of the nave, has been purchased from squatters, enabling the committee to take down the enclosing wall, built when the abbey was lately under repair, and to remove it further south, so as to rescue from desecration the entire site of the abbey church; about enough land remains over to supply, by its annual rent, compensation to the caretaker. The thanks of the society are due to James S. Blake, Esq., J.P., a member of the committee, for the judicious and careful manner in which he carried out these improvements."

After some conversation relative to financial arrangements, the announcement of some presentations, and the reading of some papers, the society adjourned to first Wednesday in April.

ADAPTATION OF ARCHITECTURAL STYLE TO PLACE AND SITE.

A PAPER on this subject was read recently by Mr. Cosmo Innes before the Architectural Institute of Scotland, from which we collect the following:—

"When I see the progress of Edinburgh, its extension on every side, the constant change, and, I admit, general improvement in the streets of our New Town, I cannot doubt that the day is at hand when we shall have some of the same energy, the same taste and wealth, directed to the restoration of our grand old High-street. Now, when that day comes, I am sure the architects of Scotland will be prepared to treat the enterprise in a worthy manner. Why should our gables not rise bold and steep as of old, with crow-steps, if you please, or with those rich embellishments that seem so peculiarly suitable to that style which we naturally seek for in the grand old cities of Flanders and Upper Germany, and which Mr. Burnett has taught us to find at Nuremberg? It is not only our tall gables that are capable of being made very effective and ornamental. Why should our architects (in towns at least) so carefully hide the roof of the house—send out the lady without her head-dress! In the modern streets of our city we have but two styles—the style of last century, where the eaves came over the wall, and dripped over it (unless a lead gutter saved the passengers' heads)—or our modern fashion, which runs up a poor architrave or bit of cornice, trying to veil the slates and the roof altogether. I confess a great love for our genuine old Scotch style, of a range of windows breaking the eaves, and surmounted, each with its little gable, affording the most appropriate position for sculptured or chiselled decorations. Besides these, there may be our national corner turrets, which, when well managed, enliven the outline of our upper storeys, without flying in the face of any style. But this is not all. These only provide for the lower stratum of the roof. I see no reason why the roof should not mount high above all these accompaniments, and bear with it tier after tier of dormers—as many as you choose—and end, if it suits the situation, in a coping of open work, of which I don't know the name: it is amazingly effective in Glammis. I am unwilling to detain you longer on this part of my subject, which has, I dare say, been fully considered by professional men, who have found some impediment, which I cannot divine, to imitating some of the beauties of Flemish and German town architecture. I have ventured to recommend what I think the true course for improving our street architecture. It is in some degree with art as with language. We try back to the fountain of our mother tongue, not that we may speak or write like Chaucer or Barbour, but to gather or fix in our minds the foundations of grammar and idiom, which give us the mastery over our language and enable us to wield it. So with architecture. We don't want to build houses like the fifteenth century, cold and dark, without the comforts and conveniences of refined life; but if there is there the germ of our peculiar and national style, and if (as I believe) that style is capable of adaptation to all our present wants, it is for the architect, in following out his noble profession, to develop it, to modify and elaborate it; ever keeping in mind the spirit which can be found in every honest work of genuine art."

ARBITRATIONS IN COURSE.

For some time past numerous members of the profession in Dublin have been engaged in adjusting disputed points between builders and their employers,—practically illustrating as regards architects a maxim which finds particular favour with the legal fraternity, viz., that "it is an ill wind that blows nobody good." Perhaps the most important was that relative to the new buildings at Mount Argos, which we learn is decided, but we abstain for the present from stating particulars, as they will probably be published *in extenso* shortly in the advertisement department of this journal. *In re* the recently erected Commercial Hall, in Grafton-street, there has also been a protracted series of sittings, but we are not apprised of any conclusion being arrived at yet. The cases of Meighan *v.* Baker, Bolton *v.* Tyrrell, Farrell *v.* Boulger, and Kelly *v.* Smiley have likewise been under consideration, and awards made, though hardly to mutual satisfaction; but with that we are not surprised, as litigants usually believe themselves right and their opponents eggregiously in error. Concerning the improvements in the locality of the Four Courts, several of our architects as well as professional valuators have been busy in arranging settlements with property owners in the neighbourhood, and in similar manner are proceedings going forward as regards the proposed Liffey Extension Line from the Broadstone to the North Wall.

FLAGGING THE FOOTWAYS OF TALBOT-STREET.

We learn that the footways at both sides of Talbot-street, between Gardiner-street and the railway terminus, are immediately to be laid with Caithness flagging. The cost (£416) is to be defrayed, one half by the property-owners and householders in the locality, and the other half by the Corporation. This will be the first introduction of the stone into Dublin, and we expect, judging from the specimens we have seen, that it will perfectly answer the intended purpose.

As an additional improvement in this important thoroughfare, we would suggest the removal (where practicable) of the projecting area railings on either side. Could this desirable end be accomplished now in connection with the flagging, there would be a fair width of pathway in this portion of the street.

MINING.

This branch of scientific and industrial operations seems to be gaining ground rapidly in Ireland, at least judging from the glowing reports of companies engaged, the remunerative dividends struck periodically, and the estimation in which mining shares are held in the market. Amongst the latest accounts are those of the Carysfort Company, which state, that the principal workings have been at Ballysillogue and Ballintemple; the sinking of the engine shaft was stopped at former place, and a level, at a depth of 25 fathoms, driven to cut the lode—the result being looked forward to with considerable interest. At the Ballintemple mine 25 tons of lead, of very superior quality, had been sold, and a similar quantity will be very shortly ready for sale. At Moneyteigue operations had been suspended. All the machinery, shafts, and levels are reported in first-rate order. The call in September last was promptly responded to by the holders of 14,000 shares, and £2,000 since lent on approved security.—

The directors of the Castleward United Company congratulate the proprietors on their favourable prospects, that operations are so far commenced as regards the building of an engine-house, putting up a steam-engine, with other machinery, laying pipes, &c., and that the present manager, Mr. Evan Hopkins, of London, had given a most satisfactory report as to the undertaking.

THE COUNTY SURVEYORSHIP OF KILKENNY.

Our readers have already been apprised, through other sources, of the vacancy that recently occurred in the surveyorship for this county, and of the particulars of the death of Mr. Samson Carter, C.E., who held that appointment for many years. We have now to announce with pleasure that Mr. Peter Burtchall, C.E., has succeeded to the office.

COUNTY SURVEYORSHIP OF WESTMEATH.

The situation of county surveyor for Westmeath has just become vacant by the decease of Florence Mahony, Esq., who has filled that important situation from the first appointment of county surveyor up to four o'clock on Wednesday, the 9th inst. The appointment is in the gift of the Lord Lieutenant, and the salary £300 per annum, with £50 allowance for clerk, and sundries for office, stationery, &c.

SLEEPING APARTMENTS IN RAILWAY CARRIAGES.

It seems to us somewhat strange that the directors of the main railway arteries in this kingdom do not provide sleeping accommodation for *night* and *invalid* travellers especially. Surely if our steamboats, which make the run across channel in 3½ hours, are fitted with berths for repose during that short period, a railway train, in which a considerably greater time is passed on long journeys, ought to have some similar accommodation? Our Midland Great Western *did* introduce *coupées* furnished with bedding —whether they are now in vogue or not we cannot say; but we would submit the question for the consideration especially of the London and North-western, the Great Northern, and Great Western Railway Companies of England respectively. Even a first-class carriage—luxurious as it is—nevertheless being usually divided into sitting compartments, does not admit of one enjoying *bon repos* recumbently; and what we would suggest is this, that to each train destined for a long journey, say over 100 miles, a separate carriage, arranged with a limited number of beds for males and females—as on shipboard—be provided, and we have no doubt that should the directors even consider themselves justified in making an *additional charge* for the extra comfort thus afforded, a large proportion of the public would gratefully appreciate it as a boon. If the London and North-western, for instance, would assume the initiative, we have no doubt the others would follow. Personally we have noticed painful instances of invalids prostrated after a rough passage—*even* in the new steamers— between Kingstown and Holyhead, being jostled about in a crowded carriage, and, interpreting their wishes by their countenances, we might assume that joyfully *any money* would be given for the luxury of *a bed*.

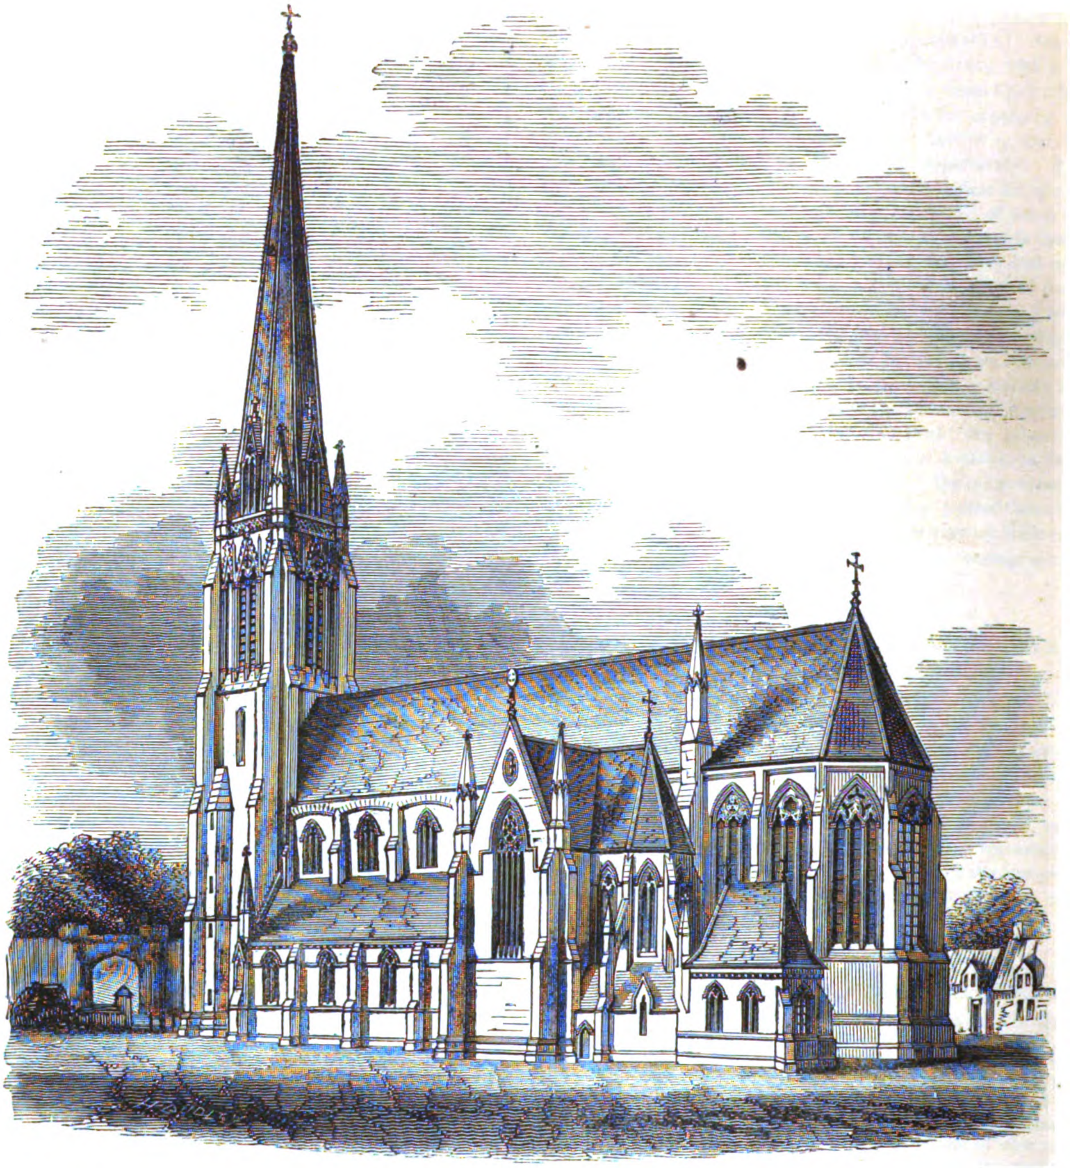
OPPOSITION OF THE RATHMINES COMMISSIONERS TO THE DUBLIN WATERWORKS BILL.

At a recent meeting of this body, it was resolved to give the most determined opposition to the bill proposed to be brought before Parliament next session, for the purpose of securing an improved supply of water to the city of Dublin, on the grounds of the Municipal Corporation having broken faith with the Commissioners. This resolution is very much to be regretted, but as at a special meeting of the Corporation on the 10th inst., Alderman Roe requested "the public to suspend their judgment on the subject for the present," we accept the suggestion, and trust that prior to next issue the matters in question will be adjusted.

NEW GRAND OPERA HOUSE IN PARIS.

For such of our readers as desire to enter the lists in this important competition, the following particulars (condensed from the general instructions which, with a map of the site, may be had at the Bureau des Batiments Civils, Paris) will serve as a preliminary guidance. *Designs* (only) comprising general plan, elevation of principal façade, longitudinal section, estimate and description, to be sent as above named before end of this month. Scale for plan, four millimetres, or 1 to 250; motto and sealed letter as usual. The successful competitor to have the carrying out of the work; the *second* in merit, 6,000 francs prize; the third, 4,000. The first is conditional that in an artistic and constructive point of view it is deemed suitable by the jury, who will consist of the Minister of State, of members of the architectural section of the Academy des beaux Arts, and of the Council General of Civil Construction. The site is 150 metres by 70, surrounded by les Rues de Rouen, de Lafayette Mocador, and part of la Rue des Mathurins; and adjoining the first-named and the Boulevard des Capucines is to be a Grand Hotel de la Paix, with 600 bedrooms. Amongst other requirements are the following:—covered porticos, vestibules, staircases easy of access, accommodation for police, military, and sanitary purposes; for audience from 1,800 to 2,000; Imperial box, with separate entrance; ditto for subscribers; stage for 400 persons, depth 105 feet, width 46 feet; performers' rooms, &c.

We regret to perceive that a destructive fire recently broke out on the premises of Messrs. Clarke and Co., Engineers and Patent Shutter Manufacturers, Gate-street, Lincoln's-inn Fields, London, and consumed a large amount of property.



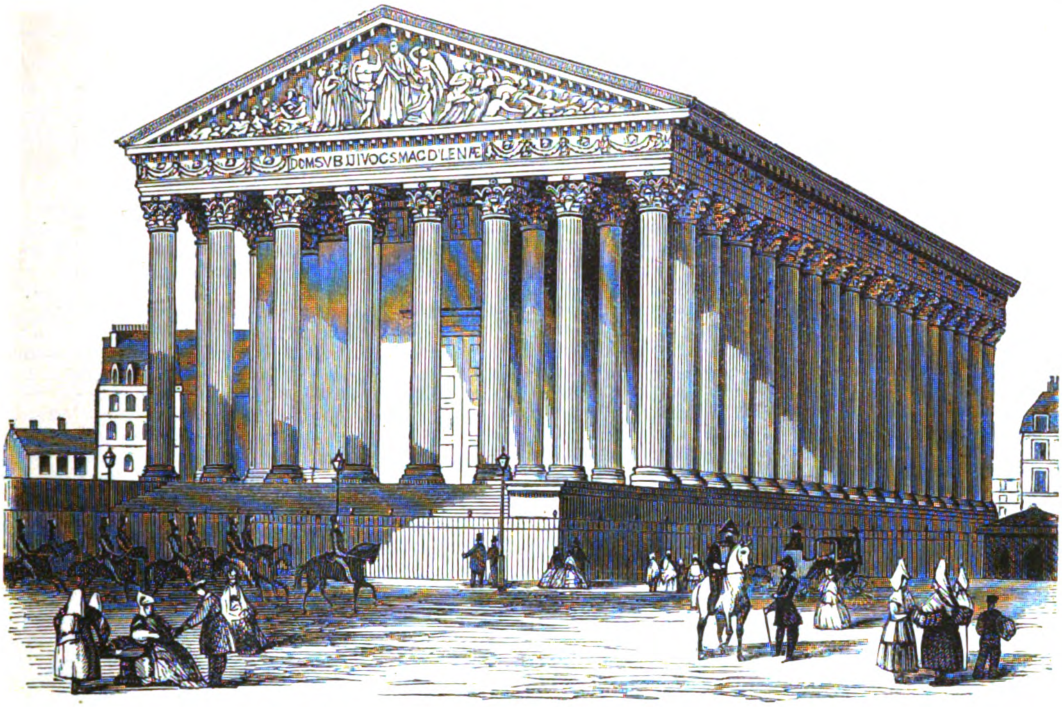
CHURCH OF THE IMMACULATE CONCEPTION, OXFORD.

CHURCH OF THE IMMACULATE CONCEPTION, OXFORD.

ONE of our illustrations in this No. comprises a view of a structure to be erected at Oxford, and dedicated as above named; and which, through the courtesy of the Rev. A. Comberbach, we are enabled to present to our readers. The building will comprise nave, aisles, transept, apsidal, chancel, sacristy, tower, baptistry, &c, and a site has been selected opposite to Christ Church College. The expenses of erection are proposed to be defrayed by subscription, of which the local Catholics have already contributed £500.*

---

* We are requested to mention that the expense of erecting this church is proposed to be defrayed by subscriptions, and that the Rev. Mr. Comberbach intends visiting this country with a view of seeking pecuniary aid.



CHURCH OF LA MADELEINE, PARIS.*

THE MADELEINE, PARIS.

In the middle of the eighteenth century, a church situated in the village of the Ville-l'Eveque being found greatly inadequate to the extent of the population of the neighbourhood, it was determined to demolish it and erect a new one in front of the rue Royale, in order that it might be a magnificent object from the Place Louis XV. The first stone was laid in 1764, and between that period and the revolution, the plan was several times changed, and the works suspended.

Bonaparte having formed the project of converting this building into a Temple of Glory, where the names of military heroes would have been inscribed on tablets of massive gold, the whole edifice was taken down, and the present one, in the form of a Roman Temple, was begun in 1806. The execution of this project was interrupted a few years after by political events. A royal ordinance of the year 1816, decreed that this edifice should be completed, in order to place in it expiatory monuments to Louis XVI. and his queen Louis XVII. and the Princess Elizabeth.

This church stands on an elevation, to which twenty-eight marble steps lead, is Greek in style, 328 feet long, and 138 broad. It is entirely surrounded by a colonnade of fifty columns, each 60 feet high, comprising base and capitals. Between each two columns is a niche filled with a statue of a saint. The portico fronts on a square which may be called the central or rallying point of not only the most interesting events of the past century of France, but of the present busy metropolis of Paris, the Place de la Concorde. It is supported by sixteen columns. These are surmounted by a tympanum, adorned with a bas-relief of "The Last Judgment," a bold and striking production. Mary is seen kneeling at the feet of the Sovereign Judge, imploring mercy for the fallen. The blessed are on the right; and allegorical figures of Faith, Hope, and Charity support Innocence. The immense doors are bronze, richly ornamented with subjects taken from the Old Testament; each door is 33 feet high and 16½ feet broad. The interior consists of a simple nave without aisles, and is literally dazzling. The walls, arches, columns, with the capitals and bases are all polished marble, gilded or richly painted. The ceiling is divided into three domes, which admit the only light. On the sides are recesses or side chapels, each containing a statue of the saint whose name it bears. The main altar is grand beyond expression. A marble group represents the once sinful but now repentant Mary, supported by three angels who are conducting her to heaven.

THE ADMIRAL MOORSOM.—The London and North Western Railway Company have placed on "the express" line between Kingstown and Holyhead, a fine steam vessel bearing this title. She measures 230 feet in length by 30 feet between paddles, has 400 (nominal) horse power, engines working at 1,200, and draws 10 feet of water. Her commander, Captain Hirste, to a certain extent superintended her construction, and she is said to be a first-rate sea boat.

THE DIPLOMA QUESTION.—The Royal Institute of British Architects fixed the 14th inst. for considering the resolutions agreed to by kindred societies, with reference to the diploma question, but as the debate was conducted with closed doors, we are unable to announce in this number either particulars or the decision arrived at.

The North Atlantic Telegraph is about being proceeded with, under the directions of Sir Charles Bright, C.E.

The Limerick and Castleconnell Railway has been assigned over to the Great Southern and Western.

The ceiling of the apartment in Conduit-street, wherein the Institute of British Architects is wont to assemble, has been quite destroyed by the thawed snow finding its way through the roof.

Sir John Watson Gordon, the distinguished President of the Royal Scottish Academy, has received her Majesty's commands to paint a portrait of the Prince of Wales.

It is proposed to erect, in the neighbourhood of St. Clement's Inn, Strand, London, a monster hotel. The clearing away of Holywell and Wych Streets will be thereby necessitated, and the widening of the Strand effected. Capital, £600,000.

Among the railway aplications for next session is one for a tubular underground line, of a mile and a half, from Regent's Circus, London, to the metropolitan line at Smithfield. Ultimately it is intended to extend the line from Regent's Circus to Kensington.

All the arrangements are declared to be perfect for having in London, in 1862, an International Exhibition on a scale still more imposing than that of 1851.

---

* In consequence of disappointment, we are obliged, at latest moment, to substitute this block for another in our engraver's hands, but which will be ready for next number.

ST. ANDREW'S CHURCH.

PRELIMINARIES for the rebuilding of this structure have occupied a lengthened period in arrangement, but they now seem to be arriving at a satisfactory termination, as we find that in the Consistorial Court, on the 10th instant, the Honorary Secretary, Mr. Acheson, T.C., declared "that the building committee had satisfied all the parties who had lodged objections, and that those objections had been withdrawn." The arrangement acceded to for this purpose is, "that the vaults in the churchyard should not be interfered with, that they should be permanently covered over, and that a license should be issued for the removal in coffins, in a proper manner, of the remains which would be interfered with to another part of the churchyard."

As regards the work of rebuilding, Mr. Acheson says, "that £10,000 would be required, of which they were to get £4,300 from the Ecclesiastical Commissioners, and they had now £3,800 themselves. Further, that it would seat 1,000 persons; that the building committee offered to give the city 20 feet of room from the old porch—which would considerably widen the street at that point—on condition that the Corporation would assist them in putting up an ornamental railing and stone work outside the church, which would cost between £400 and £500.

THE FIRE-ESCAPE MOVEMENT.

A MEETING was held on the 7th inst. in the vestry of St. Thomas' Parish, Mr. H. Coull in the chair. Mr. O. Spear moved and Mr. F. Carolan seconded a resolution to the effect that Mr. Robert Harper be authorized to collect supscriptions.

Dr. Shaw submitted suggestions as to making dormer windows, so as to afford the inhabitants a facile mode of egress and escape in case of fire. He also advocated the organization of a fire brigade.

The Chairman suggested that Dr. Shaw should submit his propositions before the meeting of the Life Protection Society, which would take place next day.

Several subscriptions were handed in, and

Mr. Scott read a letter from the editor of the DUBLIN BUILDER, accompanying a number of that periodical wherein the system of fire-escapes was advocated.

A fire-escape, designed by Mr. A. P. Allen, Co. Wexford, has been on view some time at the Commercial Buildings. It weighs but 20 lbs., and it is said that in it children or aged and infirm persons can be rescued with facility. The *Freeman*, in describing it, says—

"This apparatus is remarkable for originality of contrivance, simplicity of construction, and evident practicability of adaptation in cases of sudden emergency requiring its use. It comprises a light but solid hoop or circle, to which is affixed a stout fire-proof canvass *pouch* or *sack* distended, and having a strap inside to serve as a seat for the person or persons descending by it. This hoop is attached by shrouds of fire-proof cord to a single stout rope, also fire-proof. This rope runs through a block, fitted with a stout grappling hook, to attach it to a window sill or other convenient hold. Another rope, or 'down haul,' is affixed to the bottom of the sack, and thus, when the person escaping is securely seated within the hoop and sack, the 'down haul' rope is drawn outwards by the persons below, thus keeping the apparatus clear of flames from the lower windows, and the purchase-rope being eased away, the machine conveys its living freight safely to the ground. It can then be drawn up again by hauling on the purchase-rope, and thus many lives saved from otherwise inevitable destruction."

To *our* minds this contrivance is not "what it seems," nor is it suitable to the exigency of a *great* fire. The canvass *pouch* or *sack* referred to we would—perhaps inappropriately—term a *breeches*, similar to those on some recently invented life preservers, and presenting nothing whatever of novelty; and certainly on the *fire-proof* cord, the sole means of suspension and assistance to descend, we should place very slender confidence, with flames bursting out externally through every aperture. Moreover, the fixing of the pulley might be, under certain circumstances, a work of considerable *time* and *difficulty*, and if insecurely effected—as most probably it would in the hurry, confusion, and nervousness attendant on such an occasion—the wretched occupant flying from the fire would inevitably be dashed to atoms.

Messrs. Edmundson and Co., of this city, patentees of improved gas apparatus, have recently lighted in a most superior manner the residence of Sir C. C. Domville, at Santry.

THE *IRISH TIMES* AND ART IN IRELAND.

OUR contemporary, in an able resumé of national artistic matters—past, present, and to come—has the following; and we are pleased to see that a journal of such *locus standi*, and chiefly devoted to politics and the ordinary gossip of the day, can afford a leisure hour to *consider* and *chronicle* so comprehensively the position of our arts, which all must admit do not keep pace with the scientific progress of the age:—

"If in ancient times Ireland was the land of schools, it was also the land of artists. The elaborate carvings on many of our ancient crosses and monuments, the jewellery and workmanship of our torques and shrines, and the illuminations of our manuscripts, prove that a wide encouragement was given to art—grotesque, indeed strange, but fully able to bear comparison with anything produced by the English and Continental schools of the same era. In modern times due credit is not given to Ireland for the artistic genius she has produced. The catalogue of artists apparently belonging to the English schools presents many Irish names. The age of "Sir Joshua" derived some additional lustre from the genius of the unfortunate and eccentric Barry, who, perhaps, is best known to us through the biography of his kind and discriminating patron, the illustrious Edmund Burke. In our own day, Maclise and Danby, M'Dowell and Foley, are amongst the brightest ornaments of the so-called English schools of painting and sculpture. If, then, artistic talent be not rare amongst us—if it be true, as has been often said, that, owing probably to the predominance of the imaginative faculty, our countrymen possess a peculiar aptitude for art—how comes it that our schools are in so backward a condition, and that our public taste is comparatively so low?

"Does anyone suspect us of libelling our aristocracy or our *bureaucracy*, let him look at the edifices which have arisen of late years to disfigure the streets of a city whose architecture was once classical and chaste. Let him consider—and it will be with sorrow and chagrin for our still beautiful metropolis—what noble opportunities were thrown away when the *Barrack style* was adopted for the new buildings at the Four Courts, and for the Museum and National Gallery on Leinster Lawn. These were official Vandalisms, certainly, perpetrated by those whose notion of architecture for a great capital seems to consist in the piling together as much stone and mortar as can be got for a given sum of money. Did there prevail amongst us a more correct appreciation of the beautiful and dignified in art, such barbarism would not have been received with indifference, nor applauded as a triumph of economy."

Referring to the intended Exhibition of 1861 at the Royal Dublin Society House, the *Irish Times* says:—

"The Exhibition will be arranged in the new Agricultural Hall, in Kildare-street, a gallery being added to provide more abundant space. This building, lighted from the roof, and constructed mainly of iron, *seems* admirably adapted for the display, and for the safe preservation of pictures. An organ of suitable tone and power is to be erected, and we understand that occasional performances of music of a high order are contemplated by the society, so as to render the Exhibition entertaining and instructive to more than one sense."

We have already expressed *our* opinion on the preliminaries adopted for the project, and are not disposed now to repeat them.

GEOLOGICAL SOCIETY OF DUBLIN.

AT a general meeting of this society, which took place on the 9th inst., in the Museum Building, Trinity College.

The Rev. Professor HAUGHTON in the chair.

The Chairman stated that the society had been presented by Mr. T. Noble, of the Royal Artillery, with a specimen of a curious looking stone which was found in the Isle of Wight. The stone was formed like the barrel of a gun, and was evenly bored through its centre.

He believed it to have been formed by the percolation of water through a sandy bed, forming a sandy icicle as it were. The specimen was interesting from the very great evenness of its bore.

Mr. P. Ganly read a paper on the past intensity of sunlight as indicated by geological phenomena.

A discussion took place on the subject of the paper.

Professor Jukes having taken the chair,

The President read a paper "on the occurrence of ologoclase in the county Donegal," after which the meeting separated.

A provisional committee has been formed with a view of establishing steamboats after American fashion on Lough Erne, to commence plying next summer, and to make the double voyage, about 104 miles, each day five days in the week. The Dundalk, Enniskillen, and Derry Railway Company propose to connect their Enniskillen station, by means of a short tramway, with one of the points of embarkation.

THE RESTORATION OF ST. PATRICK'S.

IN the recent annual charge of the Very Rev. the Dean of St. Patrick's to the dignitaries of the church we find the following allusion to the cathedral itself:—

"On a former occasion, when I have drawn your attention to the venerable fabric of our cathedral, a tone of considerable despondency was of necessity to be traced in the report; for though enough was done in the renovation of the Chapter-house, and the restoration of the choir, to show the great capabilities of beauty in architecture which otherwise would soon have sunk under the crumbling hand of time; still, nevertheless, so much more remained to be done, that my allusions to the building at large were pronounced almost in a spirit hoping against hope. But I now have to tell you, for the honour of our city, that the Lord has raised up amongst us a man whose name will go down as a praise to the latest posterity. Blessed in his ample means, but more blessed in the largeness of his heart (for it is more blessed to give than to receive), Benjamin Lee Guinness, Esq., has energetically undertaken and greatly advanced in the general restoration of our time-honoured cathedral. Following the ancient alinements, the solidity of the work, and the fine taste in which it is executed, cannot be surpassed. The faithful purpose of this generous benefactor is not to seek the approval of man but the honor of God. And my difficulty is, in such a way to express, what I am sure is our common feeling of admiration, that while we speak the truth in the very highest approval, we should do so in a manner that may avoid giving pain to the simple piety of the author of such an unparalleled act of munificence."

THE VENTILATION OF HOSPITALS.

IN an excellent little pamphlet recently published under the title of "Hints on Ventilation," and reviewed in this journal, Mr. John Louch, architect, writes with reference to a plan for ventilating hospital wards:—

"Some time ago I was applied to to give an opinion as to the best mode of ventilating an hospital about to be erected. There were to be nine rooms on each floor, each about 36 feet by 23 feet, and 13 feet 6 inches high. The plan I recommended was, to have boxes made of strong smooth slate neatly put together; they were to be 9 inches by 4½ inches in the clear, with the two ends open, and to be as long as the thickness of the walls would admit of; the two ends to have fine perforated metal plates secured over them; the space inside to have six divisions of perforated zinc, or fly wire, properly secured across them. I should have mentioned that the rooms were lighted with two windows at one end, the fire place being at one side, and the door in the centre of the other end. I proposed placing four of these ventilators in the end, and as high up as the ceiling would admit of; that is, one over each of the windows, and one at the angles. I also had the upper lights of the windows made to open on pivots, but to be hung 3 inches up from the meeting rails; they would open at the top in, say 1 foot, and to have cranked iron bars secured to sash frames for the sashes when open to rest on; the space between the meeting rails would present openings of near 3 inches; and for the purpose of diffusing the air coming in, there should be fine perforated zinc secured to the lower sash meeting rail, the entire width of the sash. Gussets should be formed of plain zinc or wood on the sash frames, to fill the spaces at the sides formed when the upper sashes are open back on the cranked iron bars; these are to prevent the air blowing in on the inmates. I have some confidence in this plan, as I know the efficacy of fine perforated zinc being placed in the upper sashes of the windows, where one of the usual squares of glass is replaced with it, after an experiance of many years. Those acquainted with the beautiful principles of an instrument known as the respirator, will see at once the object I have for forming the ventilators as I describe; while an abundance of pure air will be at all times admitted into an apartment, all vitiated air will be effectually removed as fast as it is generated, and draughts perfectly prevented. Should these results be proved, the grand principle of hospital ventilation will be attained. I shall have great pleasure in showing the plans of various hospitals, and the mode of ventilation as adopted, to any person calling on me for this purpose."

PRESENTATION.

A meeting was held on the 20th ult. in the Society House, Dungannon for the purpose of presenting a testimonial and service of plate to Mr. Williamson, C.E., on the occasion of his promotion from the County Surveyorship of Tyrone to that of the county of Derry. The testimonial was most numerously signed, and the service cost £150, and was consequently exceedingly handsome.

A FAMILY ICE-HOUSE—HOW TO BUILD IT.

IT is interesting to see how some luxuries, long indulged, become necessities. With nine-tenths of our population, thirty years ago, ice was a luxury, both in city and country. Now it is an absolute necessity in our cities and large towns, and an exceeding convenience, if not a necessity, in our smaller villages and farm-houses—so much so that the ice-house is an important item of household economy. We need not discuss the purposes to which it may be applied. It is sufficient that the party interested know the fact, and we propose simply to tell him how to build it.

We have read any number of descriptions of ice-houses and how to construct them Some are built in a marvellous way—curious and intricate, deep in the ground, with under-drainage and compartments, costing a deal of money for no particularly good purpose. Others are plain as a smoke-house, built on the ground surface, and just as good, if not better, than the cellar ones. The truth is, the plainer the building, provided it be substantial, the better it is to preserve the ice, and that is all it is wanted for. We have built more than one ice-house, ourselves; have seen sundry of them built for others, and find that the simplest plan is usually the most efficient. The larger the house, the longer will the ice keep, as a rule, if well built, and a small house has, relatively, to be built with more care and thicker walls than the larger one, as the lesser quantity of ice contained in the small building is more influenced by the surrounding warm outside air than the other.

In the construction of family ice-houses, for ice purposes only, the builder is apt to make them too small. When ice-rooms are made inside of other buildings, and properly protected in the walls, its size is of less consequence; 10 or 12 feet square will answer a tolerable purpose; but the walls, floor, and roof should be thoroughly doubled and packed with sawdust or tan bark, as if it stood out of doors by itself. It is a very good way to build an ice apartment in a wood, carriage, or waggon house, if the space can be devoted to it; yet as the litter connected with the ice is frequently troublesome, and the moisture is apt to produce premature decay in the wood-work, where the whole structure is of wood, we would prefer that the ice-house be an independent affair of itself.

The building should be not less than 16 by 20 feet in area on the ground, and 8 or 10 feet high at the roof plates. That size is sufficient for the largest private family, unless ice is needed for extraordinary purposes, as in butter-making, &c. Take a lot of scantlings, 8 inches wide, 4 inches thick, and as long as the building is to be high. They should be of durable wood, as oak, pine, cedar, locust, black walnut or chestnut. Mark out the spot where the house is to stand, on the surface. Do not dig an inch into it, except to receive the feet of the scantlings, which are to serve as posts. For these dig holes 4 or 6 inches deep, that the foot of each can stand firm when planted. Set the posts 4 feet apart all around the area prescribed, which will take six on each side and five on each end. As they are set in, *stay* them together, and brace them from the ground at each corner by boards, so that they stand perpendicular and on a line. Then, inside of this enclosure, plant a second set of posts, 1 foot *in the clear* from the others. As this inner enclosure is 2 feet shorter and narrower than the outside one, the corner posts must be set a little nearer to the next ones than those on the outside, and stayed in their places in the same manner, or *cleated* temporarily, to them to hold them in place. Thus you have a double set of posts—a house within a house, or which is to be made one. When the posts are all in place, *plumbed* and *lined*, spike firmly and strong, on every set of posts, a common 3 by 4 inch scantling across the whole, from one side to the other, on the sides and even with the top of them—the latter being brought to a uniform height with the saw—so that the whole frame be fastened firmly together, like the outline of a huge box.

Now, take any kind of seasoned, straight-edged board, and line up both sets of posts on the *inner* side, or face to face, one board on each side only at a time, after the first 3 or 4 feet high are laid. Tack them on with small nails—for the filling will hold them fast in their places—and then pack in the sawdust or tan-bark between. Understand: the space between the boards is to be *flush*, and 10 inches apart in the clear, supposing the boards to be an inch thick, so that the posts will stand inside and outside the two linings, and make a full show both outside and inside the building, when completed. To make assurance doubly sure, and prevent a possibility of the posts spreading in the ground, at their feet, a set of floor-joists may be laid across, from inside to outside, and firmly spiked to each post; but in common cases this can hardly be necessary. In such cases, *gains* must be cut on the under sides of the lower tier of boards, or lining, to admit the joists and make a *close fit* of these boards to the ground. The lining of board being now 3 or 4 feet high, let the filling be thrown loosely in, and but gently pressed down, as hard packing will be likely to spring out the posts. As the filling progresses follow up with the boards till the top of the posts are reached, and the walls of the house are finished. At one end is to be left a door—we would have it in a corner. Of course it must be cased up on each side, like any door; no matter how roughly done, so that it is strong. We would have a partition across the inside, 3 or 4 feet from the inner row of posts, to accommodate an entrance room or closet for keeping fresh meats, milk, or other perishable articles in hot weather. This partition should be made by a single row of studs set in like those in the main building, and cribbed up on each side with boards, filling in between the cribbing and posts with sawdust or tan-bark, so as to admit no air, even from the closet, to the ice inside. Leave a door place, and hang a door in this partition, swinging outward, into the closet, so that the ice apartment may be kept tight always. Shelves, or any other conveniences may be put up in this ante-room, as may be preferred. The outer wall should have double doors—one opening out and the other inside—and fastened with a hook and staple. A rough plank or board floor can be laid over the surface of the ice room, a few inches of straw on that, and it is then ready to receive the ice. If the soil is clayey, very compact, so as not to absorb what water will probably drop from the melting ice during warm weather, a slight drain may be made underneath to conduct it outside, but stuffed with straw that no air can draw in and help to melt the ice. But in ordinary soils, their soakage will absorb the little water that will accumulate from the waste of the ice.

Now for the roof. Take common 3 by 4 scantling, and *gain* them on to the top of every outside part, at an angle not less than 30 degrees, or one-third *pitch*, and let them project full three feet down, outside, from the top of the posts, to give a thorough protection to the walls from rains that will fall upon it. Let the roof run lengthwise the building, and leave the entrance door of the house at the gable, or narrow end. The roof may be either of boards battened in two thicknesses over each other, or of boards and shingles in the usual way of house covering. A loose floor of common boards should be laid over the joints which cover the tops of the posts, and a loose coating of straw spread upon it. The gables may be nailed up with common boards, and small spaces left between them to give the loft within a free circulation of air; or, if made tight, a small slatted blind should be inserted, or a few augur holes made for the same purpose. Or, if a little ornament be desirable, a small ventilator, cupola fashion, may be built on the peak of the roof, with a 6-inch passage through the latter.

Thus, then, stands the ice-house, complete for use and the reception of 10 cords or 30 tuns of ice in a room, if the posts be 8 feet high in the clear, 14 feet square. If the ice be within a reasonable distance, the expense will not exceed a couple of dollars more to fill it than a smaller one; and not wanting so much, you need but half fill it; or, if filled, sell the surplus to your neighbours.

The building, when finished, will show the lines of post outside, which, in an outhouse, as this is, is no objection to its appearance. If so, the posts can be clapboarded, and any amount of finish given to the whole structure that is desirable. If left rough, as we would have it, without a plane mark about it, any coloured wash may be laid upon it to please the taste or fancy. Ours, that we built a year or two ago near our farm-house, we left rough and whitewashed. It cost us about 50 dollars, and we do not know of one that we would exchange it for, for our own purposes. It stands in a grove of trees, which are an excellent protection from the fierce rays of the sun, as well as giving it a picturesque appearance.—*The World.*

The Free Public Library at Liverpool, recently opened, had as many as 20,000 visitors per diem.

In the manufacturing districts of England there has recently been a quietude and depression, which Christmas period does *not* ameliorate.

It is proposed to place the town of Skibbereen under the provisions of the Towns Improvement Act.

It is believed, that the Emperor of the French is about to purchase up all the Railway Companies in France.

The Harbour Commissioners of Sligo are in favour of a connecting railway between Enniskillen and Sligo, by Manorhamilton and Blackburn, 38 miles, instead of that proposed by Lowtherstown and Bundoran, 64 miles.

Lord Caithness has appeared in London with his steam carriage, driving it through the most crowded thoroughfares with the ease and elegance of a *maitre de danse*.

EXPECTED NEW WORK.—A valuable lecture on church and conventual arrangements, recently delivered at the Royal Institute of British Architects, by the Rev. Mackenzie Walcott, is about to be published, with illustrations, by Messrs. Atchley and Co., Great Russell-street, London.

DIMENSIONS OF THE PRINCIPAL EUROPEAN CHURCHES.

THE Roman *Advertiser*, in an article compiled to shew the impossibility of St. Peter's, at Rome, being ever crowded, gives some curious statistics as to the comparative capacity of the most celebrated churches in Europe. We add a column showing the number of square yards:—

	Persons.	Sq. yds.
St. Peter's	54,000	13,500
Milan Cathedral	37,000	9.250
St. Paul's, at Rome	32,000	8,000
St. Paul's, at London	25,600	6,400
St. Petronio, at Bologna	24,400	6,100
Florence Cathedral	24,300	6,075
Antwerp Cathedral	24,000	6,000
St. Sophia's, Canstantinople	23,000	5,750
St. John Lateran	22,900	5,725
Notre Dame, at Paris	21,000	5,250
Pisa Cathedral	13,000	3,250
St. Stephen's, at Vienna	12,400	3,100
St. Dominic's, at Bologna	12,000	3,000
St. Peter's, at Bologna	11,400	2,850
Cathedral of Sienna	11,000	2.750
St. Mark's, Venice	7,000	1,750

The piazza of St. Peter's, in its widest limits, allowing 12 (persons) to the quadrate metre (square yards), holds 624,000; allowing four to the same, drawn up in military array, 208,000. In its narrower limits, not comprising the porticoes or the Piazza Rusticucci, 474,000 crowded, and 138,000 in military array, to the quadrate metre.

COURT OF BANKRUPTCY AND INSOLVENCY.

(Before Judge Lynch).

In re Killen and Cunningham.—These bankrupts had been contractors for public works, and the meeting was for proof of debts, surrender and appointment of assignee under the joint bankruptcy. The bankrupts formally surrendered, and Mr. Richard Martin, of the firm of John Martin and Son, North-wall, was appointed assignee. Agents—Messrs. D. and T. Fitzgerald.

In re John Kelly, of Ballymahon, builder, a bankrupt.—It appeared that the bankrupt had been dealing with the Messrs. Martin for three or four years, and they had furnished him with materials; that about twelve months since he began to get short in his payments, and in February following, on their application, he assigned to them as a security for their debt of £546, the profit then to accrue from a contract for the building of a church under the Ecclesiastical Commissioners, which he estimated at £400, and also £200 which he expected from another contract for flagging the town of Longford, and a policy of insurance for £500; the assignment was by a letter, and he undertook to execute a deed; he did not inform his other creditors of it, and the first intimation they got of it was its appearance in a "black list," which brought down his other creditors upon him. He was embarrassed at the time, but wanted to prevent Messrs. Martin from coming down upon him, in the hope that a good season might bring him through. A Mr. Longworth denied acceptance of a bill for £195, alleged to have been his; the signature was not his, and he did not know whose it was; he knew nothing about it until he received a letter in the bankruptcy matter. Mr. Martin appeared for the Messrs. Martin, and maintained their rights on foot of the assignment as an equitable mortgage. Judge Lynch said that after the evidence given in relation to the bill, and involving grave charges, he could not at present pass the final examination.

ASSIGNMENTS.—Hugh Francis Brophy, 10, Shamrock-villa, Co. Dublin, and Joseph O'Toole, of Mountain-view, Rathgar, Co. Dublin, builders and contractors, trading as Brophy and O'Toole, builders.

ARRANGEMENTS.—We learn that arrangements with creditors are pending in three cases, and are likely to be satisfactorily effected. In one instance especially there seems to be a strong feeling that it should be so.

WARMING STREET RAILWAY CARS. — An invention for warming street railway cars has been lately applied to cars on the railroad, says the *American Railway Review*. A furnace is attached underneath, on which are placed draft-doors, regulated by the motion of the car, so that there is certain to be a strong draft in either direction. Pipes extend from the drum of the furnace up through the floor of the car and along the whole length of the seats, from which sufficient heat radiates to warm the interior comfortably. These pipes are so adjusted as not to consume any of the space necessary for the convenience of passengers.

Scientific and Artistic Morceaux.

Mr. Robert Mallet, who has spent some years in experiments and investigations into the phenomena of earthquakes, completed them on November 23 by the explosion of six tons of powder in the hill at Holyhead from which stone is taken for the breakwater. The result favoured his wishes, for the mercury in the seismometer, or shock-measuring instrument, was seen to oscillate, though a mile and a-quarter distant from the focus of the shock. From this Mr. Mallet obtains data for comparison with observed natural shocks. Had he been at Copiapo on October 5, he might have felt and tested 116 shocks within twenty-four hours. The quarrymen at Holyhead reckon that for every pound of powder blasted, they should get on an average two and a-half tons of stone; hence the prodigious quantity that would be thrown down by a blast of six tons may be easily calculated. Prodigious though it be, the demand is so great for the breakwater, which has a width of 350 feet at the base, that within two weeks it may all be flung into the sea. We have heard that stone quarried in this way costs a fraction under ninepence a ton.—*Chambers' Journal.*

The Photographic Society have distributed among their members copies of a print representing a picturesque ruin in an effective style such as would be taken for wood engraving. But according to the epigraph, it is "absolutely untouched by the graver," and is a new achievement of photography, being, as we are informed, produced solely by the action of light. The inventor is Mr. Paul Pretsch: his process is as yet a secret; but so far as is known, it consists in taking an impression on a sheet of some glutinous preparation, from which an electrotype copper-plate is afterwards taken, and from this the picture is printed as from a wood-block. The result seems almost wonderful: anything that can be photographed is reproducible in the same way; hence there would appear to be no limit to the publication of copies of the best specimens of art.—Mr. Malone has repeated Niépce St. Victor's experiments on light, and concludes that the eminent French chemist has mistaken his results.—Mr. Mercer, of Accrington, has discovered a way of preparing calico for photographic impressions, which being dyed with a madder colour, are fast pictures that cannot be washed out. We have seen portraits thus produced which look as well as those on paper; and it may be that some ingenious persons will find in this discovery a new mode of marking linen, by photographing the owner's portrait thereon, instead of writing or working his initials. Possibly the ingenuity may extend to fancy waistcoat-patterns, in which faces shall be the chief attraction; and when a man can have his portrait large as life in the middle of his pocket-handkerchief, warranted not to wash out, the light-fingered professors will perhaps hesitate to try their skill on "wipes." Another discovery of Mr. Mercer's is worth notice: he dips calico in a certain kind of cold bath, whereby it undergoes a transformation somewhat similar to that of paper into parchment, and acquires a stiffness which no heat will afterwards soften. What will "outfitters" say to this?—a material for collars and wristbands which will not become limp!—*Ibid.*

In a former *Month* we called attention to Dr. Stenhouse's application of charcoal as a material for respirators, and as a disinfectant, an application which time and experience have abundantly verified. Many of our readers know that the ventilation of sewers is a question which has long been discussed and never brought to a satisfactory conclusion; they know also that the numerous gratings by which sewer-gases escape and rise into the streets are offensive and obnoxious to health, especially in narrow streets and crowded neighbourhoods. This is an acknowledged evil, but the sewers must be ventilated, and the more their contents are oxidised by admission of air, the more harmless do they become. As the openings must not be closed, and ought indeed to be multiplied, it occurred to one of the sanitary officers in the city to adopt the principle of Dr. Stenhouse's charcoal respirator, and having fitted a series of charcoal filters into the openings that lead from the sewers to the surface of the streets, he finds the solution of the important question, for the noxious gases are completely neutralised. Of course, special precautions have to be taken in the preparation of the shafts, and the filters must be kept dry, or the charcoal will cease to act, but of the result there is no doubt: the unpleasant smell is entirely destroyed. During the past two years, many parts of London, within the city, have been thus purified. The openings need not necessarily be in roadways, they may be led up through the lamp-pillars, or between party-walls, or into chimneys. A west-end engineer has tried the same plan in parts of Westminster, and with the like success; it is adopted in the new sewage-works at West Ham; it has been applied at Bowood, the seat of Lord Lansdowne, and we hear talk of its introduction into Glasgow. Its general adoption can only be a question of time, for charcoal is the cheapest remedy yet thought of for the prevalent evil; it is applicable at outfalls as well as along the course of sewers, and if kept dry retains its efficacy for many years. London, with its hundreds of miles of sewers, would require 25,000 filters.—*Ibid.*

Professors Bunsen and Kirchoff, of Heidelberg, to whom modern chemistry is largely indebted, have lately made a discovery which, in the vast field it opens for further research, may be ranked as the most famous of the year. It is a method of chemical analysis by means of spectrum. Most readers know that by spectrum is meant the rainbow beam reflected from a glass prism exposed to sunlight: it is producible also by the light of a lamp, and chemists and opticians have at times experimented on the changes that appear when different substances are burned within the lamp-flame. For delicate observations, it is essential that the spectrum be not too bright; much less bright, in fact, than that thrown by the solar beam; and Bunsen's lamp, which, burning hydrogen gas, gives a feeble illumination with great heat, is the best for the purpose. Now let us imagine the apparatus prepared, and the spectrum thrown into a box from which daylight is excluded. The professors above mentioned take less than a grain of chlorate of sodium, mix it with a small portion of milk-sugar, and burn it in the corner of their laboratory furthest from the lamp. An eye keeps watch on the inside of the box, and presently when the vapour has diffused itself, and meets the flame, a bright yellow line is seen to cross the spectrum, and remain visible for some minutes. This is called the sodium line, for whenever sodium is present in the atmosphere of the lamp-flame, and however combined with other substances, that particular line never fails to appear, even if the quantity of sodium be not more than one-twenty-millionth of a grain. It is found that each metallic base and metallic earth has its own peculiar line or lines: lithium shows a faint yellow and sharp red line; potassium, a red and a violet; strontium, four lines – two red, one orange, one blue; calcium, a green and an orange line; barium, more than a dozen lines, which may be described as one-half green, the other orange. And as with the sodium, each substance is always recognisable by its own peculiar line or lines, however infinitesimal the quantity tested. In fact, it would appear that even the ultimate atom could hardly escape this mode of analysis.—*Ibid.*

While carrying on their experiments, the professors noticed certain lines on the spectrum for which they could not account, produced by none of the substances enumerated above, but by some substances to them unknown. Considering hereupon, they ventured to assert that there existed in nature a fourth alkaline metal hitherto undiscovered. If they predicted its discovery, their prediction has been recently verified—as was that of the astronomers who predicted the discovery of Neptune—and they now announce they *have* discovered the new substance in notable though minute quantity, and they propose for it the name of spectrium. Judging from present appearances, Nature has not been lavish of this remarkable metal, for they had to operate on 800 hundredweights of the water of a mineral spring (the mother-water), to get—only fifty grains.—*Ibid.*

The French Engineers have availed themselves in the construction of the great breakwaters at Cherbourg of the faculty of the mussel fish—which attaches itself to piers with a material resembling coarse silk, enabling them to resist the force of the most powerful waves—and on large masses of stone they plant several tons of this shell-fish.

Bois durree, *or hardened wood,* which has been properly described as wood softened and then hardened, is made from sawdust, which under the influence of a high temperature and the enormous pressure of 600 tons, acquires a hardness a good deal exceeding that of wood. It is of a very fine grain, and fears no atmospherical variation; but its principal merit is its adaptation to moulding, and by the most economical processes forms and impressions are given which would require, in any other way, considerable labour and workmanship. We have seen various articles of great beauty manufactured from it, such as writing desks, inkstands, seal handles, medallions of royal and public characters, and even binding for books; on these carving and the most delicate sculpture are reproduced with the perfection of models, and with exquisite firmness of execution.—*Manchester Examiner.*

Professor J. Bete Jukes commenced on the 31st ult., at the Museum of Irish Industry, a systematic course of thirty lectures on "Geology and its application to the arts."

Mr. G. Davies, of Serle-street, Lincoln's Inn, Middlesex, C.E., has obtained a provisional protection for "improvements in the construction of iron or other metal beams, and in the machinery and apparatus employed for such purposes."

New Iron Plating for Ships.—Some private trials are now being made by Government with a new form of iron plating, and at the shortest distances every description of shot is shivered, and not the slightest impressions made.

COMPOSITE GRAVE MONUMENTS AND TABLETS.

A PATENT has recently been obtained by Messrs. George Smith and Co., Sun Foundry, Glasgow, for the construction of the above, and the following characteristics are claimed, viz., "that to remove the difficulties formerly presented as regarded the inscription on the panels, the framework *only* is constructed of cast iron, and is prepared to receive either marble, stone, or slate panels, which may be inserted independently." It is also alleged by the patentee that "the material is greatly susceptible of embodying designs—the most simple and massive as well as those of high artistic worth, combining delicacy and variety," and that "in these respects cast iron is infinitely beyond marble, stone, or slate." "A preservative coating to prevent rust," and by repetition causing "the retention of original sharpness and finish for ages" is also included. Their extreme *comparative cheapness* is emphatically put forward. We are at present unable to pronounce any opinion on its merits, but we may have occasion for further reference by-and-bye; meantime we must remark, that in *some* localities any innovation upon the monopoly that exists amongst manufacturers of memorials to the dead, and any improvement on the generality of the stereotyped, ill-fashioned, unartistic forms found in cemeteries and churchyards ought to be hailed as a desideratum.

Notes of New Works.

Mr. John Mullins, of Longford, builder, is the contractor for the erecting and finishing the tower of the cathedral in that town; expenditure, about £4,000. Also for erecting terrace walls to same; amount, about £500. Mr. John Bourke, architect.

Additions and alterations are being made to Lissbruck House for Mr. John Crawford, after plans by Mr. James Bell, jun., architect. Mr. John Mullins, builder; amount, £350.

A lodge is being erected in Trinity College, Dublin, facing College-street, intended as a residence for the Chief Steward of the University. The style is Italian: it is fronted with Ballyknockin granite, having bold cut stone lucarnes with segmental pediments; the cost will be about £900. Mr. M'Curdy, architect; Mr. Fetherstone, builder. [The unsightly old wall at present in front of this building is, we understand, to be removed. We would strongly urge on the Board of Trinity College and the city authorities the absolute necessity that exists in those days of improvement of sweeping away this disgraceful portion of the College boundary. The good offices of Mr. George Roe have, we believe, already been active in pursuit of this object]

Messrs. Vyse and Co., of Wood-street, London, are converting the premises at the corner of St. Andrew-street and Trinity-street into extensive warerooms. Cost, about £900. Mr. M'Curdy, architect; Mr. S. Bolton, builder.

An extension of the Passage railway to Monkstown is proposed, and the owners have been served with notice.

The new branch Bank of Ireland, at Tipperary, is nearly completed. It has a neat front composed of brick with Portland stone cornices, dressings, &c. An ornamental railing has also been erected, and the interior fittings are in a forward state.

Messrs. P. Lalor and Son, of Carlow, have been engaged for the last four months in the decoration of Ballinakill Catholic Church, and are said to have executed the work with much artistic skill.

The new Catholic church erecting at Raheny, and already described in this journal, is in a forward state, the slating of the chancel being finished, and the rest of the roof in progress.

The premises No. 62, Upper Sackville-street are being altered and remodelled, so as to be converted into extensive wine stores and vaults, for Mr. Lewis Heinekey, wine merchant. Mr. M'Curdy, architect; Mr. J. Nolan, builder. Cost, about £800.

Preliminaries for the construction of the Cork, Blarney, and Macroom Railway are said to be so far satisfactorily arranged.

A new minor model school is about to be erected at Lurgan on a site near the railway station. It will be of Italian design, with a roll and flat roof, campanile, &c. The cost may probably range from £5,000 to £6,000; and the building is being designed and will be erected under the superintendence of the architect to the Board of Public Works.

We learn that the Lords of the Admiralty have withdrawn from the Board of Public Works, the building arrangements connected with the coastguard stations in Ireland.

An important and handsome memorial structure, in the Gothic style, is about being erected at Prospect Cemetery, Glasnevin, after plans by Mr. John S. Butler, architect. It will present a quantity of elaborate carving and be terminated by a crocketed and finialed spirelet, attaining a height of 34 feet.

The side altars in the Metropolitan Church, Marlboro'-street, are being re-constructed in an improved manner, according to designs by Mr. J. J. Lyons, architect; Mr. Wm. Hughes, builder; Mr. Hibson supplying and fixing the marble work.

The building of the Ulster Hall in Bedford-street, Belfast, has been for some time in progress. The grand hall will be 138 ft. long by 63 ft. wide and high, and will afford sittings for about 3,000 persons, together with orchestral accommodation for 300 performers. A gallery 10 feet 6 inches in width will extend about three-fourths round the hall, and twelve distinct approaches affording easy access from spacious corridors be obtained. Over the vestibule there will be a minor hall, 63 feet by 32 feet, and intended for various purposes. In Bedford-street *three* entrances are provided, in Linen Hall-street *two*, and in Franklin-street *one*. Provision is made for a grand organ, and the acoustic properties of the hall are said to promise to be of the highest order. Mr. W. J. Barre is the architect; Messrs. Fulton the contractors.

Mr. James Connor, of Belfast, has been declared contractor for the erection of the new bridge over the Lagan at Ormeau.

Reviews.

The Royal Irish Academy Catalogue. By DR. WILDE.
Dublin: Hodges and Smith.

The second portion of this comprehensive work—evidencing a vast amount of zealous energy, research, and antiquarian lore, and destined to form unquestionably a glorious national muniment—is now published. The sub-classifications are multifarious; historical sketches and annotations are given in each department, and the illustrations are very exquisitely handled, both by draughtsmen and engravers;—the whole displaying such superlative mental and physical labour in compilation as only the giant mind and indomitable activity of Mr. Wilde would be competent to surmount. Even for one whose professional pursuits might bear to an extent upon the antiquarian, archæological, national historical, and various other subjects embraced in this work, its advent would be hailed with universal admiration; but how considerably are the merits of the author's Herculean undertaking enhanced when we are reminded of the circumstances under which it has been produced?—viz., *volunteered* and *gratuitous* labour to supply a *national want*—for so may be characterised the absence of a complete record of the contents of the Academy—and that too during leisure intervals snatched from arduous and important avocations of a totally foreign character. The third part is in progress, and on its appearance we shall have occasion to refer *in extenso* to the whole. Elsewhere may be found an interesting quotation from the subject of this notice.

Price on Gunpowder-proof Locks, Lock Chambers, and Drill-proof Safes. London: Spon, Bucklersbury; or the Author, at Wolverhampton.

Mr. George Price, of Wolverhampton, a well-known manufacturer of safes, locks, &c., on fire and drill-proof principles, has just published an elaborate treatise—the second by the same author—under the above title, in which he describes the various methods of different patentees, the means adopted by burglars to open locks and safes, the precautionary measures used to foil them, the contrast between one manufacturer's make and another, and concludes with a history of "the Bromley test," already noted in the columns of this journal, together with subsequent correspondence by Mr. Price relative thereto. Though certainly admitting the cleverness of the book, which is clearly written and copiously illustrated, a question would arise to our minds as to its prudential character for the community generally, inasmuch as that the exposition therein of experiments effected with great skill by notorious burglars, the means employed, the results in each case, the respective causes of *success* and *failure* might tend to add to the ranks of that fraternity, and induce some of the less experienced, but equally aspiring, members to try their hands likewise, especially when armed with so much information. However, we freely admit the author's capacity to deal both practically and theoretically with his subject, and moreover, doubt not that his inventions and improvements are highly appreciated; but these very considerations suggest a passing regret that he has not pursued a more independent tone, relying on *his own* merits, and without condescending to the disparagement of *others*.

The diocese of London contains a population of nearly two millions and a half, and is increasing yearly at the rate of 50,000 souls.

Miscellaneous.

Excavating Tunnels.—Mr. Gilbert, Coleorton, has invented an apparatus to excavate sewers, tunnels, &c., and at the same time to allow the building of the required number of rings of brickwork, without the aid of timber to prevent the slip from above, no more ground being displaced than is necessary, these being done as well in running sand or new ground as in solid firm ground, and effected in the following manner, as described by him:—I propose employing a cutting shield, of the form of the upper part of the tunnel or sewer, and supporting it by suitable framing, upon which are powerful screw-jacks, hydraulic presses, or other suitable power for the purpose of driving said shield forward. The shield travels over rollers on the top of the frame, and can be made to travel in a straight line, rise, fall, or turn a course by means of such rollers. The bearing prop or framing at the back of the brickwork may be formed in the shape of an X; the lower part thereof serving as an entrance passage to a waggon-road, where such is required for clearing away dirt, or other purposes.

The Great National Exhibition of 1861 in Belfast,—We perceive by the report of the meeting held recently, that the gentlemen who have kindly undertaken the laborious task of collecting subscriptions in Belfast have been requested to furnish their reports within a limited period. The subscription list at present amounts to about £850, but as at least £1,500 will be required to meet the expenses of the exhibition, we trust that such of the inhabitants of Belfast as have not yet subscribed will contribute liberally, and thus aid the committee in carrying out effectually an undertaking calculated to confer great advantages on the town. It would be a disgrace to Belfast if its contributions for this purpose should prove to be less than those of Cork and towns of minor importance. As the subscription list will shortly be published, we hope to see the gentry, merchants, and other respectable inhabitants of Belfast well represented upon it. —*Belfast News-Letter.*

The "Lamp."—This journal is regularly forwarded to us, and we recognise in its pages much that is pleasing and instructive. The contents are chiefly original, and where they are not so the selections are judicious, and evidence good taste. Moreover, the illustrations, though miscellaneous, are frequently of a pretentious architectural character, especially so, considering that the journal is not a professional organ, and that it takes its place amongst the cheap literature for the million. The editorial department is very ably presided over by an Irish barrister and eminent scholar, Mr. James Burke, A.B., who in addition to the successful accomplishment of his mission in conducting a journal devoted chiefly to those of a certain creed, produces a work to which none can take exception, and of which *all* must admit the merits.

Poisonous Paperhangings.—The Royal Engineers have received orders from the War Department no longer to permit green paper to adorn the walls of officers' quarters, and of other Government buildings. In some countries on the Continent, the police are stringent in refusing permission to decorators of the beautiful tints now brought out in this favourite colour; and the attention of our own authorities has been drawn to it, from the circumstance of medical men being called upon to treat officers for complaints, to account for the contraction of which they were completely at a loss. It is said that a gallant colonel, at Woolwich, who breeds and keeps a large stock of choice canaries, was greatly annoyed in finding the most valuable birds drooping and dying by threes and fours at a time. At length, his family being attacked repeatedly by throat and mouth complaints, apparently caused by arsenic, it was suspected that the deleterious substance was evaporated by the heat of the room from the green paper on the walls; and this suspicion proving, on examination, to be well founded, the order above alluded to was promulgated for future observance.—*Army and Navy Gazette.*

Architecture at the Catholic University.—Professor M'Carthy's class meets every Wednesday evening from 7½ to 9½ o'clock p.m. This is the *only* University in Ireland that has deigned to appoint a professor of architecture.

Gathering Mechanism for Sewing Machines.—One of the last and most striking improvements in the sewing machine is that made by G. B. Arnold, of New York, whereby plaits are made and secured in an accurate and beautiful series of gathers at one operation, and with the same rapidity as ordinary stitching. There are two ways of effecting this, both patented by the above-named gentleman. One invention (patented last spring) lies in the use of a double-feed, one part of which gathers the cloth while the other part feeds along under the needle. The other invention (patented last week) requires but one feed, with peculiar parts acting in combination with it. These improvements are making a considerable sensation throughout this country by adding very materially to the powers of this wonderful machine; and an agent is now abroad, instructing the artisans of Europe as to the nature of said inventions.

Multiplication of Photographs by Machinery.—A highly interesting paper was read not long ago before the American Photographic Society, and is reported in the *Architects' Journal*, of New York. By this paper it appears that 12,000 photographs or stereographs an hour can now be produced from a single negative by means of condensed or focalised light and simple machinery worked by a crank. A sheet of ordinary paper, sensitised, was exhibited, containing 800 of these photographs. Mr. Charles Fontayne, of Cincinnati, Ohio, is the inventor of the process. The prepared or sensitised paper is simply passed, in a continuous sheet, before the negative, in a box, where condensed light is made to penetrate through the negative and impress its image upon the paper, which it does in ·03 of a second for each impression. The condensing lens is seven inches in diameter. Thus, it is said, "the illustrations for a book, having all the requisite beauty and perfection of the photograph, may be turned out by the use of this machine with a rapidity wholly undreamed of either in plate-printing or lithography." The cost of engraving also will of course be dispensed with. All sorts of drawings, too, may be thus multiplied, as well as actual objects, photographed or stereographed, in cheap and endless profusion. The *Architects' Journal* publishes a print thus produced from a rough sketch by the ordinary ammonia-nitrate process, and of which we received a copy.

Physiological Considerations.—The injuriousness of imperfect drainage is said to arise from the noxious influence of all organic matters—animal and vegetable—when in a state of decomposition. That putrid flesh and vegetables are generally unpleasant, both to taste and smell, is a fact; but are they as injurious as they are unpleasant? Some putrescent matters are injurious when eaten, although many can be and are eaten with impunity; and all of them are injurious *if they enter the blood.* The surprising fact that the Indians kill their game with poisoned arrows, yet suffer no harm from eating the flesh thus poisoned, is intelligible to the physiologist, who sees that the poison of the arrow enters the blood of the animal; but the poison of the poisoned flesh, which is eaten, does not enter the blood. It is on the same principle that we can explain why an anatomist may spend day after day over putrid bodies (in an atmosphere the stench of which makes a stranger sick), yet suffer no harm beyond what would result from sedentary confinement in any other room; nevertheless, let this anatomist scratch himself with the scalpel which he has just used, and this little wound may be his death. He could breathe the air laden with the products of decomposition, and, if oxygen were sufficiently abundant for respiration, no harm would ensue; but he could not admit decomposing matter into his blood without serious injury. Putrid *substances* are poisonous only in the blood; but the gaseous *products* of putrescence are not poisonous. A stink is unpleasant, but it is not poisonous. We assume, of course, that the gaseous products are not too abundant to prevent respiration, otherwise the effects of imperfect respiration will ensue; but these are not cholera or fever.

THE PANTOMIME—THEATRE ROYAL.

Though apparently "the proverb should become somewhat stale" considering circumstances, nevertheless the annual festive celebration at the Royal as yet seems to lose none of its attractions. The Dublin public is termed fastidious and critical; yet we believe that there is none other more willing to lend an applauding hand where merit presents itself, in whatever branch of histrionic art it may be. Old and young look for the pantomime, each with a comparative anxiety—the former, perhaps, with the double intent of cool criticism and a desire to witness juvenile enjoyment, the latter with that truly beautiful innocence which alone characterizes tender age; but *one* and *all* must join in commendation of the present provision for their pleasure by the excellent caterer who guides the helm at our national theatre. Evidently talent has been brought to bear forcibly in each department, but especially in the scenic and musical. Mr. Glover has substantially realised his promises for future eminence, and Mr. Levey most excellently sustains that already acquired.

TENDERS

For erection of alterations and additions to Lessbrack House, for Mr. John Crawford. Mr. James Bell, Jun., architect.

J. Mullins (accepted)	£350
Hunt & Co.	300

To Correspondents.

J. M'G (Attended to); R. R. B. (Next number); T. F. (Quite at variance with previous expressions); J. M. (Have not seen drawings, and cannot say); W. P. (As you please); X. L. (We are not in a position to recommend definitely without *further* information). Received—J. F.; Clerk of Works; W. J. B.; F. L.; W. G.; W. W.; S. G; T. S.; Enquirer; T. M.

The Dublin Builder.

Vol. III.—No. 27.

LIVERPOOL TIMBER TRADE.

THERE is no article of commerce whose position in the market has more significantly important bearing on the state of affairs *generally* than that of timber. It is, of course, subject to fluctuations influenced by various causes, but an aggregate return of the *imports*, *exports*, and *consumption* for a year will incontestibly evidence either the temporary growth or decline in prosperity of a nation for that period. Judging, therefore, that the numerous readers of this journal, whose avocations more or less induce a special interest in this subject, might desire to accompany us in a statistical glance at the trade during 1860 at some of the chief ports in the kingdom, we commence with Liverpool, intending, however, in subsequent numbers to follow on with those of Dublin, Belfast, Cork, Limerick, &c. For the particulars hereunder we are indebted to the comprehensive annual circular published and forwarded to us by Mr. E. Challoner, an eminent timber broker and measurer in the town in question. The opening paragraph states that—

"The past year, but for the disturbance of the timber duties, would have been one of uninterrupted prosperity, owing to the animation existing in the manufacturing districts. But the shippers in British America of sawn wood (the form in which *their* staple is chiefly presented) being subject to much heavier cost of transit and labour, must henceforth be placed at a marked disadvantage in their competition with the European shippers, whose adventures become as it were assured to them in this country, by the comparatively small freight they have to pay.

"Until the past year, this difference of freight was always taken into account in fixing a scale of duty. Wood, being an import from our colonies, the freight of which, in many instances, amounts to more than even its cost at the port of shipment, this alteration of duty termed 'assimilation' must be always at the cost of the colonist, unless the *freights* could be also assimilated, which they never can.

"Neither has the reduction of duty on foreign timber this past year benefitted the consumer; the amount of duty forfeited by the customs having been divided by the foreigner as cutter and carrier, his competitor in the British colonies being his sure protection at market in this country.

"The existing rate of duty on colonial deals being equal to about 10 per cent. on the invoice, the amount of duty aggregated on the year's import into Liverpool is shown to be £20,513 against £205 received on foreign sawn fir; thus proving how little of European fir passes through this port. In London and other competing ports, foreign sawn fir much preponderates over colonial, and from these ports the interior is completely supplied.

"*Apart from political contingencies*, the present state and future prospects of the holders of wood at market here have seldom been brighter, on account of the advanced rates of freight likely to rule in the coming spring, the limited stock in this port, and the prospects of an active demand.

"Amalgamating, as usual, the import, consumption, and stock of colonial fir, both in logs and planks, and contrasting the same with the previous year, there appears to be as follows:—

Year ending January 23rd, 1861.

	Import.	Consumption.	Stock.
Logs,	5,610,104 cubic feet.	5,987,104 cubic feet.	2,253,000 cubic feet.
Planks,	10,256,895 „	9,951,645 „	3,576,870 „
Total,	15,866,999 „	15,938,749 „	5,829,870 „

Year ending January 25th, 1860.

	Import.	Consumption.	Stock.
Logs,	5,666,534 cubic feet.	5,974,234 cubic feet.	2,630,000 cubic feet.
Planks,	9,753,480 „	10,063,020 „	3,271,620 „
Total,	15,420,014 „	16,037,254 „	5,901,620 „

Showing an increase in the import of 446,985 feet, or nearly 3 per cent.; in the stock a decrease of 71,750 feet, or 1¼ per cent.; and in consumption a decrease of 98,505 feet, or ½ per cent.

"The following table contrasts the tonnage employed in the timber trade of this port last year with the previous one:—

From the 25th January, 1860, *to the 23rd January*, 1861.

	Vessels.	Tons.
Quebec ..	142	123,099
St. John, &c. ..	232	161,014
Baltic	51	14,385
Total ..	425	298,498

From the 27th January, 1859, *to the 24th January*, 1860.

	Vessels.	Tons.
Quebec ..	143	105,163
St. John, &c...	216	177,938
Baltic	70	26,006
Total ..	429	309,107

In the matter of American pine timber, the circular states that—

"During the past year the import from Quebec has been 4,744,109 feet against 4,143,789 feet in the previous year. The improved make and quality of this wood has largely increased its consumption, the stock of the port showing a decrease of 187,500 feet, when compared with that held at the close of 1859. Waney board pine has formed a large proportion of the past year's import, owing to the preference given to it by machine-makers, and the scarcity of late of the better class of St. John's pine; in some instances 2s. 4½d. per foot has been obtained at auction. The like improvement in size and quality has been extended to the square timber, on which account prices generally have been remunerative. St. John's pine, on the contrary, has fallen off in supply. The imports, beyond those from Quebec and St. John, have become unimportant. The last sale by auction of Quebec was at from 1s. 5½d. to 1s. 7½d., or 18⅛d. per foot average for middling quality of 61 feet average, and Waney board pine was offered by auction recently, but withdrawn for an advance on 2s. 4d. per foot."

The following are the returns of the mahogany imports—

"St. Domingo—	*Year ending Jan.* 23, 1861.		*Year ending Jan.* 25, 1860.	
The Import has been	1,083,801	feet, against	1,519,855	feet.
„ Consumption....	1,444,454	..	1,249,927	..
„ Stock is........	37,160	..	397,813	..
Cuba—				
The Import has been	87,953	feet, against	178,383	feet.
„ Consumption....	41,673	..	219,663	..
„ Stock is........	Nil	..	3,720	..
Honduras—				
The Import has been	2,246,584	feet, against	1,630,912	feet
„ Consumption....	2,196,454	..	1,618,762	..
„ Stock is........	216,280	..	166,150	..
Mexican—				
The Import has been	1,283,431	feet, against	1,066,710	..
„ Consumption....	1,421,331	..	845,510	..
„ Stock is........	177,100	..	315,000	..

"Of St. Domingo, the above shows a marked falling of in supply, while the consumption has exhausted the stock entirely of logs, and leaves but few curls. Cuba has fallen off in supply to one-fifth of the import in the year ending 1859. The deficient supplies of all Spanish mahogany have rendered the produce of the newer cutting districts of Laguna and Santana especially marketable, through the admirably made, large, and figured Wood lately brought to market from these ports. To-day the cargo ex Albina, from Laguna, brought from 6½d. to 9½d., or 7d. 5-16ths. per foot average. Honduras has largely increased in consumption, 2,250,000 feet being the import last year, against 1,630,000 feet in the previous year; the consumption in the past year 2,196,454 feet against 1,618,762 feet in the previous year, and the stock of 216,000 feet was this day reduced by the sale of 138,364 feet, ex Strang, at from 6½d. to 1s. 2d., or 8 1-32d. per foot overage. Mexican.—For the reasons assigned above, this description has become highly appreciated. In the year just ended, 1,288,431 feet received against 1,066,710 feet in the previous year, the consumption has been 1,421,331 feet against 845,510 feet in the previous year, leaving a stock to-day of 177,000 feet against 315,000 feet at the corresponding period of last year, the market being cleared of all wood actually unloaded. The above calculations are made in superficial feet of one inch, sale measure."

Of Baltic timbers it seems that:—

"During the past year 51 vessels laden with 14,385 tons fir, have arrived, against 70 vesels 26,006 tons during the previous year. The import has been 457,273 feet of Danzig, 10,000 feet memel, 6,000 feet of Riga, and 64,596 feet Norway; aggregating 537,959 feet against 956,468 feet in the previous year. The consumption has been 668,959 feet against 774,068 feet; and the present stock is 200,500 feet against 331,500 feet held at the close of 1859. This decrease in the imports into Liverpool from the Baltic is principally accounted for by the great difference in freights to the East as compared with those to the West Coast, and the cost and difficulty of transit to the interior from this port."

Of Deals.—"The import has been 562 standard against 2,189 standard; the consumption 2,091 standard against 1,108 standard; and the stock now is only 483 against 2,012 standard held at the close of 1859."

And of Battens.—"The Import has only been 60 standard, and the stock is nearly exhausted."

Talbot-street.—A correspondent of the *Freeman's Journal* in urging attention to the considerable obstruction to the traffic of this leading and populous thoroughfare, offered by the unsightly old building at the corner of Talbot-street, where Marlboro'-street intersects, says, "I see a notice in your journal from the *Dublin Builder*, concerning a new flagway in same street, at an expense of some four or five hundred pounds, but ventures to add that the removal of the concerns in question would be of much more importance." [It seems to have escaped the notice of the writer that we had already drawn special attention to the desirability of the suggested removal, as may be seen by reference to page 176, vol. ii.—Ed.]

HOLYCROSS.

Holycross, with its beautiful and picturesque Abbey, the ruins of which are more imperishable than many modern buildings, is situated on the western bank of the River Suir, about two miles from Thurles, and nineteen from Clonmel, in the County of Tipperary. This Abbey was formerly a Cistercian Monastery, founded in the year 1182 by Donald More O'Brien, King of Limerick, surnamed Donald the Great, who died in the year 1194. Although many celebrated writers, as Archdall, Ledwich, &c., have ascribed the foundation to his son, Donald Carbragh O'Brien, yet the existence of the foundation charter leaves no doubt on the subject. The monastery was originally built in honour of a supposed piece of the true cross (hence its name), presented by Pope Pascal II. to Murtogh, monarch of Ireland. This relic, set with gold and gems, was preserved by the Ormond family, and transmitted by them through the family of Kavenagh to the present time.

The Abbey, as it at present exists, consists of a nave and lateral aisles, choir and transepts, and four small chapels, two at either side of the chancel, with the remains of the cloisters, chapter-house, &c. The nave and lateral aisles communicate by arches, are entirely unroofed, and are much less ornamented than the other portions of the building; but the beautiful western window is still in perfect preservation; the mullions and tracery, chiselled and hand polished with the highest finish, preserve their sharpness uninjured, although exposed at both sides to the weather for centuries. Four well-proportioned and lofty arches, leading into the choir and transepts, with delicately groined roof, support a square tower of high finish and in excellent preservation. The transepts present nothing worthy of particular notice; the southern one leads by a flight of stone steps through a small doorway to the top of the cloisters; this doorway and connecting balustrade are of recent construction. Two of the small chapels open into the south transept from the east. Each of these chapels has a window of singular beauty and perfect proportion; indeed the several windows of Holycross, each different in tracery, cannot be equalled in this country both for exquisite finish and beauty of design. Separating those two chapels, and supported on either side with small twisted columns, is an arched space, than which nothing, perhaps, more remarkable exists in any of the old ecclesiastical buildings in this neighbourhood.

We now come to the chancel, which contains a fine east window, the tracery of which, with many of the bosses and delicate ornaments of the groined roof within, have suffered considerable injury—more from the hands of barbarian man, than from the wear and tear of the elements. This has been, as far as possible, repaired by the Rev. Dr. Wall, into whose possession the property of Holycross came, by purchase, some twenty years ago. The southern wall of the chancel contains a supposed monument, celebrated for its great beauty and for the almost interminable discussions it has given rise to amongst antiquarians. This, the finest specimen of its kind at present existing in Ireland, consists of three arched compartments, surmounted by a canopy and frieze of the most florid pointed style, and much more richly sculptured than the building in which it is placed. About one third way up one of the shafts, the remains of a little cherub or angel appears, evidently sculptured from the solid stone, but now much defaced; the intention of this strange protuberance, which is attached to one pillar only, affords but little prospect of a satisfactory solution. The armorial bearings on this structure are described by Dr. Petrie, one of our most learned antiquarians.

The table of the monument is a stone slab, with foliated cross, acknowledged from its design to be considerably older than the rest of the structure, probably coeval with the original abbey itself. O'Halloran and many others, until recent times, have taken for granted that this was a tomb erected in honour of the founder, Donald More O'Brien, whose death took place, as we have before stated, in 1194. The architecture of the structure itself, however, bears internal evidence that it could not have had such an early existence; but the slab might have been a portion of his monument, although it could not have formed part of the original altar-piece of the building, as stated by some authorities.

But many ecclesiologists, accustomed to note the fittings of ancient edifices built for the celebration of Roman Catholic rites, take a totally different view of this structure; amongst them, Mr. Prim,* and his learned fellow-secretary of the Kilkenny Archæological Society, the Rev. James Graves. They argue that this is a set of sedilia or "sedes majestatis," being intended as seats for the priest and his assistants during the celebration of High Mass. These recessed seats are common enough in the southern walls of the chancels in Roman Catholic abbeys, and drawings and descriptions of some of them are given by Mr. Prim; one in particular, that of Callan Abbey, bearing a very strong resemblance to the structure at Holycross. Notwithstanding all that has been urged to the contrary, frequent personal inspections of this highly-ornamented triple-arched recess, lead me to believe that it was erected as the sedilia of the abbey church, its accompanying piscina or recessed basin for washing the chalice which had contained the wine being strongly corroborative of this supposition. The true measurement of the seats between the pillars is not 18 inches, as mentioned in the paper before referred to, but 24 inches for the centre seat, and 22½ for the side arches, the height from the original floor of the chancel being 23 inches, as far as can now be computed. These measurements, lately made with the greatest accuracy, present no difficulty for even a full-robed abbot finding ample room for his accommodation. It is true that the Abbey was founded as early as 1182, and that the architecture of the structure in dispute (the perpendicular or third pointed) proves *it* not to have been erected until about 1400; but the flamboyant windows of the chapels, and the mouldings, capitals, and other ornaments of the Abbey itself, clearly show that almost all the entire ruin—if not all—belongs to the same period, and that it must have been rebuilt about the beginning of the 15th century.

It has been stated that the fact of human bones being found in a grave under the slab-stone of this structure, on its being examined during the repairs of the Abbey a few years ago, "subverts all speculation, and sets the sepulchral character of the monument at rest for ever." Now, it seems to me highly improbable that the original architect of this beautiful ornament to the chancel, would have used an ill-fitting cross stone, even though it was a century or two old, which would necessarily disfigure the most elaborate specimen of his work in the Abbey. Is it not much more likely that when the sedilia came to be disused, that some one connected with the place removed the original seat and made use of the recess as a burying-place? And what would be more probable than substituting this old cross stone as a monumental slab, instead of the original seat of the structure itself, which may have been broken during its removal? It has been stated as unlikely that the monks would commit such a sacrilegious desecration; but anyone who has examined the numerous monastic buildings in this country, will find abundant instances of such stones having been used up for different purposes in all ages. Several instances of the kind were discovered during the recent alterations, in the year 1857, in St. Mary's Church, Clonmel. To prove that such desecrations were not confined to the middle ages, we have only to state the fact, that even in the 19th century, during those alterations, a large cross stone, that originally formed part of the altar of White's Mortuary Chapel, and had lain in the churchyard for centuries, an object of curiosity, if not of veneration, was cut through the centre of the cross to form a threshold stone for a doorway, although a special request from the Archæological Society was made to those in authority to preserve, if possible, all such relics.—*Hemphill's Abbeys, Castles, and Scenery.*

New Monster Hotel at Bray.—The architect, Mr. E. O'Kelly, and the projector, Mr. John Brennan, have been recently busily engaged in marking out the foundations of a hotel on a very extensive scale, in this rapidly-increasing locality. The site may be looked on as one of the finest in the kingdom, views of great beauty and extent spreading in panoramic form on every side—the north-east angle of Mr. Quinn's field, opposite the railway station, being the spot marked out. From the plans and elevations exhibited on the ground, the establishment will be on the most extensive plan of American hotel accommodation. Its front elevation will, for 120 feet, face the Quinsborough-road; its east front the railway station. It is to contain large assembly, coffee, sitting, and smoking rooms, and some 180 bedrooms, and the most valuable feature of all for Bray visitors, an extensive restaurant. That such an establishment is much wanted here is well known, and it need not at all interfere with the first-class establishment already existing. It will, without doubt, increase the tide of summer visitors to Bray and Wicklow, and by so doing will benefit the railway, the locality, and the county.—Correspondent of *Freeman.*

New Water Elevator.—Mr. Robert Nelson, an American, has invented a new water elevator, in which the vacuum is produced by the combustion of volatile matters, among others, naphtha. The elevator consists of a large cylindrical reservoir, at the base of which the suction-pipe is placed. In the upper portion are several valves, communicating with a reservoir of naphtha and a little furnace placed between this latter and the cylinder. Upon closing this latter it is sufficient to light the little fire, and allow the naphtha to fall upon it drop by drop; the vivid combustion that ensues, creating a vacuum, causes the water to rise rapidly in the cylinder, as much as 100 gallons at a time.

Rendering Textile Fabrics Uninflammable.—A patent has recently been obtained for the above purpose, by a Mr. Able. His method consists in precipitating a basic silicate of lead within the textures, by first saturating them with a solution of basic acetate of lead, then drying, and afterward treating them with a solution of silicate of soda.

Railway accidents, attended with serious, and in some instances fatal consequences, have prevailed lately very much in England.

THE DIPLOMA—"TO BE OR NOT TO BE."

WHAT'S the question! which for a lengthened period has been engrossing the chief consideration of the architectural fraternity, and which recently—as may be seen in another portion of this journal—has received, to a certain extent, an apparent solution. Without entering into it fully at present, various considerations would seem to suggest themselves with reference thereto, and which may be enumerated as follows:—Will the diploma be productive of any *practical* benefit to the profession and the public, by limiting architectural practice to such only as shall be in all respects competent? secondly, will it effectually exclude all intruders? and thirdly, assuming that it will do so, will such effect be *general* throughout the kingdom, or merely *local*, or for such districts as have subscribed to the voluntary examination? Regarding the probability of its *practical* results, we may ask, is that section of the public engaged in building speculations to understand that an additional guarantee will be afforded, both in artistic and constructive departments of their works, if confided to a diploma'd architect? and another, will the chances of casualties and litigation be lessened by virtue of that magically inflential document presented to the professor by the Inst. B. A.? Moreover, must all the present practitioners, be their professional position what it may—unless by grace especial from this worthy body—withdraw from outside the pale and hide their diminished heads, or submit to the humiliating alternative of—like schoolboys—being paraded before their masters, and subjected to an examination test? The Institute dignifies the movement with the title of "voluntary," but this seems to us very shallow indeed, as its initiatory step is to constitute itself into a dictatorial tribunal, exempted from the voluntary test, considerately consenting "to take upon itself the labour of instituting an examination tending to promote a systematic professional education." The diploma should be either, to all intents and purposes, *voluntary* or *compulsory*. As at present constituted—or proposed to be—it partakes equally of both elements, and those who have neither time nor necessity to go in for a diploma voluntarily, may be compelled to do so by the pooh-poohs and snubs of juniors—ree-raws—having nothing else to do but brush up for a display. The tone of the provincial societies is mostly favourable to the movement, though at the Liverpool Architectural Society some strong difference of opinion prevailed; of course, that of the profession in Ireland was not obtainable, there being no association or institute to pronounce it—hence the questions are suggested, shall the movement extend *here?* and, if so, who are to be the judges? We confess to little faith in its well working *here;* but as it is hardly fair to pronounce a definite opinion in the present stage of proceedings, we postpone further consideration until the curriculum and bye-laws, at present in course of preparation by the Institute of British Architects, be published.

THE ROUND TOWER CONTROVERSY.—THE BELFRY THEORY EXAMINED.

BY RICHARD BOLT BRASH, ARCHITECT.

HAVING in a former paper* endeavoured to show that we have no historical evidence as to the original uses and era of the round towers of Ireland, and that the word *Cloch-teach*, used in various passages of the native annals, cannot refer to them, I will now proceed to consider the question of their date and use, as discussed by Dr. Petrie †

That zealous and learned antiquary ascribes these structures to a period ranging from the fifth to the thirteenth century, and their erection to the Irish Christian converts; firstly, for belfries; secondly, as monastic keeps, or places of refuge in troublous times, and for preserving the Church plate, relics, and other valuables possessed by their infant and struggling Church; and, thirdly, as watch-towers. Upon the latter use, however, he does not much insist for want of sufficient evidence.

On the belfry question, however, he takes a positive position, and brings to bear upon it a vast amount of learned research, and patient ingenuity. I would remark, in the first place, that the very early period admitted for the existence of these towers is forced upon the Christian theorist by the remarkably ancient character of those hoary structures, particularly one class of them, which amidst all the reparations and mutilations they have undergone, still present to the archæological critic the type of an architecture which has no parallel in that of any known Christian people, but has a perfect and startling accordance with the Pagan arts of design and construction, as still exemplified in monuments of ascertained antiquity all over the world. This branch of the subject is most interesting, but of so extensive a nature that the scope of my present paper will not allow me to enter on it. It is, however, my intention to devote a special article to the consideration of this important phase of the question.

That the Irish converts erected belfries, in the fifth and succeeding centuries, is improbable, and is likewise opposed to the testimony of architectural history, and to the negative evidence of our native annals. *Belfries* must, evidently, have followed the introduction of *bells* into Christian worship and uses: I say belfries, meaning high structures specially raised to hang large bells in; for it is an admitted fact, that the custom of erecting lofty symmetrical buildings, ornamental, monumental, or commemorative, whether in the shape of obelisks, solid columns, or hollow pillars roofed in, is of unknown antiquity. Our present business, however, is with ecclesiastical towers, erected specially for the purpose of suspending large sonorous bells in, to call the neighbouring community to the public worship of the sanctuary. The date of the introduction of bells into Christian solemnities is involved in much obscurity. Bells were used by the Etrurians, Egyptians, and Romans. The bells upon the bridles of horses, also upon the garments of the high priest, are mentioned in Scripture, and various substitutes for them are alluded to by ancient writers. Pliny states that bells attached to chains were suspended from point to point of the pyramids that composed the mausoleum of Porsenna, King of Etruria. Fosbroke (vol. i., p. 229) mentions that they were used in the mysteries of the Cabiri, the Corybantes, and Bacchus, and that they were worn on the tunics of the Bacchantes, as a melodious accompaniment in dancing. They were carried in funeral processions to warn the Flamen of Jupiter least he should contract any impurity by hearing the funeral flutes. The bells of a Priapus, at Portici, were of bronze, wrought over with silver. Suetonius states that Augustus Cæsar suspended a fringe of bells round the eaves of the Temple of Jupiter Tonans. Hart, in his *Ecclesiastical Records* (p. 245), mentions that, before the introduction of bells, the faithful were summoned to public worship by the sound of a table of wood, brass, or iron, struck like a gong: nor was the use of this totally discontinued for some centuries after, as such instruments are mentioned in Lanfrane's *Monastic Institutes*, written after the Norman Conquest. In the Greek Church a hollow table of sonorous wood was used for the same purpose: when smartly struck with a hammer, it emitted a sharp ringing sound. Such an instrument is employed in the Armenian churches to this day.

The first mention of ecclesiastical bells is about the year 400. We are informed that Paulinus, a bishop of Nola, in Campania, introduced them into Christian worship; this introduction must exclusively refer to the altar services, as previous to this, we have no mention of bells used in the solemnities of the Christian church; the simplicity of the apostolical doctrine and worship having probably yielded by degrees to the influence of the more pompous ceremonial of the pagan ritual. The *tintinnabula*, subsequently introduced by Pope Leo I., about 458, were so small that six or eight of them were hung to one wheel. Early in the seventh century we have an ordinance of Pope Sabinian, enacting that the canonical hours should be marked by the ringing of bells. The custom and use of hanging a number of small bells to a wheel, as above mentioned, is illustrated by a quotation from Du Cange, *v. Rota*, in Fosbroke, vol. i., p. 98, mentioning that a wheel was fixed to the wall near the altar, on which were hung a number of bells, and which was whirled around at the elevation of the Host. There is no doubt that bells were used in the liturgical services of the Roman Church long before they were exalted in towers to summon hearers to public worship. It is more than probable that the first employed for this purpose were large-sized hand-bells, rung at the church-door, or from the external galleries that were common in the *façades* of Lombardic churches in Italy for several centuries. It is also extremely probable that the earliest belfries were of wood, framed and fixed in proximity to the churches. Thus, Gregory of Tours affirms that Leo, his predecessor, was an artist of great skill, particularly in works of carpentry; and that he erected towers, which he covered with gilt bronze, and some of which lasted until his time. Whittington, in his *Historical Essay on Gothic Architecture* (p. 22), states, on the authority of Felibien, (*Arch.* iii. 159, iv. 232.) that Dagobert completed the tower of Strasburg Cathedral A.D. 643, which was principally composed of wood. So late as 1145 a wooden bell-tower, covered with lead, was erected at the Cathedral of Chartres, which was in existence in 1506, when it was burned by lightning. [Note to Whittington's *Essay*, p. 182.]

As from Rome emanated all ecclesiastical forms and ceremonies, and as the introduction of bells into Christian worship is undeniably due to her, so we must naturally look to Italy for the first examples of belfries or bell-towers. The first bell-tower recorded to have been erected in Italy was that added to old St. Peter's at Rome, by Pope

† Petrie's *Origin and Uses of the Round Towers of Ireland.*

Stephen III., between A.D. 752 and 757. See Hope's *Architecture of Italy*, (vol. i., p. 276,) who quotes, as his authority, Anastatius Bibliothecarius. Knight, in his *Architecture of Italy*, (p. 28,) says, "that bells were not used in connexion with churches until after the time of Paul I. Adrian I., who was elected in 772, erected the first belfry; it was of a character very similar to that represented in the engraving annexed, *and became the model after which most of the ancient belfries of Rome were designed*."* The characteristics of these ancient Roman belfries,—many of which remain to this day,—are thus given by Hope (vol. i. p. 277): "At Rome also the towers are all square, but with the stories marked by different cornices or string courses, the divisions between offering a certain number of small arches, with or without columns clustered together, with perhaps a canopy or tribune for a Madonna near the top; and medallions of porphyry, serpentine, or other marbles, inserted in the brick surface." See also the Architectural Publication Society's volume for 1818-9, article "Campanile," (p. 3). The dates of some of these square Roman brick towers are well ascertained. S. Giorgio, in Velabro, was erected by Pope Zacharias, A.D. 745 to 752; Sta Maria, in Cosmedin, 760 to 780; S. Giovanni Laterano, 750. The oldest of the square towers of San Ambrogio, Milan, was erected in 850; the second in 1143; the tower of San Zeno, Verona, in 1145; the leaning tower of Bologna, in 1116; that of Pisa, in 1174. The foundation of the square tower in the Piazza, at Venice, was laid in 889.

Speaking of the Venetian towers, Hope says (vol. i., p. 277):—"At Venice, again, all the steeples are square, and without distinct external string-courses, but divided on each side into two or three panels, running uninterruptedly from their base to their top, crowned by a small square or octagon belfry." Again:—"The towers of the north of Italy are also square, more marked by vertical panelling; the string-courses, usually flat, are very secondary features; the arcades are not perforated to the same depth; and the cushion capital is not found." [Architectural Publication Society's vol. for 1848-9, article "Campanile," page 3.]

There is another class of church towers in Italy to which the advocates of the Christian origin of the Irish Round Towers have turned for help to sustain their cause. I allude to the circular towers of Ravenna: these structures are of undoubted antiquity, but not more so than the brick towers at Rome, which they exactly resemble in every thing except their circular form. Hope (vol. i., p. 277) thus describes the Ravennese towers:—"Cylindrical, *and like a tube of equal diameter from top to bottom*, and all articulated, or showing external string-courses, marking every higher internal floor, some of these stories offering single round-arched windows, others clusters of two or three; low roofs cover the tops." The clustered windows are divided by small slender columns, having the cushion capital, which feature is general in all Roman brick towers. It is not to be supposed, however, that all the church towers of Ravenna are circular; there are several square towers, exactly similar to the Roman ones, and having details identical with the circular ones. A list of these towers is given in the *Builder* (London, 1849, pp. 243-4), where the writer, treating on the strong resemblance and identity of construction and detail between the Ravennese and Roman towers, remarks, that the windows in the towers, square and round, are almost all similar, in the peculiar deeply recessed columns and small arches above, to the Roman brick ones. There are very few strings, and these few are formed merely of brick laid angle-wise between two rows of bricks, almost flush with the face; they have no details. The crowning cornices are in a similar style, but larger and bolder. The columns have sometimes slightly carved capitals, in the Norman style.

Stairs were carried up in these towers; in the square ones they ran from angle to angle, between two thicknesses of walling; in the circular ones the steps wound round a newel, like the turret-stairs of castles and ordinary church-towers. The author of the article "Campanile," in the publication before alluded to, thus, in general terms, describes the early structures of this class:—"We find that the early 'Campanili' were simple towers, perforated by semi-circular arched openings, carried on columns or piers, not very artistically arranged, arising abruptly from the ground, without base or plinth mouldings, undiminished to the summit, and divided by numerous string-courses into stories of nearly equal height."

I have been thus minute in describing these ancient towers from reliable and trustworthy sources, in order to show that there is no resemblance whatsoever between the circular towers of Ravenna and the Hiberno-Celtic, except their circular form. What other points are there in common between those stair-cased, many-floored, and many-windowed structures, with their columned dressings, their brick ornamental string-courses and cornices, and the tall, slender, tapering, exquisitely proportioned, yet massive, masonried tower of Ireland, with its stone-lintelled Cyclopean doorway, its few and diminutive window opes, usually square or angular headed, its 4 attic windows facing accurately the cardinal points, and its overlaid stone roof?

The date of the erection of the Ravennese towers has not been fixed. Their architectural details would take them as far back as the eighth, or as late as the tenth, century; but it is not by any means probable that they are earlier than the eighth, from the fact that church-bells had not come into general use at an earlier period, and that at Rome, where we should naturally look for the earliest introduction of all ecclesiastical adjuncts, bell-towers were not erected before the middle of the eighth century. I would once for all quote the opinion of one who had carefully and laboriously investigated the subject of Italian ecclesiastical architecture:* speaking of the Roman basilicas erected at the first great development of Christianity he says:—"The only universal addition in Rome to the former sacred structures was after steeples had begun to spring up in the seventh and eighth centuries, that of one of these appendages to each of the old churches." Yet with all these facts and weight of testimony staring us in the face, we are called upon to believe that the Irish erected ecclesiastical bell towers in the fifth, sixth, and succeeding centuries.

That bell-towers originated in Italy, is beyond all manner of doubt; we can trace their progress into Northern Italy, into Southern France, and Germany, where the Italian type of tower is plentiful to this day: nay, the influence of that original form was felt through Christian Europe; and, even in Britain, the so called Saxon towers, such as Earl's Barton, Sompting, Brixworth, &c., in their square form, vertical panelling, coupled windows, with columns or baluster shafts, and the cushion capital, point unmistakeably to the original Italian type of bell-tower. I shall not here pursue this branch of the subject any further. It is quite sufficient for me to establish, as I hope I have done, that we have no authentic record of the erection anywhere of lofty stone or brick towers, specially for the reception of ecclesiastical bells, before the eighth century; nor have we any reasonable grounds for supposing that such were in use previous to that date.

The ages generally assigned to the oldest remaining towers in France and Germany, and to those in England usually called Saxon, is consistent with the date given for the introduction of bells and bell-towers in Italy, allowing a reasonable period to elapse for the gradual introduction of this new feature in ecclesiastical architecture, and taking into account the difficulties of communication then existing, the dislike of innovation, and the troubled state of Christendom in those remote and semi-barbarous ages.

I shall here leave my readers to conjecture, if they can, how the Christian Irish came to have bell-towers in the fifth, sixth, and seventh centuries.

In order to give some colour to this early erection of towers in Ireland, Dr. Petrie has attempted to establish the use of bells in this country at a very early period: his authorities are monkish legends, and Lives of Saints of the most apocryphal character, whose statements, as the truthful and erudite Lanigan has shown, if not entirely unworthy of credit, must, at least, be very unsafe upon matter of fact. Various passages from these legends are quoted by that learned gentleman, such as, that St. Patrick, who came to Ireland A.D. 452, abundantly distributed bells; that he had a bell-ringer, one Sinell, who rung the bell in the Cloigteach; that he had three artificers, named Asicus, Biteus, and Tassach, who fabricated such utensils with admirable art; that one Dageus was a famous bell-founder in the sixth century, and that he not only fabricated "bells, croziers, crosses, &c., but also shrines; and that though some of these implements were without ornament, others were covered with gold, silver and precious stones, in an ingenious and admirable manner." How unlikely all this is to be true must be apparent from the following considerations:—The early Irish missionaries were poor, zealous, fervent, simple in manners, plain in attire, rigid in morals; they brought with them neither silver, gold, nor precious stones; their language was that of the apostles of old to the blind man at the beautiful gate of the temple, "Silver and gold we have none, but such as we have give we unto you." They came to preach the Gospel of peace to a nation of idolaters, and the weapons of their warfare were not carnal but spiritual.

I have already stated that the introduction of bell-towers into Ireland, at the period or periods mentioned by Dr. Petrie, is contrary to the negative evidence of our native Annals, to which source he entirely appeals. Now, admitting for argument's sake, that the word *clochteach* signifies a bell-house, how comes it that a belfry is not mentioned under this appellation before A.D. 950, the earliest notice or mention of the term that Dr. Petrie has been able to produce? We have various terms for churches, and various parts and classes of ecclesiastical structures, specially and repeatedly mentioned, centuries previous to that date, but not one word about a *clochteach*. The natural inference is, that no belfries existed; that such appendages to churches were not in use, for if they were, surely such lofty imposing and important structures would not have been passed over in silence, when *Duirthechs* (oak churches or oratories), *Erdams* (porches), and *Cucines* (kitchens) are specially referred to.

(To be continued.)

* The Italics are mine.

* Hope's *Historical Essay*.

ST. PATRICK'S BRIDGE, CORK.

IN a former No. we noted the progress and characteristics of this important structure, and were pleased to find during a very recent personal visit that all the constructional difficulties as regarded the foundations for piers and abutments had been most ably surmounted, under the eminent practical direction of Sir John Benson, by Mr. Joshua Hargreave, the contractor, with whose names that of the clerk of works, Mr. Barnard, deserves to be most honourably associated. The local *Constitution* gives an admirable description of additional particulars to those already recorded, and from it we quote the following:—

"Upwards of 100 stone cutters, masons, and labourers are constantly employed in forming, dressing, and completing the stones and masonwork, and the formation of the arches has now reached a point which, while evidencing the conscientious care and surveillance exercised in every department, justifies the anticipation that when finished it will constitute one of the principal ornaments of a city which has hitherto been rather poorly furnished either in the number or the quality of its architectural embellishments. One of the most important and striking advantages which the new bridge will afford over that which met its destruction in consequence of the remarkable Flood of November, 1853, will be the almost perfectly level and spacious roadway it will offer for carriage traffic, a matter of the utmost consequence with a bridge which will form the principal thoroughfare of the city, and over which so many heavily laden vehicles must daily pass. The elevation, reckoning from the approaches at either end to the middle of the roadway over the centre arch, will not exceed 18 inches, which along a length of 245 feet is at the rate of only 1 in 164—an incline almost imperceptible, and being in fact purposely formed with the object of carrying off the surface water, and preserving the roadway dry and fit for traffic during the winter rains. In the width, as well as in the incline of roadway, the bridge will be a manifest improvement upon that which it is destined to supersede, being in fact the widest in the United Kingdom, with the exception of the new Westminster-bridge, one of the handsomest of the numerous modern structures which span the Thames. The entire width of the new bridge, from parapet to parapet, will be 60 feet; this will afford a roadway of 40 feet, and two footpaths of 10 feet wide each. This width is exclusive of the sweep at approaches, which will form four quadrants of about 10 feet radius, and adding about 20 feet to the width at either end.

"The material employed is almost entirely Cork limestone, with the exception of some few of the more massive portions of the foundations, procured from Foynes. Some small amount of the material was had from quarries at Midleton. The stone for the arches has been furnished almost entirely from Beaumont quarries.

"Little now remains to be effected but the completion of the arches and the formation of the roadway and approaches. The foundations of the piers and abutments were laid in massive iron 'casemates' or chambers lowered into excavations extending several feet below the bed of the river. Four of these were employed, one for each of the two piers, and one for each of the two abutments. They consisted of massive iron chambers strengthened in the interior by strong bars of cast iron. The excavations having been first made to the requisite depth, and the beds brought to a level with concrete, each casemate was lowered into its position by a moveable crane working on a timber bridge and tramway temporarily erected for the purpose. The spaces inside and outside the casemates were then packed tightly with concrete. The magnitude and importance of this portion of the work, on which the safety and durability of the superstructure entirely depend, may be estimated from the fact that the casemates for the piers were each 90 feet in length, 10 feet 6 inches wide, and 7 feet 6 inches deep—the metal being proportionally thick. The foundation stones of piers and abutments were lowered into their beds with the moveable crane, and firmly set with hydraulic cement.

"The centerings of the arches are formed of a series of massive ribs of Memel timber, strengthened by a series of thick framework of the same material. Along the circumferences of the ribs or timber arches a series of transverse planks are ranged close together, on which the masonwork of the arches is laid. At the points where the arched ribs rest on the upright supports a number of large wedges or bolts are inserted, which when the masonwork is completed will be driven out, the centerings will slip down some three or four inches, leaving the masonwork partially unsupported and free to settle down into its permanent position. The form of each of the three arches constitutes a segment of an ellipse, affording a greater width of waterway and also a flatter crown than the circular arch. The versed sine of the centre arch is 19 ft. 6 in., and that of each of the others 18 ft. 6 in., there being but one foot difference in height between the middle arch and the other two.

Nearly the entire of the stones for the arches have been dressed to the required dimensions. For this latter purpose timber models were furnished to the stone cutters, giving the section of each stone, of which about 60 will go to make the circumference of each arch. The width of each section is uniformly about 14 or 15 inches, and the height three feet at the springing of the arches, diminishing to about 2 feet 6 inches at the crown. The weight of each stone varies from 15 cwt. to one ton. They are set in position with the moveable crane, and cemented with hydraulic mortar.

"The balustrades will consist of a series of neat pilasters of cut stone, capped with the same material, the height from the footpath to the parapet being 3 ft. 6 in. The total length of the bridge from abutment to abutment will be 183 feet, and from quay to quay 215 feet.

"About one-third of the masonwork of the northern arch has been now completed, and one fourth of the two others. For the arch sheeting alone nearly 1,000 cube yards of stone will be employed. The total number of stones required for the formation of each arch will be about 1,200.

"After the completion of the arches, the most important portion of the remaining work is the formation of the roadway. To effect this and secure a level and firm surface for traffic it is intended to build a series of broad and parallel walls at nearly equal distances from each other along the entire length of the bridge—the heights of the walls at the various points of the arches will be increased or decreased, so that the summits may present a nearly exact level. A row of stout planks corresponding to the width of the bridge will then be laid across the summits of the wall to form a basis for the material of the roadway. This portion of the work is not expected to require much time, and we may now look forward before many months shall have elapsed to the completion of a structure which will reflect credit alike on the talent of the architect, the energy and skill of the builders, and the public spirit of the citizens by whom it was projected and carried out."

INCRUSTATION OF STEAM BOILERS.

MR. HENRY RANSFORD has addressed a letter to the "Society of Arts Journal" on this subject, from which we quote the following:—

"I tried the experiment on a 30-horse tubular boiler. In addition to the blow-off cock at the bottom, another was fitted over the fire pan, at the usual level of the water, and to the end of it, inside the boiler, was screwed on a funnel of sheet-iron, partly flattened, so that, on the cock being opened, anything floating within eight or ten inches on each side was drawn through. The engine-driver had directions to open the lower cock once a day, and the upper one when he saw the water in the glass gauge was thick, and keep them open until the water ran clear, but never to blow out the boiler as formerly. Three or four gallons from the lower, and half that quantity from the upper cock was sufficient to carry off all thick and dirty water. At the end of *three months*, first allowing the water to get nearly cold, the boiler was emptied; a stream of water was then introduced by the man-hole, and the tubes thoroughly washed. On examination the under half of the tubes was as clean as the day they were made, the upper half discolored, but no scale, and the sides of the boiler in a similar state; on the bottom was about half a bushel of thin scale, broken up into small pieces, that apparently had fallen or been washed from the tubes; thus, after three months' work, there was nothing to do but to get up steam again. The secret consists in never blowing out the boiler when hot, the usual custom, as the result is—the heat of the tubes and sides instantaneously convert the soft deposit into a hard calcareous substance, and every time the boiler is blown out, an additional stratum is added. If the man-hole is taken off on the Saturday afternoon, and the flues opened, the water is cold enough to run off by Monday morning, so that no time is lost, and I have no doubt the hot water might be allowed to run off on the Saturday, provided an equally large stream of cold water was allowed to run in at the same time, until the boiler and tubes were cold. I will merely add, the water was pumped from the Thames, and allowed to settle before being used for the boiler. There is no reason why the plan should not answer equally well for locomotives."

An ancient statue of calcareous stone, four and a half feet high, recently dug up from the excavations of Nineveh, and representing the King of Sidon, has just been placed in the Assyrian Museum of the Louvre. The archæologists are visiting this statue with great curiosity and interest.

The provisional committee of the Tralee and Tarbert Railway have decided on abandoning the bill for the present.

THE ARCHITECTURAL ELECTION AT THE ROYAL HIBERNIAN ACADEMY.

THOUGH not as yet officially announced, it is nevertheless very generally understood in the professional circle that an election of *four* additional architect members of the Royal Hibernian Academy has *de facto* taken place, and awaits ratification by the Royal Commissioner; we therefore conceive that we may, without transgressing prudential bounds, publish the names of the new members, at least as report has furnished them to us—viz., Sir Thomas Deane, Charles Lanyon, Patrick Byrne, and William Murray, who together with the present academicians, J. J. M'Carthy, and John S. Mulvany, will constitute the authorized quorum of six. We trust that one of the first palpable benefits resulting from this acquisition to the academy, will be a more creditable display in the architectural department at the ensuing exhibition.

MUNICIPAL TAXATION.

IN the course of an able statistical resumé on this subject by Alderman John Reynolds, J.P., at a meeting of the Corporation on the 24th ult., the following figures were quoted respecting the overtaxed state of the city, and for which every citizen and householder should feel grateful to that energetic member:—

"The gross sum assessed last year was £170,244; made up thus – The north sewer rate, fourpence in the pound, £3,583; the south sewer rate, £5,176; police tax upon a valuation of £525,627, and £241,459 of rural valuation, at 8d. in the pound, £25,569; grand jury cess, upon a gross valuation of £519,947, £30,330; poor-rate on the north side is £15,737; supplemental do., £5,554; and on the south side, £17,337. Improvement rate, 2s. in the pound, amounting on a valuation of £508,722 to £50,872. There was also a sum for public buildings; and the pipe-water rent was £13,201; making a total as above stated. He had no reason to suppose that it would be less in 1861; on the contrary, he believed it would be *more*."

The speaker suggested, for the *ninth* time, that a memorial be submitted to his Excellency to use his influence with Government "that such local charges as carriage-rents, pawnbrokers' licenses, fines and penalties, should be paid into the borough fund in aid of paving, lighting, and cleansing, instead of being paid towards the support of the police force, over which the municipal representatives had no control."

DUBLIN, "THE MADDEST CITY IN THE WORLD."

AT the meeting alluded to in above paragraph the same speaker declared that he had made a curious calculation showing "*Dublin to be the maddest city in the world*" (what a laugh for *some* people!) inasmuch as that the number of dangerous lunatic committals to our city gaols were in the ratio of 1 in every 700 of the population, whereas those for the whole of Ireland were 1 in 2,690 – the former being an average *four* times greater than the entire country; further, that the sanity of the Drogheda folk must be considerably in advance of the Dubliners, as the per centage of lunatics is immensely less in the former than in the latter instance. The returns for Dublin are as follows:—In 1856, 46 males, 57 females, total, 103. In 1857, 52 males, 66 females, total, 118. In 1858, 59 males, 64 females, total, 123. In 1859, 50 males, 74 females, total 124. The total number of both classes being 468. Of this number 155 males and 113 females were removed under the Lord Lieutenant's warrant. Of the 468 there were 375 committed from the city alone, the remaining 93 being country cases; and, the alderman remarked, considering that the total number of commitments in Ireland as dangerous lunatics during the four years mentioned appeared from the inspector's report to be 2,416, it should be admitted that the proportion for Dublin was something monstrous.

The approaching election of one member to the greater and one to the lesser dignities of the Royal Academy is occupying the attention of the art-world. Among the names of the Associates mentioned as likely to be raised to the full-blown honours of R.A. are those of Messrs. Boxall, Millais, Egg, and Pickersgill, but it is tolerably certain that the first-named gentleman will be elected. Mr. Faed will probably be the new Associate. It is also said that Baron Marochetti will be elected the Associate sculptor.

ULTIMATUM OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT length the parent professional Institute has arrived at an affirmative decision on the long-vexed, but too long-postponed question —"Should an architect be diploma'd;" and relating thereto, the following resolutions were passed at a recent special meeting:—

Proposed by the chairman, M. Digby Wyatt, Esq., V.P.—"That the examination be open to all members of the profession, and that candidates not members of the Royal Institute of British Architects do produce a recommendation signed by three members of the Institute, one of them being a Fellow, and subscribe the declaration as to practice, which is signed by members of this Institute."

Mr. George Godwin seconded the motion. Immediately upon this Mr. J. W. Papworth moved, and Mr. Robert Kerr seconded, an amendment—"That this Institute, by the publication of the resolution of the 25th of June, 1860, and in the circulation of the propositions submitted by the Council at that time, having to the utmost of its power ascertained the views of the profession thereon, and having taken into consideration the replies forwarded by various societies, to which the circular of the Institute was sent, does, in conformity with the wishes expressed in those communications, take upon itself the labor of instituting an examination tending to promote a systematic professional education."

In the course of a prolonged conversation a number of amendments were proposed, discussed, and withdrawn.

Eventually the motion was laid before the meeting in the following shape:—"That the examination be open to any British subject making such declaration of his intention to follow the profession of civil architecture as may be determined by the Council, on producing a recommendation from three members of the Institute, one being a Fellow."

The Chairman moved, and Mr. Penrose seconded, a resolution to the purport—That the Council be empowered to carry the preceding resolution into effect.

Mr. Robert Kerr moved, and Mr. Burges seconded, an amendment:—"That the Council be instructed to proceed towards the preparation of a *curriculum* and bye-laws, and be recommended to appoint a committee to this end, and to report to a general meeting."

Mr. Godwin suggested that the motion should be withdrawn in favor of the amendment.

This having, by leave of the meeting, been done, the amendment became a substantive motion, and was carried *nem. con.*

Another meeting of the Institute took place on the 21st ult., Mr. Godwin, V.P., in the chair, who announced that the discussion relative to preservative stone processes was fixed for the 28th; and stated that the three committees appointed by the council were as follows:—for "professional practice," for "the library," and to inquire into "construction and materials," briefly explaining the objects of each. Mr. Lewis read the substance of two papers by Mr. Hawkes, "On the Transverse Strength of Bricks," and "On the Expansion of Brickwork in a Furnace Chimney;" also called attention to some specimens of mosaics from Murano and Palermo, which Mr. Penrose proposed to apply to the pendentives of the dome of St. Paul's Cathedral; also to some specimens of paper with a pressed pattern (resembling leather work), by Messrs. Scott, Cuthbertson, and Co., of Chelsea, which was hung like ordinary paper, and then received two coats of size and two coats of paint; and to some patent bitumenized pipes for the conveyance of water, gas, and drainage, and which was intended to be substituted for those of cast iron. They were made of layers of course paper, and had been successfully introduced in France, Spain, and Italy. He likewise brought under notice specimens of a new material resembling marble, by Mr. E. J. Bridell, and which admitted of elaborate mouldings and ornamental forms An animated discussion took place, in which Messrs. Jennings, Rickman, Barry, Dines, C. H. Smith, and others took part.

Some very interesting mosaics from Carthage have recently been deposited in the British Museum, but have only been partially displayed to the public.

Mr. G. F. Train recommends for railway carriages during frosty weather, an American railway wheel of peculiar construction.

DUBLIN MECHANICS' INSTITUTION.—Report read at annual meeting on 21st ult., showed that the institute is in a healthy condition, contrasting favourably with former periods, when the numbers were much greater; also an increase in the number of library readers, a small amount remaining on liability sheet, a marked improvement in the fundamental classes, the success of the experiment to dispose of life members' tickets by lottery, &c., &c.

IMPORTANT DECISION AS TO ARCHITECTS' FEES.

Wylie v. *Willmer.*—Plaintiff is an architect and parish surveyor for Liverpool; Defendant, the proprietor of the *Liverpool Chronicle and European Times.* Action brought for £20 (5 per cent. fee) for finding a plot of ground and building in School-lane, and a further sum of £158 15s. for plans, &c., for a building thereon. The learned Assessor, in summing up, said—

Mr. Wylie is an architect, and he brings his action to recover £158 15s., which is a commission at the rate of 2¼ per cent. upon £6,350, being, as he states, the estimated value or cost of the erection of a building, the plans and specifications of which, pursuant to the instruction of the defendant, he prepared; and his right to recover depends upon the question of what the contract was between the plaintiff and the defendant. Gentlemen, if a man goes to a machine-maker and says—"Make me a machine, or a steam-engine," *and if you can imagine such a thing as no directions being given as to cost*, of course, when the engine is built or the machine is prepared, the purchaser would be bound to take it whatever its cost was. But suppose he ordered an engine of 200 horse-power, and the machine maker prepared one of 400 horse-power, it would be monstrous to suppose that the man who ordered one of 200 horse-power should be bound to take the one of 400. Now, in the case of an architect, if an architect is employed to prepare plans and specifications for the erection of a building—I don't know what the course may be in every specific instance, but probably, generally speaking, when a gentleman wishes to build either a house for himself, or a warehouse, factory, or other building, if he employs an architect one would think he would tell him—"I want such and such a description of building, of a house, or factory," in order that the architect may know somewhere about the style and proportions in which to proceed. Very likely, generally speaking, they will know the probable amount to be laid out on the building; and it must make considerable difference whether £1,000 is to be laid out or £2,000. It would probably make a great difference whether it should cost £2,000 or £6,000, which is coming nearer to this case. Well, if the architect is instructed to prepare plans and specifications for a building, the cost of which is not to exceed £2,500, or thereabouts, a little more or a little less, he cannot expect to be paid if he prepares plans and specifications which are not applicable for such a building as that, but require the outlay of a sum considerably exceeding the limits of £2,500, because his employment was to do a certain work. He has not done that work, but other work. He can, therefore, only recover in case he proximates to the contract which he has entered into with his employer—that is, to do the work specified by the employer. Now, the plaintiff's case here is that there were no such limits at all given to him; that he was employed to prepare plans and specifications. He puts it, "Although I knew in the first instance, upon the communication taking place between us and Mr. Holme, that about £2,000 was the limit, yet that was for what was originally intended in the first plot." As you remember, two plots were specified as purchased from the trustees. This was the plot of lands upon which a building to cost somewhere between £1,500 or £2,000 was to be erected "But," says he, "the defendant came from time to time; brought rough sketches of plans, and altered the building, which originally was to consist of two storeys only and a cellar, to four storeys and a cellar, and made a totally different description of building from what was originally contemplated; and he never specified to me anything about a limitation of money, but went on making these alterations, which would necessarily, from time to time, increase the expense. I obeyed him; what I did was by his direction; I did nothing without him; and therefore I am entitled to recover." And he is quite correct in that; because, if it were according to the mode in which he puts it—if, although originally the party contemplated a building to cost £1,500 or £2,000 only, and afterwards Mr. Willmer, without placing any limits upon the amount to be spent, gave directions to the architect from time to time to alter his plans, to increase and expand them, in such a way as that ultimately the plans and specifications required the outlay of £6,350 at the very lowest, Mr. Willmer must pay for that, because it was his own fault in not limiting Mr. Wylie in the way in which he ought to have done. He cannot, therefore, turn round and say—"I won't pay for it, because it is not what I wish to have." But, on the other hand, if the case is as put by Mr. Willmer and Mr. Fraser, who is with him, "that originally I contemplated £2,000 to be spent, and distinctly told Mr. Wylie that that was my limit; and that afterwards when I wanted alterations to be made, I invariably" (and in that you have the evidence of Mr. Willmer and Mr. Fraser both to the same effect)—"I invariably told him that if the alteration would exceed, or render a greater expenditure of money necessary than my limit, I would not have it done"—then it is a very different matter. Upon one occasion Mr. Wylie said—"Well, it cannot be done for £2,000." Then said Mr. Willmer, "Well, I will increase my limit to £2,500, but within those limits you must keep." And Mr. Fraser corroborates him; and they both say that over and over again—Mr. Willmer says twenty times at least—they told him he must not exceed £2,500. Well, gentlemen, although it may be said you cannot arrive accurately at what would be the cost of erecting buildings according to certain plans and specifications until the quantities are taken out, yet it is obvious that any architect of skill and experience would have some general knowledge which will keep him within certain limits, and certainly he ought to know the limits between £2,500 and £6,350. One of the witnesses called for the plaintiff, Mr. Culshaw, said it is obvious he must have done so. Mr. Cunningham said, of course they cannot know it accurately, but they must know to a certain extent. Well, if Mr. Willmer and Mr. Fraser are correct in what they say, undoubtedly there were limits beyond which Mr. Wylie was not to go. Mr. Wylie did go beyond them; he prepared plans and specifications which are not of any use at all to Mr. Willmer; and Mr. Willmer is not bound to pay for them, because their being used in the way described by Mr. Howorth makes no earthly difference When Mr. Willmer ascertained that the cost would be so great, he was not bound to take them, if they were not according to contract. There is the case, upon the oral statement of Mr. Wylie and his son on the one hand, and there is the statement of Mr. Willmer and Mr. Fraser on the other. If you believe the plaintiff's case, the plaintiff is entitled to recover; if you believe the defendant's, the plaintiff is not entitled to recover. It therefore depends upon the view you take of the different parties. They are all in a respectable station of life; and it is difficult to say that either one party or the other came here deliberately to tell that which was untrue, and yet it is difficult to reconcile these two statements. On the 2nd of November, it appears, after the tenders are sent in, Mr. Willmer finds out the extent of it; and he writes this letter—and when I read the letter and Mr. Wylie's answer, I think you will have the whole case before you:—

"Dear Sir—Allow me to draw your attention to my having stated to you that I contemplated expending upon my proposed erection the sum of £2,000, which Mr. Samuel Holme in his letter (which you read) of the 17th of August last quoted, and when he so remarked that for so large an expenditure on a ground-rent of £170 per annum a 42 years' lease should be required.

"I mention this here to show you that my whole movement has been based upon that outlay.

"I admit that at a subsequent date I extended the sum to £2,500. Upon giving you instructions, I did so on the understanding that your plans and specifications should be executed for that expenditure. You may, therefore, judge my astonishment upon receiving eight tenders ranging from £6,850 to £6,843.

"Being placed in this very unexpected and *embarrassing* position, I consider it my duty, acting under the advice of my solicitor, to return to you your plans, and to state that any connexion with you in *this matter* ceases to-day.

"I am, dear sir, yours, &c.,
"To Mr. Thomas Wylie." "Edward Willmer.

Now the answer to that letter, in which Mr. Willmer refers to having originally told Mr. Wylie £2,000, and afterwards extended it to £2,500, which was to be the basis of the instructions given to the plaintiff—the following is the plaintiff's reply:—

"My Dear Sir—I have to acknowledge the receipt of your favor of yesterday, informing me that you consider it your duty, acting under the advice of your solicitor, to return to me my plans (for your intended building), and to state that your connexion with me in this matter ceases 'to-day' (yesterday).

"I presume that I must take this as your fixed determination, though I think you can hardly mean so, on more mature reflection: should I, however, be mistaken in this, I can only express my regret at your apparently hasty conclusion, which, if you intend it to be final, ought to be accompanied by the payment of the usual commission and fees for surveys, which, under the circumstances, I claim in full.

"I can, in justification of myself, show how your ideas have expanded from a mere workroom and office to a palatial structure of amazing extent, containing upwards of 400,000 cubic feet, lofty and imposing in appearance; but that of course is not now necessary.

"I am, my dear sir, yours, &c.,
"To Mr. Edward Willmer." "Thomas Wylie.

Well, the only remark I will make upon it is, that whilst replying to Mr. Willmer's letter, he (Mr. Wylie) does not say to Mr. Willmer—"You never limited me in the first instance to £2,000 or £2,500." He passes that by entirely unanswered. Whether it was that he could not answer it, I cannot say, but he does not make any comment upon it. Undoubtedly he comes into court to-day, and says on oath that such things never did take place. Well, gentlemen, you are to say, taking all these circumstances into your consideration, whether or not the contract was as stated by Mr. Willmer and Mr. Fraser, because, whatever work the plaintiff may have done, he is not entitled to call upon the defendant to pay for it, unless it is done pursuant to the contract which was entered into; and that contract, if it were of the nature pointed out by Mr. Willmer, was to prepare plans and specifications which would require an outlay of £2,500, or thereabouts. He has never prepared those plans and specifications, and is not entitled to be paid anything at all, because what he has done is utterly useless to the defendant. Upon the other hand, if you do not take that view, and are satisfied that the plaintiff is correct; that no limits were given to him at any time; that he proceeded entirely by the direction of the defendant; and that, in truth, this building grew out of a mere workroom into a palatial structure, without any fault of his own—then he is entitled to recover the amount of 2¼ per cent. upon the £6,350.

Foreman: A few of the jury wish to ask whether we have power to give a smaller amount to the plaintiff, upon the smaller sum.

The Assessor: I don't think you can. He is either entitled to recover for all the work he does under the contract, or not at all. His contract was to prepare plans and specifications According to the evidence of Mr. Willmer and Mr. Fraser, they were to be plans and specifications for a building not to exceed a certain sum; and if the defendant gets plans and specifications which would not enable him to build such a building as he required for that sum, he gets no value from the work which is done. If, on the other hand, the contract was as the plaintiff states it to be, and no limits were assigned, there is nothing to prevent his being entitled—in fact, it is admitted by the defendant he would be entitled—to the whole money; so that it is either the whole or none.

The Foreman said—We are agreed to find a verdict for *the defendant.*

COURT OF BANKRUPTCY AND INSOLVENCY.

In re J. H. Carroll—The bankrupt was a builder. The meeting was for the examination of witnesses with reference to securities which the bankrupt had given to the Messrs. Martin for advances made by them to enable him to complete contracts which he had on hands.

Mr. Heron, Q.C., appeared for the creditors; Mr. Martin appeared for the Messrs. Martin; and Mr. Rollestoue, Q.C., for Mr. Jones, the architect of the contracts.

The case was adjourned.

In re James Daly (an insolvent, formerly a miller at Mullingar).—The case came before the court on motion for reference to Chief Clerk to take an account of all moneys due by the deceased and surviving trustees of the partnership estate of the insolvent and John Smith. Insolvent and John Smith were partners in the building of a Lunatic Asylum at Mullingar, and in the year 1852, being unable to continue the works, transferred them to Messrs. Martin and Headech, who prosecuted the works until the latter portion of 1854, or beginning of 1855, when the trustees gave up the further charge of the building to the Board of Works. After referring to the facts of the case, his lordship said he had come to the conclusion that it would be a wilful waste of money and time to allow the official and creditors' assignees to commence the proceedings asked for.

INSOLVENTS.

John Lennon, Terenure, Co. Dublin, slator and contractor.
James Wilson, Belfast, machinist and brick manufacturer.

ASSIGNMENTS.

James M'Killen, Ballymena, Co. Antrim, carpenter and builder.

Coming Trials.—Amongst the cases for which notices have been served for Hiliary Term after sittings we observe those of Lynch *v.* M'Dermott (work and labour), Brady *v.* Martin (ditto).

NEW DRINKING FOUNTAINS.

In an early No. of last year's volume, we illustrated some designs for drinking fountains, suitable for erection in cities and towns, with a view of inducing our citizens to join practically in the movement, then and since on foot throughout the kingdom; and we have had the gratification to witness the salutary effect—at least in a degree—of good example, for this metropolis possesses now some few of these structures, and we have reason to hope for more. We notice one of pillar pattern with dog trough at base, on the "Coal" Quay, a well known resort for a class who, perhaps more than many others of the community, usually seek a more exciting beverage than *aqua pura*. However, it is refreshing to perceive that this valuable adjunct has been appreciated, and if it should, even by its presence, succeed in detaining *one* visitor *per diem* from entering the alcoholic depot, the philanthropic purpose of the promoters shall have been recompensed. We must, nevertheless, express a regret that in the majority of those *as yet* constructed, *art* and *utility* have not been combined, and the more so as there are few subjects that offer a wider field for originality of design and ornamentation of a city. An exception, however, to this stricture, has been erected near the junction of Beresford-place with Eden-quay, and inside the area surrounding the north and west sides of the Custom-house, midway between that building and the Northumberland Hotel. It is the gift of His Excellency the Earl of Carlisle, and is partly constructed of limestone and partly of Caen stone, with granite base. Cost about £50. Messrs. Deane and Woodward, architects; Messrs. Purdy and Outhwaite, constructors. The total height is about 10 feet to vane. The interior is fitted with a charcoal filter, and the slab seen at the rere is intended as a rest for burdens.

The mural fountain, also illustrated herein, has been constructed in Parkgate-street—near to the city entrance to the Phœnix Park—after a design by the same architects, and was likewise the gift of His Excellency, whose characteristic discrimination and truly eminent philanthropy most happily suggested the suitability of this site. The water is exceedingly pure, and passes through a filter similar to those used in London. Messrs. Cockburn erected the constructive portions, and Messrs. Purdy and Co., the carvings. Cost, about £50.

ULSTER BANK ARBITRATION.

The questions in dispute between the contractors (Messrs. Fulton) and the Directors of the Ulster Banking Company, relative to the newly erected bank at Belfast, and for which a sum of £4,068 balance is alleged to be due to the former for works executed, has been referred to arbitration by order of the Court of Common Pleas. Some difficulties arose as to the arbitrators, owing to the two gentlemen named in the contract having been subsequently in the employ of the bank, and again a third—Mr. Barre—having been a prominent competitor. Proceedings were, therefore, necessary to the appointment of new and independent parties. We learn that the gentlemen selected are Mr. Beard, of Glasgow, and Mr. Lanyon, of Belfast, with a Q.C. for umpire, for which Mr. Vance's name is suggested. Our readers have been already made fully aware of the particulars and features of this important structure, which required a more than ordinary amount of skill to bring it to a successful completion, and as the several departments of work therein have been (we believe admittedly) executed in a most creditable manner, it is more to be regretted that any obstacles to final adjustments of accounts should have presented themselves. They may, however, to an extent be accounted for by the fact, that there was *no specification*, but a substitute in the shape of approximate bills of qualities and agreement to remeasure the work after execution, and different modes of measurement and valuation having been adopted.

THE ARCHITECTURAL ASSOCIATION OF LONDON.

An ordinary meeting took place on 18th ult., M. T. Roger Smyth, President, in the chair. Allusion was made to the "architectural examination question" on the tapis at the Institute, and the chairman announced that the Polytechnic Institution had signified their intention of including architecture in their educational programme, thus, "to have three courses—one on the essentials of building, one on architectural character (the history and practice of Classic, Mediæval, and modern styles of architecture, with notices of distinguished architects and their works); and, thirdly, a course on modern practice." The register's report was next submitted and discussed, after which Mr. Arthur Allom read a paper on "The Battle of the Styles."

ILLUMINATING PLATFORMS AND VAULT LIGHTS.

In New York there is an extensive adaptation of a recently obtained patent for lighting subterraneous apartments under the pathways and roadways of thoroughfares, without in the slightest degree impeding the traffic. Within a certain circuit in any city the acquisition of so much additional space for cellarage, storage, &c., is a great desideratum, and the following is a sketch of the manner in which it is effected:—

The supporting beams and pillars are of cast iron, strengthened when necessary by wrought iron tension rods. Upon these, slabs of illuminating pavement are laid, the joints being staunched by bituminous cement, and the surface getting such a pitch, or grade, that it sheds water freely. The slabs of pavement are bolted on by ears to the beams, so that they cannot be started nor warped by any weight upon them. The lights introduced into these slabs are strong masses of glass, which fit as exactly as may be into the holes prepared for them in the slab where they are secured and rendered water-proof at the joint by a small portion of asphaltum, or some other bituminous cement. Where the vaults extend under the carriage way, it is found advisable, for the sake of deadening the overhead traffic, to turn small brick arches from one iron beam to another, the beams being made ⊥ shaped to form an abutment, from which the arches may spring. These arches being then coated over with asphaltum to make them tight, are covered with common pavement, like other parts of the road.

The illuminating platform supplies an abundance of light. The vault lights give sufficient in the lower depths to enable persons to see whatever is stored there; while by the ordinary appliances for ventilation an abundant supply of vital air can be furnished for the occupants or workers in those subterraneous apartments.

The light, cheerful covering, the absence of darkness, the airy, healthful atmosphere in the underground apartments formed by these cast-iron side-walks, form a striking contrast to the dark, dismal, gloomy, small vaults made with brick arches. The brick being small in size, the arches must necessarily be of small span and quick curvature; being absorbent of moisture, the vaults must be damp, cold, noisome; while the unfitness of such vaults for storing anything that would be injured by moisture, renders them almost useless, except to store fuel. On the other hand, with cast-iron side-walks, the vaults can be lofty, the height not being taken up with a thickness of brick or flagging. They can be made perfectly water-tight, for no water can pass through iron or glass, and the side-walk, together with the gutter, or kennel, are formed and connected into one waterproof covering, continuous overhead. The vaults can be made the full width of the house or lot, because the side-walk is supported upon heavy beams extending its entire width from the roadway to the house-front, not requiring any arches or other supports but their own strength, to uphold the flagway, which itself is a platform of iron and glass, light, strong, and waterproof.

The surface of the cast-iron pavement is roughened in a very efficient way to prevent slipping. Vaults so constructed are estimated at an annual value of 100 dollars per annum: we should suppose that in London they would fetch considerably greater rent.

A movement is on foot for the opening of the Glasnevin Botanic Gardens on Sundays. The promoters allege that "the beautiful Botanic Gardens at Kew, near London, are open every day, and so great has been the pleasure afforded by this wise concession to public opinion, that a number little short of half a million of persons visited it during the past year, immense numbers going there on Sunday, and not a single instance of injury of any consequence is recorded. Gardens in many other places in England are similarly accessible, and with like good results. Our own Zoological Garden gives like encouragement for affording every innocent means of recreation to our fellow-men. Ever since its council came to the wise resolution of opening it on Sunday at the small charge of one penny, it has afforded delight to increasing thousands from year to year; and ample testimony is borne, in the annual reports of the society, to the admirable good conduct of the visitors, who need no police to make them well-behaved."

The Liverpool Graving Docks.—Instructions has been given to the engineer of the Mersey Docks and Harbour Board to prepare plans for a new graving dock with vertical or nearly vertical sides. It is to be 100 feet wide at the bottom, and 107 feet wide at the top, with centre and side blocks, similar to those of the new graving docks on the Cheshire side of the Mersey.

Co. Surveyorship, Westmeath.—The Lords Justices have been pleased to appoint to the surveyorship of the Co. Westmeath, James Alexander Dickenson, Esq., son to the late Lord Bishop of Meath.

DRINKING FOUNTAINS IN DUBLIN.

MESSRS. DEANE AND WOODWARD, Architects.

BIOGRAPHICAL SKETCH OF BRAMANTE D'URBINO.

THIS celebrated architect was born at Castel Durante (or, according to some accounts, at Femagnano), in the province of Urbino, about the year 1444. The family, of which he was a branch, was poor, though respectable, by whom he was designed for a painter: his early years were spent in the study of this art, but his taste and talents for architecture outran every other consideration, till at length he devoted himself altogether to it. He travelled first in Lombardy, and having made some observations on the cathedral of Milan, he went to Rome, where he executed some paintings for the church of St. John de Lateran, which are now lost. His great care was to examine and measure all the precious remains of antiquity, both within and out of Rome; he measured all that he could of the Villa Adriana, at Tivoli; and in pursuit of similar objects, went even so far as Naples.

This devotedness to his favourite science attracted the notice of many patrons of the fine arts, and among the rest, of Cardinal Oliviero Caraffa, who employed him to rebuild the convent della Puce, at Naples, which established his reputation. The work itself is not of the most exquisite character, but it procured him the title of architect to his holiness Pope Alexander VI., there being at that time no artists of superior talents in the papal dominions. The fountain of Trastevere, and another fountain, which formerly stood in the square before St. Peter's, were of his workmanship. He also had a considerable share in building the palace della Cancellaria, the church of San Lorenzo Damaso, and the palace of San Giacomo Scosciacavalli; all these, as well as the convent della Puce, above noticed, are built in travertine, on the outside; but their meagre style is a striking evidence that in the days of Bramante architecture was only reviving, and was not completely purged from barbarous intermixtures. In such an age the genius of Bramante could not but shine, and he retained his lustre, as being without an equal in invention, as well as in execution, till, towards the decline of his life, the superior powers of Michael Angelo Bonarrotti bore away the palm of science, and the voice of public applause.

When Julius II. obtained the papal chair, he appointed Bramante superintendent of his buildings, and employed him to execute his grand project of uniting the Belvedere to the palace of the Vatican, by means of a magnificent court. In his turn, Bramante engaged the pope in the favourite design of pulling down the church of St. Peter's, and erecting a new basilica, after the model of the Pantheon, on a scale that should astonish the world. With this view he made many drawings, and used great diligence to produce one having two steeples with the front between them, as may be seen on the medals struck by Corodasso, in honour of Bramante and his patrons Julius II. and Leo X. The plan was that of a Latin cross, and was well constructed, though of an unequalled magnitude. Three naves were formed by means of colonnades; the principal nave of very fair proportions, and the whole productive of the finest effect. The cupola had the same dimensions with that of the Pantheon; the external steps were also similar. Indeed the plan of the whole basilica bore a strong resemblance to the Pantheon, having eight piers, between each two of which were two columns, forming three openings or passages. This design being approved of by the pope, part of the old church was pulled down, and the foundation of the new structure laid, in the year 1506. The building was carried on with great celerity as high as the entablature, the arches over the four great piers were turned, and the principal chapel, opposite the door was erected, when death put an end to his labours, in 1514, in his 70th year. The continuation of this work was given to Michael Angelo Bonarrotti, who also did not live to see it completed. Bramante's successors made so many alterations upon his original design, that scarcely anything besides the four great arches over the tribune can be said to be his. His remains were interred in St. Peter's, and the solemnity was honoured by the presence of the papal court, and all the professors of the fine arts in Rome and its neighbourhood.

Besides the works above described, Bramante constructed a whimsical staircase, with the three orders of architecture, in the Vatican. The elegant circular temple in the cloister of San Pietro Monterio, though esteemed as one of his best performances, has many defects; for instance, the doorway cuts into two pilasters; the balustrade is a continued series of balusters without pedestals; and the ornament at the top of the cupola is clumsy and heavy. Out of the walls of Todi, Bramante built an insulated temple, encrusted on the exterior with white stone; the plan is that of a Greek cross, with a fine cupola in the centre; and the whole has an air of being the model of St. Peter's. In finishing the chapel within the basilica, he revived the use of the ancient stuccos. He made many designs of palaces and temples, both within and without the walls of Rome, and began the palace, which was afterwards finished by Raffaello, with columns of brick covered with plaster, then a new invention; but this edifice was destroyed to make room for the colonnade of St. Peter's; and the palace which he began for the Duchess Eleonora Gonzaga, wife of Francis Duke of Urban, was never completed, owing to the deaths of both duke and duchess.

AN ODE TO THE TURKISH BATH.

BY DR. HAUGHTON.

Soon in each town shall stately piles appear,
To show the hand of progress has been there;
Soon shall the Briton purchase *for a groat*
A bath which sets all other baths at nought,[*]
Where he can calm recline, walk, sit, or stand,
Waiting in turn the tellak's soothing hand,
From whence he comes divested of all care,
Bold to defy the keenest wintry air,
Strong as a lion, active as the roe,
He feels the love of man, yet fears no foe;
His pulse with double vigour bounding thrills,
With pure delight his heaving bosom fills;
His heart expanding sees the world grow fair,
Nor can behold the pain and woe that's there.
The car of progress flies with rapid pace,
And each great city strives to lead the race.
The STEAMING "HAMMAM," foremost in the van,
Gives Barter thanks, and says "Thou art the man!"
Who is so rude as would not Roman be?
Or who a craven, Spartan games to flee?
Learn of the ancients, cease your strife for wealth,
For nought can e'er avail you without health.
Turkey now gives you *what your fathers knew;*
Be ye as wise, unto yourselves be true;
Adopt the good, the evil cast aside,
And, above all, the heavy burden, pride.
Let the new era be envoked with joy,
And still let labour every hand employ;
The best good thing in this bad world receive,
Enter our gates and soon you will believe.
I am no prophet, yet I now declare,
A mighty change in England shall appear:
No more shall *poisoned blood* for poison call;
No more shall alcohol the mind enthrall;
Plenty shall reign, and fair Contentment smile,
And new enjoyments fascinate awhile;
And by degrees fierce passions shall abate,
Which now destroy a man, now curse a state.
When we discover where our evils lurk,
We in our turn shall thank the grateful Turk.

TIMBER.—The following is the note of goods sold at Messrs John Martin and Sons' wood sale, on the 17th ult.:—

82 gt. hund. of St. John's spruce deals, planks, and battens, from £15 7s. 6d. to £18 5s., average £16 17s. 6d., per 120 of 12 9 3.
30 gt. hund. of 1st quality Quebec Spruce deals from £13 10s. to £19 5s., average £19, per 120 of 12 9 3.
21 gt. hund. of 2nd quality Quebec Spruce deals from £16 15s. to £17 10s, average £17, per 120 of 12 9 3.
10 gt. hund. 1st quality Quebec pine deals from £28 to £29 per 120 of 12 9 3.
11 gt. hund. of 2nd quality pine deals from £21 10s. to £23 10s. per 120 of 12 9 3.
80 pieces crown Memel from 75s. to 77s 6d. per ton.
75 ,, red pine from 72s. 6d. to 75s. per ton.
35 ,, yellow pine at 52s 6d. per ton.
2 Lots Quebec birch from 72s. 6d. to 80s. per ton.
7 ,, St. John's birch from 72s. 6d. to 75s. per ton.
3 ,, board pine at 70s. per ton,
1 ,, oak at £6 per ton.
22 pieces ash, from 55s to 57s 6d. per ton.
45 wainscot oak logs from 7s. to 8s. per running foot.

VALUE OF OLD BRICKS.—We have had a curious illustration of the value of bricks, even old bricks, in this city lately. The houses which have been taken down in Jail-street to make room for the new jails, were built of bricks taken from some houses pulled down near Lady-lane, and these bricks were sold at *ten* shillings a thousand, and after having for years performed their part as good bricks and true in the houses in Jail-street, they were resold at *fifteen* shillings a thousand.—*Waterford Mirror*.

---

[*] This prediction is now more than fulfilled, as the Secretary of the Turkish Baths' Association of England writes to me that the cost of erecting some of the English baths is only about £10 or £15; and in some towns you can get a bath for 3d.

EXHIBITION OF THE FINE ARTS AND ORNAMENTAL ART, 1861.

A special meeting of the subscribers to the guarantee fund for carrying out the above project was held recently in the Royal Dublin Society House, for the purpose of appointing the finance committee.

Sir Richard Griffith, Bart., presided.

The Chairman said a report had been drawn up, giving some particulars connected with the projected exhibition. He called on Dr. Steele to read the report.

Dr. Steele read the report as follows:—

"A meeting of the subscribers to the guarantee fund has been called for the purpose of electing a finance committee, and it has been thought desirable to take advantage of the occasion to lay before them an account of the preparations which have been made, and of the plan of operation which it is proposed to follow, in order to ensure that the coming exhibition shall be worthy of the society and the country. The council of the Royal Dublin Society have entrusted the management of the exhibition to a general committee, consisting of the Committee of Fine Arts and of Manufactures, together with the honorary officers, and certain other members of the society. The general committee, while reserving to itself the supreme direction, has, for the convenience and despatch of business, been divided into four sub-committees —viz., of fine arts, of art manufactures, of building, and of printing and correspondence, whose several functions are sufficiently indicated by their titles. These sub-committees have been engaged in making the necessary preliminary arrangements, and are now in full working order. The exhibition will be held in the Agricultural Hall, into which the main public entrance will be direct through the great gateway in Kildare-street. Plans and estimates have been obtained for the gallery, which will be erected immediately, and will form a very material addition to our space. As the great spring cattle show will take place as usual in Easter week, the hall cannot be finally given up for the purpose of exhibition until April, when the requisite fittings, to be prepared beforehand, will be introduced, and the arrangements of the pictures and other objects will be commenced; and we shall be enabled, it is hoped, to open the exhibition on an early day in the month of May. It is proposed from time to time to have attractive musical performances of a high class. Advertisements of the intended exhibition have been issued, and will be continued; and we are sending out circulars inviting contributions of pictures and other works suitable for our exhibition; and we trust we shall be enabled to form a collection which will reflect honour on the public spirit of those who lend their valuable pictures and other precious works of art for the enlightening purpose of promoting art education, and of cultivating a refined and liberal taste amongst the people. There are many possessors of curious and valuable works of art, whom our circulars may not reach, or to whom we may not be able to make direct application. It is believed, moreover, that scattered throughout the country, and often in remote places, are many rare and precious objects well deserving a more public appreciation, but of whose interest and value the owners themselves are scarcely conscious. In pointing out to the committee the existence and locality of such specimens, as well as in using their influence to induce owners to become contributors, effectual assistance may be given by all who are interested in our undertaking; and on their cooperation the committee confidently rely. The finance committee, as representing those who have undertaken to make good the deficiency, should the receipts of the exhibition be inadequate, will exercise a general control over the expenditure, no outlay being incurred without their sanction. It must consist of members of the Royal Dublin Society, being also contributors to the guarantee fund. The guarantee fund now amounts to £9,055, and a correct list of the subscribers up to the present time is now submitted; but additional names may be still received.

"G. Sanders,
"Chairman of the Art Exhibition Committee.
"11th January, 1861."

The War-office has purchased thirty acres of land adjoining the Thames, below Gravesend, for the erection of extensive fortifications.

We learn from the *Kilkenny Moderator* that a bill "to authorise the mayor, alderman, and burgesses to make a general market in the city of Kilkenny, and for other purposes, is to be brought before parliament next session."

Mr. Joseph R. Kirk, sculptor, is engaged on a marble bust of Sir Leopold M'Clintock, R.N., the distinguished commander of the *Fox* in the successful Arctic expedition, to be placed in the museum of the Royal Dublin Society.

Mr. Malcomson has purchased Mr. Dargan's interest in the Foynes Railway for (it is said) £32,000.

THE FIRE-ESCAPE MOVEMENT.

Appropriately at this particular period, when public attention is so much directed to the necessity of ample facility being afforded for escape from the ravaging element, Mr. Moncrieff Wilson, Secretary to the Patriotic Insurance Company, prepared and read before the Statistical Society—affiliated to the Royal Dublin Society—an able and comprehensive paper, in which he advocates —"That a brigade for Dublin should consist of a captain and forty men, with eight engines, together with iron stakes, and the other requisites; that it would be desirable to have the brigade composed of police constables, the captain to be under the control of, and responsible to, the corporation of Dublin, or the Commissioners of Police; that a list of the names of all the men in the brigade should be published, with the rank, standing, and address of each; and that a copy of this list should be furnished to every policeman in Dublin; that there should be a central fire-station in College-green, and at least six other stations in different parts of the city; that the captain of the brigade should reside at the central station, and that three of his men should be constantly on duty there; that there should be a man on duty, night and day, at each of the other stations; that each fireman should have a board over his door with 'Fireman' printed in large letters on it; that fire-plugs should be set down all over the city, not more than seventy yards apart from each other; that on the wall opposite each fire-plug, a white board, black lettered, should be placed, indicating the exact distance of the plug from the wall; that the captain of the brigade should be held responsible not only for the state of discipline of his men, but also for the engines and other requisites being kept in the highest possible state of efficiency; that the captain of the brigade should report periodically to the corporation or Commissioners of Police as to the efficiency of the fire-plugs, especially during frosty weather, and that he should be held responsible for the fire-plug directions being kept in a legible condition; that at fires all engines, whether brigade or volunteer engines, and all men employed, whether brigade-men or volunteers, should be entirely under the command of the captain of the brigade, and implicitly obey his orders and directions; that at fires iron stakes should be used with a sufficient quantity of rope to afford a clear space in front of the premises for the exertions of the brigade; that when a fire occurs, the policeman on duty in the neighbourhood should instantly set off at full speed for the central fire-station, sending the first policeman he may meet to the nearest district fire-station; and that both men as they run should tell every policeman they meet where the fire is, in order that all the firemen may be duly summoned; that the captain of the brigade should have such control over the water supply, as at any moment, in any part of the city, to be able to command a sufficient supply for his purposes; that general orders for the guidance of the brigade and the information of the public should be published; that a certain number of the men belonging to the brigade should be formed into a fire-escape and salvage corps under the command of a sergeant, subject to the control of the captain of the brigade; and that the sergeant of the fire-escape and salvage corps should be sent for training to Liverpool or London; that there should be a fire-escape at each fire-station; that in each case of fire, the expenses connected with it should be borne equally between the owner of the property or the company with whom he may be insured, and the corporation or police; and adds, that the expenses of all indicated, after deducting sums recovered from owners of property and insurance companies, need not much exceed £1,000 a-year, also an inquest should be held on every fire."

TURKISH BATHS IN LONDON.

A favourable site for the first set of Baths has been secured in a central and populous part of the West End, and the directors expect to be in possession thereof in a few days. A plan of the building, drawn under the direction of Dr. Barter, has been submitted to the Directors, and arrangements are in progress for its erection, the success in the construction of the Dublin, and other Turkish Hot-Air Baths in Ireland, being a sufficient guarantee to the Shareholders for the perfect carrying out of the work. The building will contain twelve sets of hot-air baths, with divans, dressing-rooms, &c., fitted up with every convenience and comfort which modern refinement requires. It is intended to erect additional baths, within a short period, in other districts of London, when the shareholders shall deem it prudent.

COST OF THE FIRST SET OF BATHS.

Building	£15,500
Preliminary Expenses...	500
Furnishing	2,000
	£18,000
Add 10 per cent contingencies ...	1,800
	£19,800

THE NEW PRESBYTERIAN CHURCH AT SYDENHAM, BELFAST.

The beautiful design for the new church at Sydenham, in connexion with the General Assembly, and which is now in progress of erection, is by William J. Barre, Esq., the architect of the Ulster Hall, and includes a church with tower and spire, having sittings for a congregation of 500 persons, and schools (male and female), giving separate accommodation for 100 scholars in each. It is being erected on a well-chosen site on the Holywood-road, overlooking the bay, commanding an extensive view of the opposite coast, and will, when completed, from the novelty of many of its constructional features, as well as the elegance and picturesque beauty of its design, prove one of the most interesting of the many religious edifices of this town and its neighbourhood. The entire of the building, the tracery of the windows excepted, will be executed in brick, with dressings, weatherings, &c., of the same material. The walls of the church and tower will be built in red brick, with dressings of white, and further relieved by varying arrangements of other colours, in bands and devices. White brick, glazed on exterior surface, will alone be used in the spire. The church, which is 65 ft. 5 in. in length, is arranged with nave and transepts, having semi-octagonal ends. At the south-eastern angle of the nave is placed the tower, with an entrance and stair to a small internal gallery placed over the end of the nave. The principal entrance is in the eastern side of the nave by an open-timbered porch adjoining the tower, a second entrance being provided in the gable of the opposite transept. In the rere wall of the transepts is an arched recess, in the centre of this a door leading into a passage which communicates with the vestry and session-rooms, and with the hall of the schools. The school building projects from the rere of the transepts, and is two storeys in height. On the ground floor is the boys' school, 30 ft. by 21 ft. It is separated from the church by a hall, with a porch entrance for scholars; and in the hall rises the stair to the girls' school, which is immediately over that for the boys, and is of the same dimensions. The design is in the pointed style of the thirteenth century, but modified to suit the requirements of the present age and the employment of the materials adopted. The elevation facing the road will present the principal gable of the nave, with the tower and spire rising at one extremity. It will be divided into two compartments in height by coloured bands also marking the position of the gallery in the interior. The lower of these compartments is broken in the centre by a buttress, and pierced on either side by couplet lancet windows, deeply recessed. Over the buttress, in the upper stage, is a large lunar-headed window, with tracery, of five lights, while above rises the barge of the steeply-pitched roof, its apex terminating in a richly-floriated finial. The tower, which rises square in the plan to about the height of the eaves of the church, is buttressed at the angles. Over these buttresses it is weathered into octagon shape, and further up is lessened in diameter by two courses of weatherings in white bricks, with an intermediate dye of red. Above these weatherings rises the shaft of the belfry, pierced in each of its compartments by a lonored lancet light, and crowned by a deeply projecting cornice, from which rises the spire to a height of 79 feet from the base, its outline varied by trefoiled spire-lights, and terminating with a floriated iron vane. The western elevation will present a corbelled dormer rising into the roof, and lighting the gallery by a double lancet window, the buttressed side of nave, with its single-light windows, and the octagonal end of transept. In this transept end will be the second entrance to the church by a lunar-arched doorway, with deeply-recessed and chamfered jambs, while over in a dormer gable will be a spheric triangular window filled with traceries. Beyond this transept will extend the elevation of the schools, their lower storey buttressed and lighted by double and single light windows alternating, the upper having dormer gables pierced by couplet lancet lights. The eaves of the church will be composed of a moulded gutter supported on a course of corbelled brick. The elevation of the eastern flank will be varied from that of the west by the open timbered porch, and transepts gable being occupied by a five-light window with mullions and traceried head. In the interior the church will be fitted with open sittings wrought and chamfered, their ends cut to an ornamental shape and pierced by foiled and moulded sinkings. In the nave these sittings will be arranged in three rows—a central one of double width and two side ones of single—and will be approached by aisle passages four feet in width. In the transepts they will be arranged in two rows, one against each wall, with a broad central passage of six feet between. These passages will be laid with Minton's encaustic tiles in diamond-shaped patterns and in colours—buff and white alternate—while the seated portions of the floor will be laid with wood. Over the extremity of the nave will be placed the gallery, supported on columns, its front panelled and moulded, and projecting on richly traceried corbels. Immediately opposite in the transept wall is the arched recess before referred to, the head richly moulded and supported on jamb shafts, with floriated capitals and moulded vases. In front of this recess, on a platform of three steps, will stand the pulpit, which will be in the form of an open screen, with carved and traceried front. The walls of the church and schools will be plastered on the interior in fine grey stucco. The roof will be open-timbered, the rafters wrought, and stop-chamfered and panelled between, and will be supported on framed trusses resting on richly moulded corbels. The entire of the woodwork of roof and fittings will be stained and varnished. Mr. Edward Armstrong, of Belfast, is the builder. The new church will supply a want much felt in the rapidly rising suburb of Sydenham. The beauty of the design is in the highest degree creditable to the architect. Towards the erection of the building, Thomas M'Clure, Esq., J.P., Belmont, has most generously contributed the large sum of £1,000.—*Belfast News-Letter.*

PROPOSED JUNCTION OF THE DUBLIN RAILWAYS WITH A CATTLE DEPOT.*

On the north side of Dublin we have the Midland Great Western Railway, which forms with the Dublin and Meath running into it at Clonsilla, the entrance channel of the whole of the western and north-western traffic of the country. The Dublin and Drogheda Railway, commanding the whole of the direct northern traffic, crosses the Liffey branch of the Midland, and can be easily connected with it, by which means all the north and west of Ireland, besides the midland counties, will be enabled to deposit their cattle in the proposed market.

The Great Southern Railway, with its dependencies, commands the Dublin traffic of all the south of Ireland except the coast traffic to the county Wicklow. The junction I recommend to bring it into the Midland line would commence near the goods store at the King's-bridge station, would cross the Liffey by a viaduct, would have a covered way under the Phœnix-park only 600 yards in length, and would run through the townlands of Grangegorman to the point near the seventh lock of the Royal Canal, where the Liffey branch leaves the Midland Great Western Railway.

The position of this line in the vicinity of the King's-bridge is governed by the necessity for having the shortest possible tunnel in the best position under the Phœnix Park; but the actual point for leaving the Great Southern and Western Railway might be at or near Inchicore, if preferred by the company.

The junction I propose at the seventh lock would be at a point where the Midland Company possess a large area of land, and where extensive sidings are intended for the junction of the Liffey branch, and it is there that goods and cattle trains from the Great Southern and Western Railway should be brought to lie safely waiting for the engines of the Midland company to take them on to the North Wall, or, if it were so agreed upon, for the Great Southern and Western company's engines to take them on as soon as the line was ascertained to be clear. No other arrangement would be so safe or practicable. Besides cattle, there is an enormous traffic in goods of every description from both the great railways to the Liffey at the North Wall. This traffic amounts to at least 150,000 to 160,000 tons per annum. and is now carted through Dublin, to the great incumbrance of the streets, and at an expense of about £16,000 per annum.

In the case of coals, of which 28,000 tons annually go to the two railways, for their own consumption, there is breakage in loading and unloading as an additional inconvenience and loss. Neither is this important trade, as regards the public supply, half developed under present arrangements. The coal trade is in itself one, the development of which would be a blessing to the inland country, and it would be peculiarly beneficial to the railways by affording them return loads for their cattle-waggons, which now go back empty to the country.

The Liffey branch of the Midland line runs along the edge of the docks, half a mile long, of the Royal Canal, opening by tidal gates into the river Liffey. These docks, after some not very extensive alterations, would receive all the colliers for the railway business, and enable the companies to take the coals direct into their waggons. The same process would apply to other goods, in all cases where complete cargoes, or a large part even, were destined for inland consumption.

The railway companies themselves consume vast quanties of heavy goods, such as iron, timber, coals, and other stores, and it would be a great advantage to them to have a connection with the Liffey by rail, were it only to save the painful transit of boilers, locomotive engines, and rolling stock made in England, and dragged by long teams of horses from the Liffey through the streets of Dublin to their termini.

---

* Extract from the report of George W. Hemans, Esq., C.E., to His Grace the Duke of Leinster and the Right Hon. R. M. O'Ferrall, M.P.

I have not as yet alluded to the connecting of the Dublin and Wicklow Railway with the North Wall. This does not appear to me to be a matter of very great importance at present. Being chiefly a coast line, its trade in cattle to Dublin will not be very considerable, and it is well known that there is no goods traffic from the Kingstown and Bray section of it. Both the Harcourt-road and Westland-row termini might be connected with the Great Southern by a line along the banks of the Grand Canal, or more inland, parallel to the canal, if necessary. Mr. Blakiston, C. E., has proposed a direct junction from the Liffey branch to the Kingstown line by a tunnel under the Liffey. This would be a very complete and convenient mode of effecting the object, but I apprehend that for some time to come the cost of it would be considered an insuperable objection. Should the packet service from Galway to America increase as greatly in importance as it is hoped it will, there would no doubt be a great advantage in communicating without break of line from Kingstown Pier to Galway Pier; and this tunnel would in my opinion be, setting aside expense, the most direct way of obtaining it.*

The Liffey branch at the North Wall will have lines into the proposed cattle market on one side, and along the canal docks on the other side. Steamers to be freighted entirely with cattle from the railways may be run alongside the rail in the docks.

The discussion of the best mode of uniting the railways entering Dublin would be incomplete if I omitted to state, that it has recently been proposed to lay down *tramways* through some of the principal thoroughfares, especially those leading to Rathmines, but I am not aware whether the promoters contemplated eventually joining all the railway termini or the extension of their lines into the cross streets. Tramways, or street rails, have been laid down in nearly all the large cities of the United States. They unite the railways entering them, and carry on, at least, the passenger traffic of the principal thoroughfares; and I am sure they have, on the whole, been worked with considerable profit.

It is quite possible that in some of the main streets and suburban roads in Dublin, tramways might be laid down without difficulty, and be worked at a profit for passengers; and I am also of opinion that the termini of all the railways might be united by them; but even if this were accomplished in despite of existing difficulties, prejudices, and want of confidence in their value as a commercial enterprise, I am still of opinion that the junction line which I propose to run from the King's-bridge station of the Great Southern and Western Railway, to the seventh lock on the Midland Railway, at the commencement of the Liffey branch, and the branch line from the Drogheda railway to the terminus of the Liffey branch, near the North Wall should be executed, and for these reasons:—It can never be hoped that long trains of goods, cattle, or agricultural produce, intended to be shipped direct for England, can be carried straight on from the King's-bridge station or the Wicklow station through the streets of Dublin to the proposed New Cattle Market on the North Lots or the North Wall. Without going into details, it is sufficient to say that the obstruction such trains would cause to public thoroughfares, even at night, would be too great to contemplate; nor do I believe any traction would suit for them except the locomotive.

A NEW GENERAL CATTLE MARKET.

The description of the proposed market would be as follows:—A space of fifteen to twenty acres would be purchased. There would be a sufficient wall or enclosure all round, and the level of the space so enclosed would be brought up to a proper height by the surplus earth (of which there will be a large quantity) excavated in the course of the construction of the Liffey branch, and the proposed junction line between the Great Southern and Western and the Midland railways. The market for cattle, sheep, swine, &c., would therefore be at the same level as the rails of the Liffey branch, the wharves of the Canal Dock and the North Wall. Five acres would be covered in and systematically laid out in departments for cattle, calves, sheep, lambs, and swine. The whole area would be paved with the hardest bricks set in cement, with the proper channels for the urine and dung; part would be arranged in stalls, and part would be devoted to pens, but all would be covered and well lighted from above. Ventilation would, of course, be not forgotten, and receptacles would be placed at most convenient situations for the collection and removal of the excreta. Water pipes would be laid on from the third lock of the Royal Canal as well as from the Public Water Works, so that an amply sufficient supply would always be attainable, at a small cost, for complete purification by regular scouring with deck brushes after each market day. A small part of the covered space would be reserved for the offices of the salesmen and for banking purposes, and a comfortable house of refreshment would be erected in each corner, these houses would in such a situation, no doubt, let at very remunerative rents. Convenient standing room also under cover would be provided for butchers' carts. The whole market would, in fact, present very much the appearance of an unusually large railway station, covered with an iron roof supported on iron columns; the offices of the salesmen, clerks of the market, and banks being placed along one side, the gates for the admission of the animals from the railways and roads occupying another, while a side also would be devoted to the exit gates to the canal dock and North Wall; the fourth side would be adjacent to the slaughter-houses, through which there would be passages. I may conclude by stating, that the building would be fire-proof.

With reference to that portion of the above document which advocates the removal of the present market at Smithfield, Messrs. Ganly, Sons, and Parker, eminent salesmasters, have addressed the following to the Irish press:—

"Gentlemen—Although, as Smithfield salesmen, we have much to be affected for good or evil by removing Smithfield market, yet, in justice to the agricultural interests of Ireland, we most readily admit the necessity of some change to meet the wants of an increased supply of stock to our market, poured in by railway facilities from all quarters. No one who will for one day witness the thronged state of our present market, and the vile abuse given the cattle, forcing them through crowded passages, can reasonably resist the absolute necessity that exists for some remedy against it. We are also of opinion that a free, spacious and open market, where every man can sell for himself, or employ a salesman at pleasure, is due to the Irish feeder. *The place to hold the new market* is the all-important point to every one concerned. The North Wall, recommended by Mr. Hemans in his official report, is by no means the proper place, simply because there are no grass lands in that neighbourhood, and because the sale and shipping of stock differ in details from all other merchandise. Stock arriving at the North Wall on Tuesday or Wednesday, for seven or eight months of the year, for Thursday's market, should be driven back through the city to the grass fields available round Inchicore, the banks of the Liffey, Richardson's fields, Glasnevin, &c., to await the market day; they should then once more be driven back through the city to market. When sold, they should again come back through the city to grass, awaiting the shipping days—Fridays and Saturdays, when they should a fourth time pass through the city on their way to the shipping. The question is, why not establish your new market in the open fields midway between the termini of the Great Southern and Western and Midland Great Western lines, where the stock can go to grass and livery stables,—both of which are already established in those localities,—avoid long driving of the cattle, inconvenience to the citizens, increased freight on the owners, and serious abuse of their cattle? By holding the new market in that locality, the great majority of railed cattle by the two principal lines would be landed beside the market, and close by their grass fields. Those driven by road from the feeding lands of Ireland, it will be seen by the geography of the country, should arrive at those established grass lands without touching on the city. Thus the whole nuisance of cattle driving through the city could be avoided; for it could be no great additional trouble to shippers to drive their cattle from that locality to the shipping by the Circular-road from Phibsborough; or, even if they did drive through the city, it would only have to be done once, instead of four times, as already shown.

"With the project of a railway joining all the termini to the intended Liffey branch, as far as general merchandise is concerned, we have nothing to say or do; but we take this early opportunity of forewarning all whom it may concern that what suits merchandise, that eats nothing, is wholly inapplicable to stock, that must be fed seven or eight months in the year on pasturage, which, by the shortest process of selling and shipping, must be two and sometimes three or four nights on pasturage near Dublin. For the house-fed cattle there is already ample provision in the suburbs of the city adjoining this locality; so that general convenience seems to say, leave us in the fields.

"We do not hesitate to affirm that a share in a market at the North Wall for sale of cattle would be difficult to turn into cash; but why all the farmers' hay and straw would be hawked through the city to the North Wall, and back again for consumption, is what we cannot see the utility of. If it shall so happen, the sooner a new Carlisle-bridge, of treble its present breadth, is built, the better for the public. We write principally for the sake of our agricultural friends, to whom we are so deeply indebted for many years' patronage; but it may not be amiss to say to our fellow-citizens, keep the cattle, pigs, loads of straw and hay, &c., outside your city, if you wish to have a clear pass, and avoid serious obstruction."

---

* A steam ferry across the Liffey at or about the same point has been talked of, but this, for many obvious reasons, I consider quite inadmissible.

A NEW PAINT.

Being in Paris last autumn on a short professional tour, I sought for any thing that, within the architectural circle, might appear new, or even applied in a different manner than with us at the present time. Whilst descending the staircase of my hotel I was much struck with the appearance of the treads of the steps. I found on examination that the strings were painted and grained in the usual manner, but that the treads and risers were covered with a thickish coat of some hard mixture, having rather a glossy surface and somewhat of a yellowish orange tint. This was laid on each side of the steps—carpeting occupying the centre part as usual. The top water-closet was out of order, and early on the following morning workmen were engaged remedying the defects, and I found it already painted with the peculiar coating I had noticed on the stairs. Not only were the seat and riser of the closet covered, but also the wall, to a height of about three feet; the floor also, which was of tiles, had the same preparation of it; all dry and comfortable to the touch. The same day, while going over the fine library of St. Geneviéve, and in the ground-floor rooms, those devoted to the manuscripts, I observed that the floor of tiles was likewise covered with a similar preparation, which had been put on some time; the recesses between the cases appeared nearly as good as when first done, but the passages were worn in some places quite down to the tiles. The attendant spoke much in favour of the cleanliness of the preparation, which he said was of a resinous character. I noticed that it was the same as that employed at the hotel, but could not obtain from him any further information respecting it. Since my return home I have endeavoured to gain some knowledge of the material from those more conversant with French productions; but it is only very lately that I have seen a notice of this "new paint," described in a public journal, and as I am sure the merits of it are not publicly known, I have ventured to submit my knowledge of its use for the benefit of your readers.

This new vehicle dries, it is said, as rapidly as glue, and is as supple and solid as oil. It is composed in the proportion of 10 lbs. of purified yellow wax, 10 lbs. of linseed-oil, 8 lbs. of spirits of turpentine, and 5 lbs. of common resin. The wax is dissolved separately in the linseed-oil, and the resin in the spirits of turpentine, by heat, and are subsequently intimately mixed, when they form a pasty compound. In this condition it may be employed as a *priming*, being nearly *colorless* after application. When it is to be used as a vehicle for color, the pigments, ground up with oil in the usual way, are added in the proportion of one-third of the volume of the vehicle, and then spirits of turpentine in quantity sufficient to produce the desired amount of liquidity. So soon as the turpentine has evaporated, the coat of paint will support rubbing, if not too hard, without damage; but it takes a long time to become *completely* hard.

For this information as to the formation of the compound, I am indebted to the *Building News*, and perhaps should not have felt so interested in it, but for the practical knowledge gained previously. I did not see any use of it out of doors, but should imagine from its composition that it would withstand the effects of the weather; nor am I at all able to give any criterion of the expense in comparison with our usual painting. As I before remarked, it is laid on thick, say about one-sixteenth of an inch, or somewhat less, and for two at least of the purposes above mentioned, I should expect that the cheapest mode of completing the work would have been preferred; if so, this would of course be in favour of the "new paint."

There did not appear to be any smell such as is always given out by the common paint, and it was done in one application, whereby the household was relieved of the well-known disagreeableness attendant on two or three coats, and the stickiness whilst drying during the next three, four, or more days, according to the weather. Perhaps some of your "painter readers" may be inclined to try the recipe given, and report the result in your journal. I much regretted that the few days' stay in Paris prevented my giving more attention to the subject, but its being a first visit, with plenty to look at in a few days, must plead my excuse.

I am sure it is worth a consideration by the architect, even in these days of "no shams," for there are many occasions when such a preparation would be invaluable, as for floorings, covering old woodwork, &c.; and probably its colorless quality would render it applicable in cases where outside work was necessary to be protected from the weather, and yet where it might be desirable to exhibit the material itself.

W. P.

North of Ireland Railway Bills.—In the list of railway bills for next session we find the following from the north of Ireland:—Banbridge Extension, Enniskillen and Bundoran, Londonderry and Lough Swilly, Downpatrick and Newry Junction, Dublin and Antrim Junction, Portadown, Dungannon, and Omagh Junction.

Correspondence.

BUILDERS' TENDERS.

TO THE EDITOR OF THE DUBLIN BUILDER.

Sir—Thanks to your very useful publication, an initiative has been assumed in the matter of supplying bills of quantities, and checking to some extent the extravagant differences which occur in tenders; indeed I often thought you should have made a stir in this matter before, but better late than never. It is really monstrous the expense I (and of course every one like me) am put to in supplying estimates. I am frequently called upon by architects to send in proposals for works which it afterwards turns out are never executed; and if I am busy I must employ a surveyor at considerable cost, because without giving offence and losing the chance of future patronage, I cannot refuse; but how many builders are there who cannot take out quantities at all, and who are in every instance obliged to be at the expense, which is only occasional with me, or tender by guess, as you have described? Surely it is not too much to ask, if either information is wanted, or a building really intended, that it is done without serious cost to the party supplying it. In numerous instances in private practice, estimates are called for merely for the purpose of cutting down the price (if he will submit to it) of the builder intended to be employed; and here where a direct saving is intended to be effected, it is rather hard that I should be made the medium of reducing my brother builder to a low profit, at an expense of several pounds to myself. Some of the architects, I fear, will not go the whole hog with me in this, as I am convinced the juniors frequently inform their patrons that a building can be erected for a sum much beneath its value, and they are not anxious to go into detail, fearing it would then come to too much money; but this is really very foolish, and I wonder these young men would not foresee the consequences to themselves—the buildings, in many cases, left unfinished, a large amount of annoyance produced to all parties, and an injury done to the fair builder, who would have taken the work at a reasonable profit.

It is hard to change people out of old practices. I am getting old now, yet I hope to live to see the day when supplying bills of quantities to builders will be the rule and not the exception.—Yours, &c.,

A Builder.

A subscriber in the south of Ireland writes as follows with reference to the leader on "Builders' Tenders" in our last impression:—"I am frequently obliged to incur much trouble and expense in making estimates of buildings that are never carried out, or the plans changed. I have made *three* for a Roman Catholic church in Co. Kerry, and *three* for an addition to a marine villa in same place, according to plans by a London architect—that is, six tenders for *two* works for *one* person! Of course the architect must be paid for making new plans and altering others, and why should not the builder ask for some recompense for enlightening the proprietor?"

COMPETITION ESTIMATES.

TO THE EDITOR OF THE DUBLIN BUILDER.

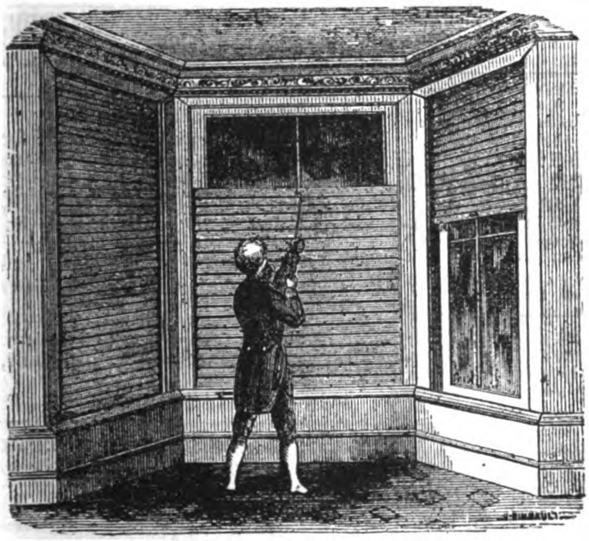
Sir—Building is a noble profession if properly attended to, and one of which all in connexion with it might feel justly proud. But there are so many drawbacks, or what I may call grievances—many of our own creation—with which the builder who intends to act fairly has to contend with, that I am often inclined to throw my avocation aside in disgust. In your last No. you have taken up a subject of much moment, and one which indirectly affects the entire machinery of building—namely, the preparation of estimates for competition. There can be nothing more annoying than after having spent possibly a week in carefully preparing an estimate, and when you have sent in your proposal to find some reckless, hair-brained fellow has been declared the contractor, at a sum little more than half what you well know to be a very moderate and scarcely remunerating price. Although this generally finds its level within a short period, it effects an incalculable amount of injury: depriving the fair builder of his business and connexion, and having him set down as monstrously high in his charges. "I would never employ," said the proprietor of a monster house to me one day, "any but the builder whose estimate was lowest; because, in the event of extra work, the others, I am convinced, would lay on in proportion to their respective amounts." But little did this gentleman know the contrary would be the fact, and that the highest tender could often be the cheapest bargain in the end, as I am positive he has since found out frequently to his cost. But this system is never-ceasing and continuous, as no sooner is one mushroom striken down than another rises in its place; while it sometimes happens these people fare better than honester folk, as by some hook or crook they manage to get out of their contract liability, and then the work is all measured, and the highest rates allowed, by which means their employers, who would not listen to any hints in the beginning, generally find they have to pay a pretty round sum for their whistles, and, to use a very homely phrase, "the d——l's cure to them." I often thought a remedy could be devised for this, and I think you are in a fair way of providing it. I am not one to blame the architects, because when a cheap John is recommended to their principals, they cannot—without appearing to have an object in view—say against him; but I think they ought in all cases to prepare themselves with an approximate value, so as to be able properly to pronounce upon the amounts, and the only way this can be done is by following your advice.—I am, Sir, yours,

A Subscriber.

Gaslights in Railway Trains.—A very successful effort has been made on the East Lancashire section of the Lancashire and Yorkshire Railway to light the carriages of a passenger train with gas. The invention is Mr. Newall's (the inventor of continuous railway breaks), and the gas is kept in a flexible receiver, in the guard's van. From the van iron tubes carry the gas over the tops of the carriages, the connexion between the pipes on each carriage being made of flexible tubing. From the pipes over the tops of the carriages short suspenders drop into each compartment of the carriages, to which are attached neat brackets and glass globes. Thus a flood of light by which passengers may read comfortably is obtained, and considerable warmth is imparted by the lamps, while all foul air escapes through the roof.

EDWARD J. HARTY, Chromo and Engineering Lithographer and General Draughtsman, executes in the best style, on the most reasonable terms, and with despatch, every description of Lithography, Chromo-lithography, and Steel and Copper-Plate Printing, Artistic or Commercial.

PERSPECTIVES in outline or Colour, and Paper Drawings generally, produced in a superior style, with despatch and economy. Application for Estimates will meet with prompt attention. Removed from No. 9, Dame-street, to No. 29 in the same Street (exactly opposite Crow-street).



CLARK'S

PATENT SELF-COILING REVOLVING SHUTTERS,

FOR SHOP FRONTS AND PRIVATE HOUSES,

THE MOST SIMPLE, SECURE, AND CHEAP SHUTTER EXTANT,

In Wood, Steel, or Iron, 2s. 6d., 3s. 6d., and 5s. per Foot super.

The Engraving represents the Shutters being opened without the aid of Machinery of any description.

VOL. III.—No. 28.

RECREATION FOR THE WORKING CLASSES.

THE boy Æsop is said to have humbled a venerable sage —descanting on loss of time occasioned by indulgence in play—by the simple theory "that the bow always strung soon becomes unfit for its purpose;" hence the moral is deducible that the faculties of man, be they the mental or the physical, engaged in active pursuits will ultimately lose their capacity if not refreshed by recreation. To no member of the community is an occasional respite from labour more essential than to the toiling artizan, who lives by the sweat of his brow; and when such combines the double element, its advantages are considerably enhanced. Education and the usages of modern society have taught him to feel that he has an opinion of his *own*, and moreover that he has a *right* to exercise it, as well as him to whom Dame Fortune has been more propitious in the distribution of her worldly favours, also that he and his master are alike creatures of the same species, and that the same Almighty Being presides over the existence and destinies of both. They have taught him to claim proportionate privileges for his resources, and be prepared morally to oppose monopoly or innovation.

A most laudable movement is being proceeded with in this city for the simultaneous elevation of the working classes on the social scale and contribution to their physical recreation, in the endeavour to induce the Royal Dublin Society to permit the opening of the Botanic Gardens at Glasnevin on Sundays. The following is an abstract of the particulars of an important meeting which took place on the evening of the 12th inst., in the Hall of the Regular Bricklayers' Society, Cuffe-street.

A deputation, consisting of Mr. James Haughton, Professor Hennessy, Mr. O'Mahony, and other gentlemen, with Mr. M'Evoy as honorary secretary, waited on the body for the purpose of urging co-operation. Each of the above-named addressed the meeting—which was somewhat thinner than would have been otherwise, owing to its being a festival night—to the following purport:—That as the Royal Dublin Society derives so much of its income through Governmental hands from the pockets of the masses, the claims of the latter to participate in one of the chief advantages of the institution, the Botanic Gardens—and, owing to their avocations, only available to them on Sundays—ought to be regarded; moreover that a precedence is afforded for the reasonableness thereof by the fact of the Queen herself having caused the Botanic Gardens at Kew to be opened, and that no detriment arose from the boon by misconduct or infringement of the rules.

Mr. Haughton observed that for three years an ineffectual agitation had been pursued to induce the Society to grant this privilege, that a majority of the members were antagonistic, and that *they*, individually, not the Society as a body, were to be censured. He also alluded to the fact, that the grant of a similar privilege by the Royal Zoological Society was the means of preserving that concern from decay, owing to failure of the funds, and that the conduct of the crowds frequenting the Gardens in the Phœnix Park was most praiseworthy. Should the Dublin Society still persist in refusing, the alternative was left to apply to higher quarters, and it should be resorted to. Mr. M'Evoy followed, and said that those who knew Lord Granville—to whom in his official capacity they should apply to compel the Society to acquiesce—knew that he was ever anxious to contribute to the public benefit, and would not turn a deaf ear to this request. Mr. Flood (one of the body) remarked that the Botanic Garden was a *bona fide* garden, and as such should be open to the public. He referred to the influence of botanical study on the arts of architecture, painting, sculpture, and others; to the origin of the Corinthian capital, suggested to the sculptor Callimachus by the Acanthus leaf; and to a circumstance which came under his own immediate observation of a friend and companion—a silver-chaser—stooping to pick from the roadside, during an excursion, leaves from which to model his foliage. All the speaker's remarks were peculiarly trite and suitable, evidencing a very uncommon amount of ability of which many in a much superior worldly position might be proud. He concluded by proposing a resolution declaring "the closing of the Botanic Gardens on Sundays to be a grievance which should be redressed."

Mr. O'Mahony reviewed the arguments of those opposed to the opening of the Botanic Gardens, and exposed their fallacy. He denied that the public of Dublin had ever been guilty of such an act of Vandalism as wantonly to injure or destroy any objects, whether rare plants or works of art, exhibited in places of public resort, and commented on the hypocritical plea which would fain deprive the public of healthful recreation on Sundays, calling on the tradesmen of Dublin to unite in obtaining what was sought for, not as a boon, but as a privilege and a right to which they were justly entitled.

Mr. Glynn moved the adoption of a petition to Parliament for the object above stated. It was seconded by Mr. Denis Byrne, and passed unanimously.

Professor Hennessy combated the objections which had been raised to the proposition of opening the Gardens to the public, and pointed out the public benefit certain to result from the concession of such a privilege to the citizens.

A petition for the above purpose was then signed by each member present, and several volunteered to procure additional signatures in the Mansion House Ward.*

Now we are not disposed to question the right of any person to do what he pleases with his own property—every man is the king of his castle—but we must in plain *parlance* ask can it be possible that in the midst of an enlightened body of universal renown—such as is unquestionably the Royal Dublin Society—there is to be found even a minority of members with "soul so dead" as to selfishly oppose the right of the poor man—to participate in an enjoyment paid for partially out of his own pocket. It is one of the many *privileges* of each member of that body to visit every day of the week, *Sunday included*, the gardens in question; moreover in the latter case they freely avail themselves thereof, introducing visitors and their families. "The glowing privilege of being independent" is indeed here truly but partially illustrated; however, we doubt not that the remonstrance now addressed so universally by the artizans, will convince the society of the injustice to the exclusive system.

---

* With the same object in view the deputation was received by the Regular House Painters' Society on the evening of the 13th inst., and the proceedings were somewhat similar to those above reported. A meeting is also to take place in the Tailors' Institute, with a like object.

INFLUENCE OF COLOUR ON THE MIND.

THE power of colour to produce strong emotions of the mind has been at all times recognised. Thus, when the sacred writer desired to raise in the mind a picture in the highest degree poetical of the Holy City, he represented that the building of its wall was jasper and its foundations as being garnished with sapphires, with chalcedony, emerald, and all other stones of resplendent colours; the gates were of pearl, and the streets of pure gold. No doubt the value and rarity of these precious substances were also calculated to excite the imagination; but their beautiful colours were evidently an important ingredient of the vision. Sometimes our admiration of an object is excited by describing it to be "like unto a jasper," or "to a sarden stone," or even to "a rainbow." The Bible is, indeed, full of evidences of the high appreciation of colour as a source of beauty and pleasure. In the Homeric writings also we may find abundant evidence of this natural and pervading feeling. Azure and vermillion are constantly used as typical, as it were, of regal splendor. No doubt every classic scholar can greatly extend these illustrations.*

---

* Mr. Sydney Smirke at the Royal Academy.

NEW FIRE ESCAPE.

An apparatus designed to supersede those now in vogue, for the above purpose, has been patented by Mr. James Magill, coach builder, of Mercer-street, in this city, at whose establishment a model may be seen. The lower portion comprehends an open van to contain fire plugs, additional ladders, ropes, &c., &c., suited to emergencies, fixed on ordinary carriage springs, and with *four* open wheels; on this is placed a platform with a central strengthening column, and four others at each angle sustaining a second platform, constructed at a higher level by six feet, and ascended by a ladder; this is about 13 feet from the ground, and intended for direct access to first floor windows, it is also protected by a surrounding safety handrail, it being the chief point of the brigademan's operations. Thence rises the escape ladder, 16 feet to the first joint, and connected with another folding length fitted with a crank free from friction, both being capable of adjustment to any angle by means of ropes passing over double sheaves, and communicating with a windlass near the ground which may be worked with facility. Through a pulley attached to the crank above alluded to is intended to pass the rope suspending the safety basket from the apex of the second ladder; and again to the bottom of the basket is attached another rope, by which it is guided with its living freight to *terra firma*. The ladders are capable, by a simple adjustment, of attaining any ordinary height, and when not in use can be doubled up and caused to fall back against the strengthening column. The chief points in this design which would seem to suggest a question, are its comprehensiveness and capability of locomotion with facility. Though we are not in a position to calculate precisely from the model —which is roughly executed—the weight of the actual apparatus, nevertheless it seems clear that without the aid of a horse, or at least a half dozen lusty fellows, its propulsion would be impracticable. This objection, however, may be counterbalanced by the fact, that such excitement generally prevails during fires that there can be no lack even of human aid sufficient; however, these and other considerations we leave to our readers' perception, and suggest to all those sufficiently philanthropic to appreciate the movement, and well-directed intentions of the designer, to go and judge for themselves.

THE INSTITUTE OF CIVIL ENGINEERS.

The inaugural meeting of this body, now affiliated with the University, will take place on the 19th inst., in the New Museum building: Sir Richard Griffith, Bart., presiding.

THE BAROMETER AS AN INDICATOR OF STORM.

At a general meeting of the Royal Irish Academy, held on the 11th inst., Rev Dr. Todd presiding, Professor Haughton expressed his belief that there was a great deal of misstatement as to the indicating properties of the barometer with regard to the approaching storm. It was certain that in the early part of last week information was telegraphed from Greenwich to several places that a violent storm was impending. This information was, no doubt, founded upon the descent of the barometer at Greenwich, The fall was seen in Dublin on Monday last, but it was a remarkable fact that the prophecy was not followed immediately by a storm. In fact it was not till five days afterwards that a storm took place. From the fact that the wind did not shift, he was of opinion that the late storm was not cyclon. In cyclon storms the barometer always fell a good deal. In the present instance, therefore, it might be stated that the barometer did not predict the aproaching tempest, and that metorologists were at fault. The Rev. Professor Galbraith said the subject was one of great scientific importance, and the extracts which he would submit to the meeting were taken from the Observatory in the Park of Trinity College. A fall in the barometer took place between ten o'clock p.m. on the 4th instant, from 29 deg. 72 mins. to 29 deg. 37 mins., and ten o'clock a.m. on the 5th instant. The glass kept rising from 29 deg. 03 mins. on the 5th instant, up to 30 deg. 32 mins. at ten o'clock p.m. on the 9th.

Mr Wilde said that amongst country people there was a popular notion that the barometer did not fall suddenly, unless with an "easting" in the wind.

THE ZOPISSA.

What is the zopissa which has formed the subject for so much comment recently at the Institute of British Architects? is a question frequently asked us. Mr. Tite, M.P., first specially introduced it to notice in his remarks on preservative stone processes, and read extracts from Pliny as to the use of pitch which had been scraped together from ships which had lain at sea, which was called *zopissa*, and which was thought to be better and stronger by reason of the greater capacity it had from being exposed to sea-water; but remarked that to say *zopissa* was useful at the present day for the preservation of stone, was to use a very hard word with a very unintelligible meaning.

Mr. Ashpital writes to the above body to the following effect, viz:—"First, as to the *zopissa*, which has been asserted to have been mentioned both by Pliny and Vitruvius, in connection with encaustic painting. I find no such mention. Pliny describes it in the words cited by Mr. Tite, as the scrapings of ships' bottoms, composed of pitch and wax, which had been softened, or purified by the action of sea water; and in another passage he says *zopissa* is useful as a species of poultice (malagmata) to disperse gatherings. The same definition is given in Dioscorides, and the same one in the surgical work of Paulus Ogineta. Vitruvius, on whose authority so much stress is laid, never even mentions the word. I cannot conceive a respectable man would willingly attempt to impose on the Institute by false quotations, and therefore fancy Mr. Szerelmey has confused the *zopissa* with *punic wax*, which last material *was* the vehicle of encaustic painting. This was wax purified by boiling it with sea water, or with nitre. The *zopissa* may be said to have been purified by sea water; but to suppose that pitch was ever a vehicle for laying on delicate colours is quite absurd. Fancy painting such delicate figures as those at Pompeii out of a pitch-pot!"

And Mr. Szerelmey.—"I fully agree with the opening speech of the talented member Mr. Tite, M.P., as regards his remarks on the term *zopissa*, a word applied by the Greeks to a certain process for preserving the timber of vessels, but I respectfully conceive that he has not gone far enough; the processes of both *zopissa* and encaustic, although ever tending to produce the same result, were of a very varied and undefined nature, artists modifying them according to their judgment, or as might be considered expedient for the occasion. The only *zopissa* spoken of is that for ships; no mention is made of the secret processes used by the great masters, nor is it ever stated that *zopissa* and encaustic were confined to fixing colours and indurating wood. As the term is used by me, it has a far more comprehensive signification, implying a preservative compound without reference to its being applicable to wood or stone, but embracing both. It includes the processes employed by the earlier Egyptians in preparing the groundwork for their monumental inscriptions, the mixing and fixing of their colours and their preservation; the preservation of the sycamore and other woods of which their coffins were composed, the solidification of their cements, the ground-work of their simply concrete or cohesive masses.

"I have not stated, either publicly or privately, that I used the process described by Pliny, but on the contrary have given it to be distinctly understood that my composition varied with the nature of the work. Both these processes for the present remain a secret, the only mode left me, as a foreigner, of reaping the fruits of my grievous toil and application to acquire it."

PRESENTMENT SESSIONS.

The next of these periodical meetings for County Dublin will be held as follows:—

Balbriggan, February 14th. R. A. Gray, Esq., Surveyor, Skerries.
Swords, February 15th. A. Tate, Esq., Surveyor, Santry.
Blanchardstown, February 18th. Same surveyor.
Raheny, February 19th. Same surveyor.
Newcastle, February 20th. Same suveyor.
Dublin, Sandymount, February 21st. R. H. Frith, Esq., Surveyor, 51, Leinster-road, Rathmines.
Dundrum, February 22nd. Same surveyor.
Tallaght, February 23rd. Same surveyor.
County at large, Kilmainham, February 25th. Same surveyor.

The Sessions to commence each day at eleven o'clock precisely.

Improvement of Kingstown.—The commissioners being of opinion that the proposed bill for transferring from the Grand Jury of the County Dublin to them the management of the roads and bridges in said town, will conduce to the health and convenience of the inhabitants, as also tend materially to the improvement of the town, and lessen taxation, purpose promoting same, and defraying the expenses of an act to authorize.

Sir W. G. Armstrong has been elected President of the Institution of Mechanical Engineers.

THE ROUND TOWER CONTROVERSY.—THE BELFRY THEORY EXAMINED.

BY RICHARD BOLT BRASH, ARCHITECT.

(Continued from page 414.)

It is highly improbable that the early Christians in this country would erect such a lofty, imposing and enduring structure as a round tower, for the mere purpose of hanging a bell in it. Various writers have been struck with the very diminutive size of the ancient Irish churches, particularly those erected before the thirteenth century. Any person who has visited Scattery, Iniscaltra, Clonmacnoise, Glendalough, &c., cannot fail to be struck with the humble size and pretensions of the ancient churches which at present exist in proximity to the round towers in those localities. A reference to the sizes of some of those structures will illustrate my argument.

The stone-roofed church of St. Molua, at Killaloe, which was the ancient cathedral of the diocese, and not older than the tenth or eleventh century, erected at the seat of regal authority, and under the auspices of a powerful toparch, is but 29 feet in length and 17 feet in width, a very humble unornamental structure.

The principal of the churches at Inniscaltra, and which was erected by King Brian Boroimhe, towards the latter end of the tenth century, is but 30 feet by 20, exclusive of a small chancel subsequently added; the more ancient churches are of much smaller dimensions.

Teampull Fineen, at Clonmacnoise, which is at present connected with the round tower called *Clogaus beg*, is but 28 feet 10 inches in length, and 14 feet 6 inches in width, not including a small chancel. Several of the churches at Clonmacnoise are still smaller.

The above-cited examples were churches of some consideration in their day; but the fact is, that the majority of the churches whose antiquity approaches that of the round towers are of much smaller dimensions, of mean aspect, and in very many instances of inferior workmanship to the round towers themselves—in fact generally so.

It certainly must obtrude itself on us as a strange anomaly, and a very unlikely procedure, that a young and struggling church should spend its means and energies in erecting these lofty, massive, and useless towers, while they built the temples of the Most High small, low, and mean. The bell-tower or belfry was at all times looked upon merely as an adjunct to ecclesiastical buildings, and so secondary a one that it was sometimes erected of wood, as I have before shown; and it was very generally the last part of the sacred edifice that was completed; as indeed it is at the present day. How many rich and capacious churches have we at this moment whose towers have never yet been built, owing to the want of funds; the people naturally completing first, that which was most important and necessary.

I shall advance another reason why the round towers of Ireland cannot be considered as belfries or as ecclesiastical adjuncts, and it is this: that, among all the religious establishments founded by the early Scotic saints and missionaries in foreign lands, not one of them at present, nor yet in memory or tradition, can show us a single instance of a round tower of the true Hiberno-Celtic type. Scotland, it is true, possesses towers unmistakeably of the above class; but they happen to be in that portion of the country which came under the dominion of the pagan Dalriads of Ulster, and whose entire topographical nomenclature is purely Irish.

I believe that Christian antiquity furnishes us with no case of missionary zeal parallel to that of the early Scotic (*i.e.* Irish) churchmen; their enthusiasm no dangers could affright, no hardships deter, no allurements seduce, no ridicule turn aside: they were eminently single-minded, their one object being to glorify God in the conversion of the heathen. These earnest men did not always wander about from place to place: they usually fixed upon some spot suitable for their labours, where there was a population requiring their teachings; in such places they erected, first a church, secondly a school; for the Scoti were then famous in Europe for their learning, and with them learning was the hand-maid of religion. These schools subsequently, upon the spread of Monachism, became monasteries, many of them remaining so to this day. For illustration, I would here refer to some of the most remarkable foreign establishments of the missionary Scoti.

In England the following were founded, between the fifth and eight centuries:—Lindisfarne, Lestingham, Ripon, Gilling, Whitby, St. Bees, Abingdon, Malmesbury, Glastonbury, and Burgh-castle. St. Aidan preached to the people of the kingdom of Deira and Bernicia. St. Fursa converted the East Angles; St. Finian the Middle Angles. St. Kieran preached the Gospel in Cornwall, and is still the patron of that country, under the name of Piran. In Britain also preached SS. Brendan, Maidoc, Senan, Molagga, Aed, and Colman. St. Maccaldus, of Down, was the first bishop of Man, in the fifth century. In Scotland, St. Columba founded churches at Iona, Mull, Tiree, Islay, Lewis, and Oransey; St. Donaan at Eig; St. Brendan at Seil; St. Blaan at Bute; St. Molaise at Arran; St. Maelruba at Skye. Melrose, Coddingham, and numerous other abbeys were also founded in that country by Irish missionaries. In Germany they founded establishments at Ratisbon, Wurtzburg, Erfurt, Constance, Nurnberg, Memmingen, Mentz, and Cologne. In France, Belgium, Switzerland, and Italy, innumerable religious houses were founded by them, between the sixth and twelfth centuries. It would occupy too much space here to enumerate them and their founders; those who are curious on the subject may consult Beda, Aldhelm, and Willebrod; and among the moderns, Colgan, Ussher, Ware, Lanigan, and Adamnan's *Life of St. Columba*, edited by Dr. Reeves. Now, I ask, is it not a very singular and significant fact, that if the round tower was a purely ecclesiastical structure, and a usual and necessary adjunct to our primitive churches, why is it that, among the hundreds of churches founded by the Scotic saints and missionaries in foreign lands, not one can exhibit a round tower, —no, not even in memory or tradition? Surely such zealous men as Columba, Brendan, Senan, Kilian, Kieran, &c., who had round towers standing in proximity to their own native monasteries or churches, would, if such were really essential ecclesiastical requisites, have introduced them in the various places where they preached the doctrines of the Cross, and founded churches. St. Columba has certainly been traditionally a great church-builder, yet we have no trace of a round tower in any of the numerous localities in Scotland where he is said to have built churches: to my mind, the argument is a perfectly conclusive one against these towers being of Christian origin or uses.

There is another fact fatal to the belfry theory, and it is this: that there is not a single tower that presents any original *preparation for hanging a bell.* Had the towers been erected for this purpose, the builders, keeping an immediate eye to their particular uses, would have made a solid and substantial preparation for suspending the bell, by inserting beams of durable oak, and leaving solid corbels of stone projecting internally as a foundation for the frame-work necessary for that purpose. Now, I have myself examined most of the Irish round towers, and have never found any such original preparation for the hanging of bells. In such of the towers as are at present used for belfries, holes had to be broken for the insertion of the requisite supports, and the violence requisite to accomplish this has in many instances been the cause of permanent injury to the structures. For instance, at Ardmore, where a bell was hung until recently, two rude rough gaps were made internally in the conical cap, into which a beam was inserted; the breaking of these holes has greatly injured the roof by displacing the masonry, while, to allow room for the bell to swing, the piers between the attic windows have been cut away and hollowed out: the whole operation having been productive of great injury to this structure. Any practical builder who has carefully examined the towers, cannot fail to be struck with the make-shifts resorted to in adapting some of them to the purposes of belfries. The holes for the timbers are invariably rough gaps in the masonry, not regular, neatly-built openings formed during the progress of the original building: this is also particularly observable in those towers in which floors have been introduced, where rude joist-holes are observable broken through the internal masonry.

In my former notes on the round tower controversy, published in the *Ulster Journal of Archæology*, vol. vii. p. 155, I made the following statement—namely, that "the first notice that Dr. Petrie has been able to produce, of what he designates a round tower belfry, is in the middle of the tenth century." I must partially qualify this assertion, by referring to a statement made by that gentleman in p. 384 of his work, respecting the erection of what he considers to be a round tower in the sixth century; it is not indeed designated in the original by the learned gentleman, a *clochteach*, nevertheless he conceives he has good grounds for supposing it to be a *round* tower. The authority cited by Dr. Petrie is *Adamnan's Life of St. Columba*, as given in Pinkerton's *Lives of the Scottish Saints*, taken from a manuscript, in the British Museum, of the twelfth century. The passage rendered into plain English is as follows:—"Chap. 15. Of the angel of the Lord that came speedily to the assistance of the brother, who fell from the top of the round monastery at Durrow. Another time as the holy man sat in his cell, engaged in writing, his countenance suddenly changed, and he cried out from his pure breast, 'Help, help.' Two of the brethren who stood at the door, Colgu, a son of Cellach, and Lugneus Mo-cublai, enquired the reason of this sudden exclamation. The venerable man replied, saying—'I ordered the angel of the Lord, who was here, to go speedily to the assistance of one of the brothers, who fell from the highest point of a great church [de summo culmine magnæ domus] which is now erecting at Durrow.' And the saint subsequently remarked, 'how great and surpassing is the speed of angelic motion, like, as I imagine, to the swiftness of lightning. The heavenly spirit who fled hence, when that man began to fall, arrived there as in the twinkling of an eye, before the body reached the ground, and by this means saved him from fracture or any kind of injury.'" Now, in the first place, I entirely dispute the authority of this collection of very apochryphal legends in settling a matter of fact of so much importance as the one under notice; the so-called Life, is no biography at all, but simply a collection of wonderful miracles and doings of St. Columba, given in paragraphs, without any sort of connection, and bearing ample evidence of their middle age origin. But, for argument's sake, admitting that this miracle was really performed, and that the original narrative has been carefully and truthfully handed down to us from the time of St. Adamnan, I submit that the terms used do not bear the construction put upon them by Dr. Petrie. I should state that the heading prefixed to the chapter is not found in some of the editions of this work, and as it is upon this dubious heading Dr. Petrie labours to establish the point at issue, he argues that the more ancient editions of Canisius, of Messingham, and of the Bollandists, are wrong in omitting it; and that, as the manuscript from which Colgan published his edition agrees with that in the British Museum in retaining the heading, it ought to be received as a portion of the original text of Adamnan: admitting, however, that this point has been scrutinized by the learned through the various manuscript copies of eight or ten centuries, and the point settled that the heading is original, we come now to consider its bearing upon the matter in question.

Dr. Petrie's assumption is, that the designation "de monasterii culmine rotundi," signifies a round tower, or that we should so understand it, or that such a building was thus expressed. I shall give his argument on the passage—"The real question is, what the author could have meant by 'de monasterii culmine rotundi.' Not, certainly, that the monastery itself had a round roof, because we know that the monasteries of those days were a collection of small and detached cells, each devoted to a single monk; and certainly not that the church itself had one, as it appears, from the notice in the text of the chapter, that the 'culmen' was that of the 'magna domus;' and besides, from the quadrangular forms of all the Irish churches of this period, they could not have admitted of a dome roof. But more than all, supposing it was from the roof of the church that the monk was falling, or from any other building such as we know to have existed in connection with the monasteries of that period, the tower excepted, where would have been the danger, to escape which, the miraculous interposition of an angel would be necessary? Surely not to prevent him from a fall of twelve feet or so, which is the usual height of the side-walls of the abbey churches of this period; nor from the roofs of either the abbot's house or monks' cells, which, though usually round, were seldom, if ever, of a greater height than twelve feet, and from which, having rarely upright walls, there could have been no serious danger in falling. In short the miracle, to be a miracle at all, requires the supposition that the round roof on which the brother was at work must have been that of a building of great altitude, and from which a fall would be necessarily productive of certain death. Such a building, in fact, as a round tower, which was the only one of the kind the Irish had, either in those days or for many ages afterwards." We here find our author's argument to be founded upon the assumption that by the "top of the round monastery," a round tower is meant:—what authority is there for such an assumption? None whatever; the passage is plain and simple—the round monastery. Surely, if the writer intended a lofty, slender, pillar tower, he would have conveyed his meaning in plain and suitable terms to designate such a structure. What, then, does the writer mean by the round monastery? Why, he simply means what he says, that this accident occurred in a monastery of a circular form. For the information of those not versed in the primitive ecclesiastical architecture of this country, I would explain to them that these establishments usually consisted of a number of circular stone-roofed cells, or *clochans*, each inhabited by a single recluse, with the church in the centre, or elsewhere; the whole enclosed by a circular wall or *cashel*, sometimes of uncemented masonry, sometimes of earth and stones, sometimes entirely of earth. An admirable description of those establishments will be found by the reader in Dr. Petrie's own work (p. 126), with illustrations of some of these circular stone-roofed cells. The heading of the chapter quoted then reads plain and simple enough: that the accident happened in a religious establishment of this description, designated *round*, either from the form of its wall of circumvallation, or from the general form of its buildings, or from both. But why use the phrase "the top, &c.?" Simply because it is an ordinary and usual mode of expression; thus, it is common to say, a man fell off the top of the barracks, or the workhouse, or the college, though there may be twenty roofs or buildings in any of them, the ordinary acceptation of the phrase being that the accident occurred from some of the buildings composing the college or the barracks, &c. But the heading of the chapter having thus stated where this circumstance did occur, the narrator in the relation expressly states the particular building from the top of which he fell, and he declares it to be the "magna domus." Now what building was the "magna domus?" in simple English, the "great house;" or, *par excellence*, the church. It was called *magna*, great, because of its superior size, its importance, its sanctity; the word *domus* is constantly and generally used to designate the sacred edifice. Parker, in his *Architectural Glossary*, at the word *dome*, says—"So much does the cupola prevail in the old churches, both in Italy and Germany, that the Latin word *domus*, or house, applied to that of worship, *par excellence*, is retained in the Italian appellation *duomo*, and the German one of *dom*, given to the cathedral of each city." Most of the ecclesiastical writers of the middle ages use the word *domus* for church; and indeed the mode of expression used in this legend smacks more of the middle ages than of the primitive times of St. Adamnan.

But Dr. Petrie further objects that it could not be from the church that the monk fell, inasmuch as the walls of the churches of these times were but twelve feet or so in height, and that there could be no miracle in saving a man's life in so trifling a fall. As to the exact height a fall from which will kill a man, I am not prepared to give an opinion; suffice it to say, I have known a man killed from a fall of six feet, and I have known men survive a fall of over forty feet. But if we examine the construction and size of the churches of that period, it will give us some insight into the probability of such an accident occurring. I will not here oblige Dr. Petrie to adhere to his statement (page 160 of his work) of the Church of Armagh, erected in St. Patrick's time, being 140 feet in length, and argue from thence what the probable size of the church at Durrow may have been; because I do not believe in that fabled church, nor in the monster lime-kiln built to burn lime for it. I will confine myself to matters within the bounds of probability, and which can be verified by existing examples. St. Cormac's chapel, at Cashel; St. Flannan's and Molua's, at Killaloe; St. Kevin's, at Glendalough, and others of that class, will supply us with a type of what the "Magna Domus" at Durrow was. Now, if we take one of the most moderate sized of those moderate churches, St. Kevin's Kitchen (so called), at Glendalough, we find that, though the walls are but 11½ feet high, to the eaves, the ridge of the stone roof is 32½ feet high, and consequently of an exceeding steep pitch; again, St. Columba's house, or oratory, at Kells, the dimensions of which are but 24 feet by 21 feet, is within a fraction of 40 feet to the ridge of the stone roof. Will Dr. Petrie assert that it would be no miracle for a man's life to be saved in falling from the "culmen" of such an edifice. I was on the ridge of St. Kevin's stone-roofed church at Glendalough, and I assure my reader that a tumble from it would leave very few whole bones in any one's body. I have now done with this subject. I hope I have given a fair and unstrained exposition of this passage, which indeed needs little commentary if we take its simple statement, as given in the original.

CHEAP CISTERNS AND FILTERS.*

INSTEAD of incurring the great expense of excavating wells, stoning them, and supplying expensive pumps for obtaining water for the ordinary purposes of a farm-house or barn, a much cheaper and more satisfactory arrangement will be found in the use of my cheap mode of constructing cisterns and filtering the water. A cistern of the dimensions that I shall describe will hold 1,000 gallons, will cost about £1 12s., and its capacity may be doubled for less than 50 per cent. additional cost. One of the size above-named will be found sufficient for farmers' families generally, and will insure soft water, which is rare in wells.

Stake and line out a plat near the building 8 by 18 feet; excavate this 1 foot in depth; then set the lines in 18 inches on all sides; then excavate all within the lines, or 5 by 15 feet, to the depth of 4 feet in the middle, making the middle level some 9 in. in width, sloping the banks on all the sides and ends to the lines last placed, which will make a section of the pit either way V-shaped, except that 9 inches of the bottom will be level.

In digging the banks use care not to disturb the soil not thrown out. When the digging is completed, plaster the bottom, the level part, with a good coat of cement mortar, and place a board on it to stand on to do the balance of the work, cutting the board in two equal parts before laying it on the mortar. This done, plaster the entire surface on the ground to the lines last named, then remove one half of the board and stand on the balance, and build a 4-inch brick wall across the pit, about the middle, laying the bricks, which should be soft (common salmon brick), in cement, but plastering neither side.

Lay the wall to the line, then remove the balance of the board, and put a coat of mortar where it lay. The cistern is now complete, save the covering; this may be done by laying plank over the whole bedding, then on the surface of the first excavation in mortar; or splitting logs from the woods and laying them flat side down, and closing the joints with mortar. The pump pipe should be laid into one end, and the leader pipe from the house gutter laid into the other, before it is covered. This done, return earth enough to cover the surface at least one foot deeper in the middle than the surrounding ground; level it off neatly, and sward it, and you have a complete filtering cistern for 8 to 12 years.

Sir Joseph Paxton writes to the *Times*, respecting the loose manner of contracting for the building of the Great Exhibition of 1862, which will cost about £250,000, and only a few days are allowed for tendering.

* *Architects' and Mechanics' Journal.*

THE RELATIONSHIP OF THE FINE ARTS.

On this subject Mr. Bell, sculptor, has been delivering a lecture at the South Kensington Museum, from which we quote the following remarks :—

" We must all see that the fine arts address us through our sympathies. Some, however, are more direct in this than others. Of these are painting and sculpture of the human form, for they represent our own race. Pope's well-known adage applies to this study : and painting and sculpture of the human form will always possess a more direct appeal to our feelings than any other branch of the fine arts. We may remark this in a building. No matter how admirable its structure and decoration, yet if it possess also paintings and sculpture of equal excellence, it is to them that the general eye will be attracted ; especially to the paintings which, in their art, leave nothing to be supplied by the imagnation. For this reason painting is ever the more immediately attractive of all the arts. Sculpture is more abstract. We may see the effect of this in any exhibition of the fine arts in any country. *Paintings* form the first attraction ; *sculpture* comes next ; then the *architecture ;* then the *decorations.*

" ' No one,' says Dr. Johnson, ' would write a book if he knew its leaves were at once to be scattered on the ocean ;' and who would elaborate a picture, or with many a studied stroke hew the statue from the block, if the moment of completion were to be the signal of their destruction ? In all our art works, we seek for sympathy. This is the hope, the dream, the prize of our efforts. No marvel therefore that this shews itself in the aim and direction of our higher art works, which use the form of man for their language. . . . .

" Thus it is in its movement amid the variety of surrounding nature, that the sympathetic key of art is at once responded to. It is the note starting from the human lips, which, ringing out amid the swell of instrumental music, thrills us more than all the billowy sounds beside. It is the voice in the storm that we catch with breathless interest, the footstep in the sand on which our gaze is riveted—the human form that steps out amid the works of creation and calls them all by name !

" It is in this respect that the arts of painting and sculpture possess their superior force. It is in their power in the direct representation of our kind that resides the immediate hold they have on our interest and sympathy. Nor can any form of mere architecture or decoration attract so *at once,* as the record of features which beam with intelligence, or the form which is the possessor and agent of that intelligence. In this walk of human representation these arts are directly of man and speak to man, face to face. With them, in this respect, architecture and decoration can by no means compete—which deal with parts of nature, animate or inanimate, which have less hold on our feelings, and thus, of the four arts, undoubtedly, painting and sculpture possess the more direct and shorter roads to our sympathy.

" It would thus seem, by this argument, that the pre-eminence rests with painting and sculpture over the other two arts. Architecture is an indispensable art—it is so directly useful. Painting and sculpture may be—architecture must be. The former were awhile in disgrace and lost to the world's sympathy. Architecture, like her sisters, had pandered to Pagan worship, and had built its temples for ages. But she was not overwhelmed by this obloquy like her sisters. She was too strong to go down before it. The world could not do without her, and her power survived almost without an interval. One of our finest styles, indeed, arose even amid the morning twilight ages—that of Byzantium—that of our own early church. Architecture was continuous, and moreover, after the lapse of some centuries, held out a helping hand to her sisters. She led them out of their captivity where, like the daughters of Israel in Babylon, they had hung up their harps and mourned ; after a while interceded with the world for their forgiveness, and by degrees restored them to their high places. And she had the power to do this because in her nature she is essential to us, and the world cannot do without her. Herein lies a great force and stability in her, on which a number of other forces are founded. We must have structures, and even as early records show, we must have them of various kinds. They should fulfil each purpose fitly : they thus become impressive and expressive in various ways. We may as well have them beautiful. It is at this point that architecture becomes a fine art ; before it was only a useful art. Yet have its most refined beauties the invaluable advantage of the substantial basis of the useful. It is on this solid foundation that this art rests. Loftily, airily, gracefully, and grandly as it may expand and tower into the beautiful and sublime, yet does its firm foot still rest on the rock of direct utility. This is a vast advantage, which in these practical days especially more than counterbalances the more direct appeal to our mind possessed by painting and sculpture. Painting and sculpture rest on our sympathies. Architecture greatly on our wants. Our sympathies may be in abeyance—our wants never. For their higher aspirations the three arts may tower together, but architecture is the base of the pyramid.

" But the fourth sister now claims our attention. In regarding her we must not forget our two-fold character. In her smaller province, Decoration, we may perceive, arises directly and chiefly from architecture. Ornament, so to speak, is the immediate parasite of architecture. It is the lichen that springs from it, a natural growth ; the ivy or honeysuckle that clings to its pillared trunk ; the mistletoe which buds out amid its branches.

" Advantageously as the sisters may all be seen together, uniting in practice as well as kindred in appearance, yet each has its individuality. Strong as the family likeness may be, still we may observe especial resemblances between some more than others, as we do in families. Thus we may remark that painting and sculpture seem much to group together, and architecture and decoration too have a similar affinity and disposition. We may notice one of the most striking of these points. Painting and sculpture both seek to represent the works of the Creator. Neither architecture nor decoration have directly this object. Decoration, to be thorough, must ever be more or less conventional ; if not in detail, yet in arrangement. The painter represents trees and flowers as they grow ; the decorator arranges a branch of foliage in a given line, and hangs his flowers in festoons. A similar conventionality or regular modification from nature distinguishes architecture. Deriving her styles evidently from natural objects, yet successful architecture is never the direct imitation of nature. The arch of Heaven may have suggested the dome; but the architect does not decorate it with the sun or moon, or portray a storm or sunset in it, but erects it with constructive embellishments of treatment which are without reference to the original type. The interlacings of a Gothic roof may have been suggested by the frondage of an avenue, and the pendentive ceilings of Alhambresque halls from the stalactite vaults of caves, cool and pleasant in a burning clime."

THE MYSTERIES OF SMITHFIELD.*

Smithfield professes to be a free market, and is, perhaps, really so for hay, but in practice it is not so for cattle. The houses surrounding the market are the property of butchers, dealers in the cattle trade, and others, who pay high rents and claim an area of the market square in proportion to the frontage of each house. On each area no one but the owner of the house or his tenant is allowed to place his beasts ; so that to any cattle owner desiring to sell in Smithfield there is no opening unless through the established agents, who consequently have the local trade as a monopoly in their own hands ; and who are, therefore, enabled to charge a commission of 2½ per cent. on all sales—certainly a heavy tax on so large a business. It is true that they are a very responsible and respectable body, and that sales effected through them are almost invariably safe, as they are liable by usage, in consideration of the commission on sales, for the amount of purchase realized to the proprietor of the cattle, who although he has not facilities to sell for himself, has at least the produce of his beasts in a manner insured from bad debts by the interposition of a solvent salesman between him and the actual buyer. The salesmen act also to a great extent as bankers, advancing money to grass farmers to stock their farms, and to the large class of cattle jobbers who attend the fairs to make country purchases, and who sell again in the Dublin market to the butchers. The same practice prevails through the same persons to a great extent as regards corn, hay, and oats.

OBJECTIONABLE SLAUGHTER-HOUSES.†

I must here refer to the extraordinary fact, that for the purpose of killing on an average so small a number of animals as 69 head of cattle, 274 sheep and lambs, and 165 pigs per day, no less than *one hundred and thirty-nine* slaughter-houses exist in this city. Three of these are public slaughter-houses, one being in Fish-lane, another in Cole's-lane, and another in Bull-alley. I have visited some of these slaughter-houses on business days, and regret to say that nothing can exceed the objectionable nature of the mode of operation, of the poisonous smells in crowded localities, and of the demoralizing publicity with which the whole affair is conducted. Animals are killed within sight of others waiting their turn, and blood is poured along the streets into the open gutters and sewers. All the other offensive relics of the slaughtering are scattered about in the lanes and yards.

I will only add, that there are, no doubt, some well-conducted establishments, especially amongst the pork butchers—for instance, that of Mr. M'Vey, the well-known provision merchant ; but these are only the exceptional cases—the rule seems to be as I have stated.

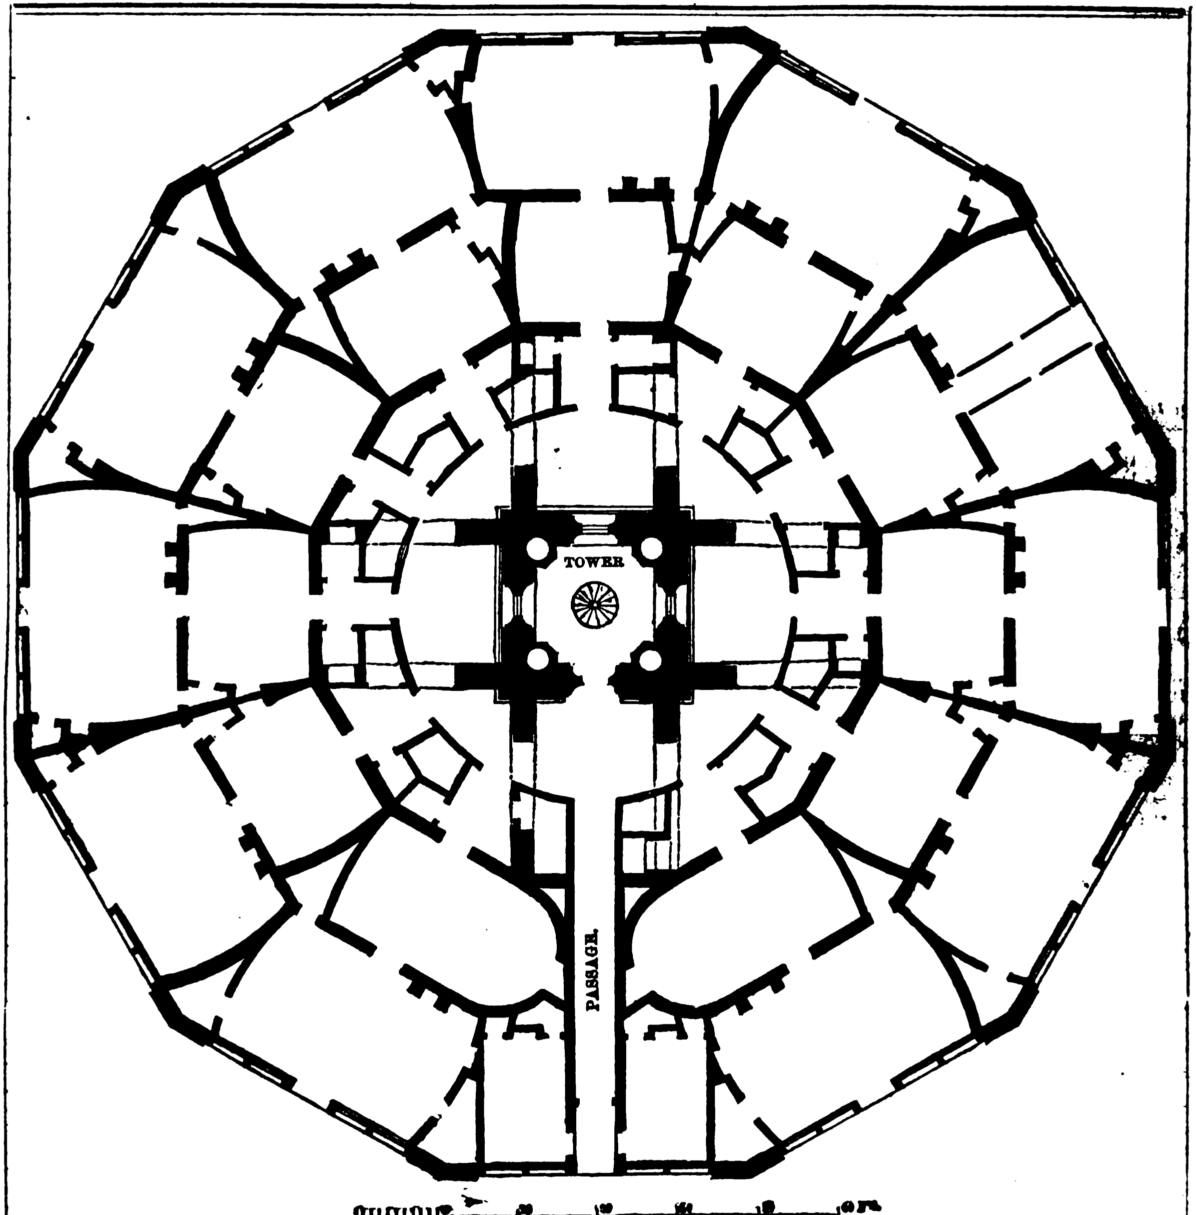
* Extract from the report of George W. Hemans, Esq., C.E., to His Grace the Duke of Leinster and the Right Hon. R. M. O'Ferrall, M.P.

† Ibid.



PLAN OF CLOCK TOWER AND OFFICES, CATTLE MARKET, LONDON.—Mr. Bunning, Architect.

(Referred to at A on Supplementary Illustration.)

THE METROPOLITAN CATTLE MARKET, LONDON.

We present two plans with this number—one showing the general arrangements of the entire market at Copenhagen Fields, and the other the design to an enlarged scale of the central building marked **A**, and comprehending bankers', clerks of market's, telegraph, and other offices, shops, &c., together with a lofty clock tower, which forms a prominent and architectural feature. The following descriptive particulars are from Mr. Hemans' recently-published report:—

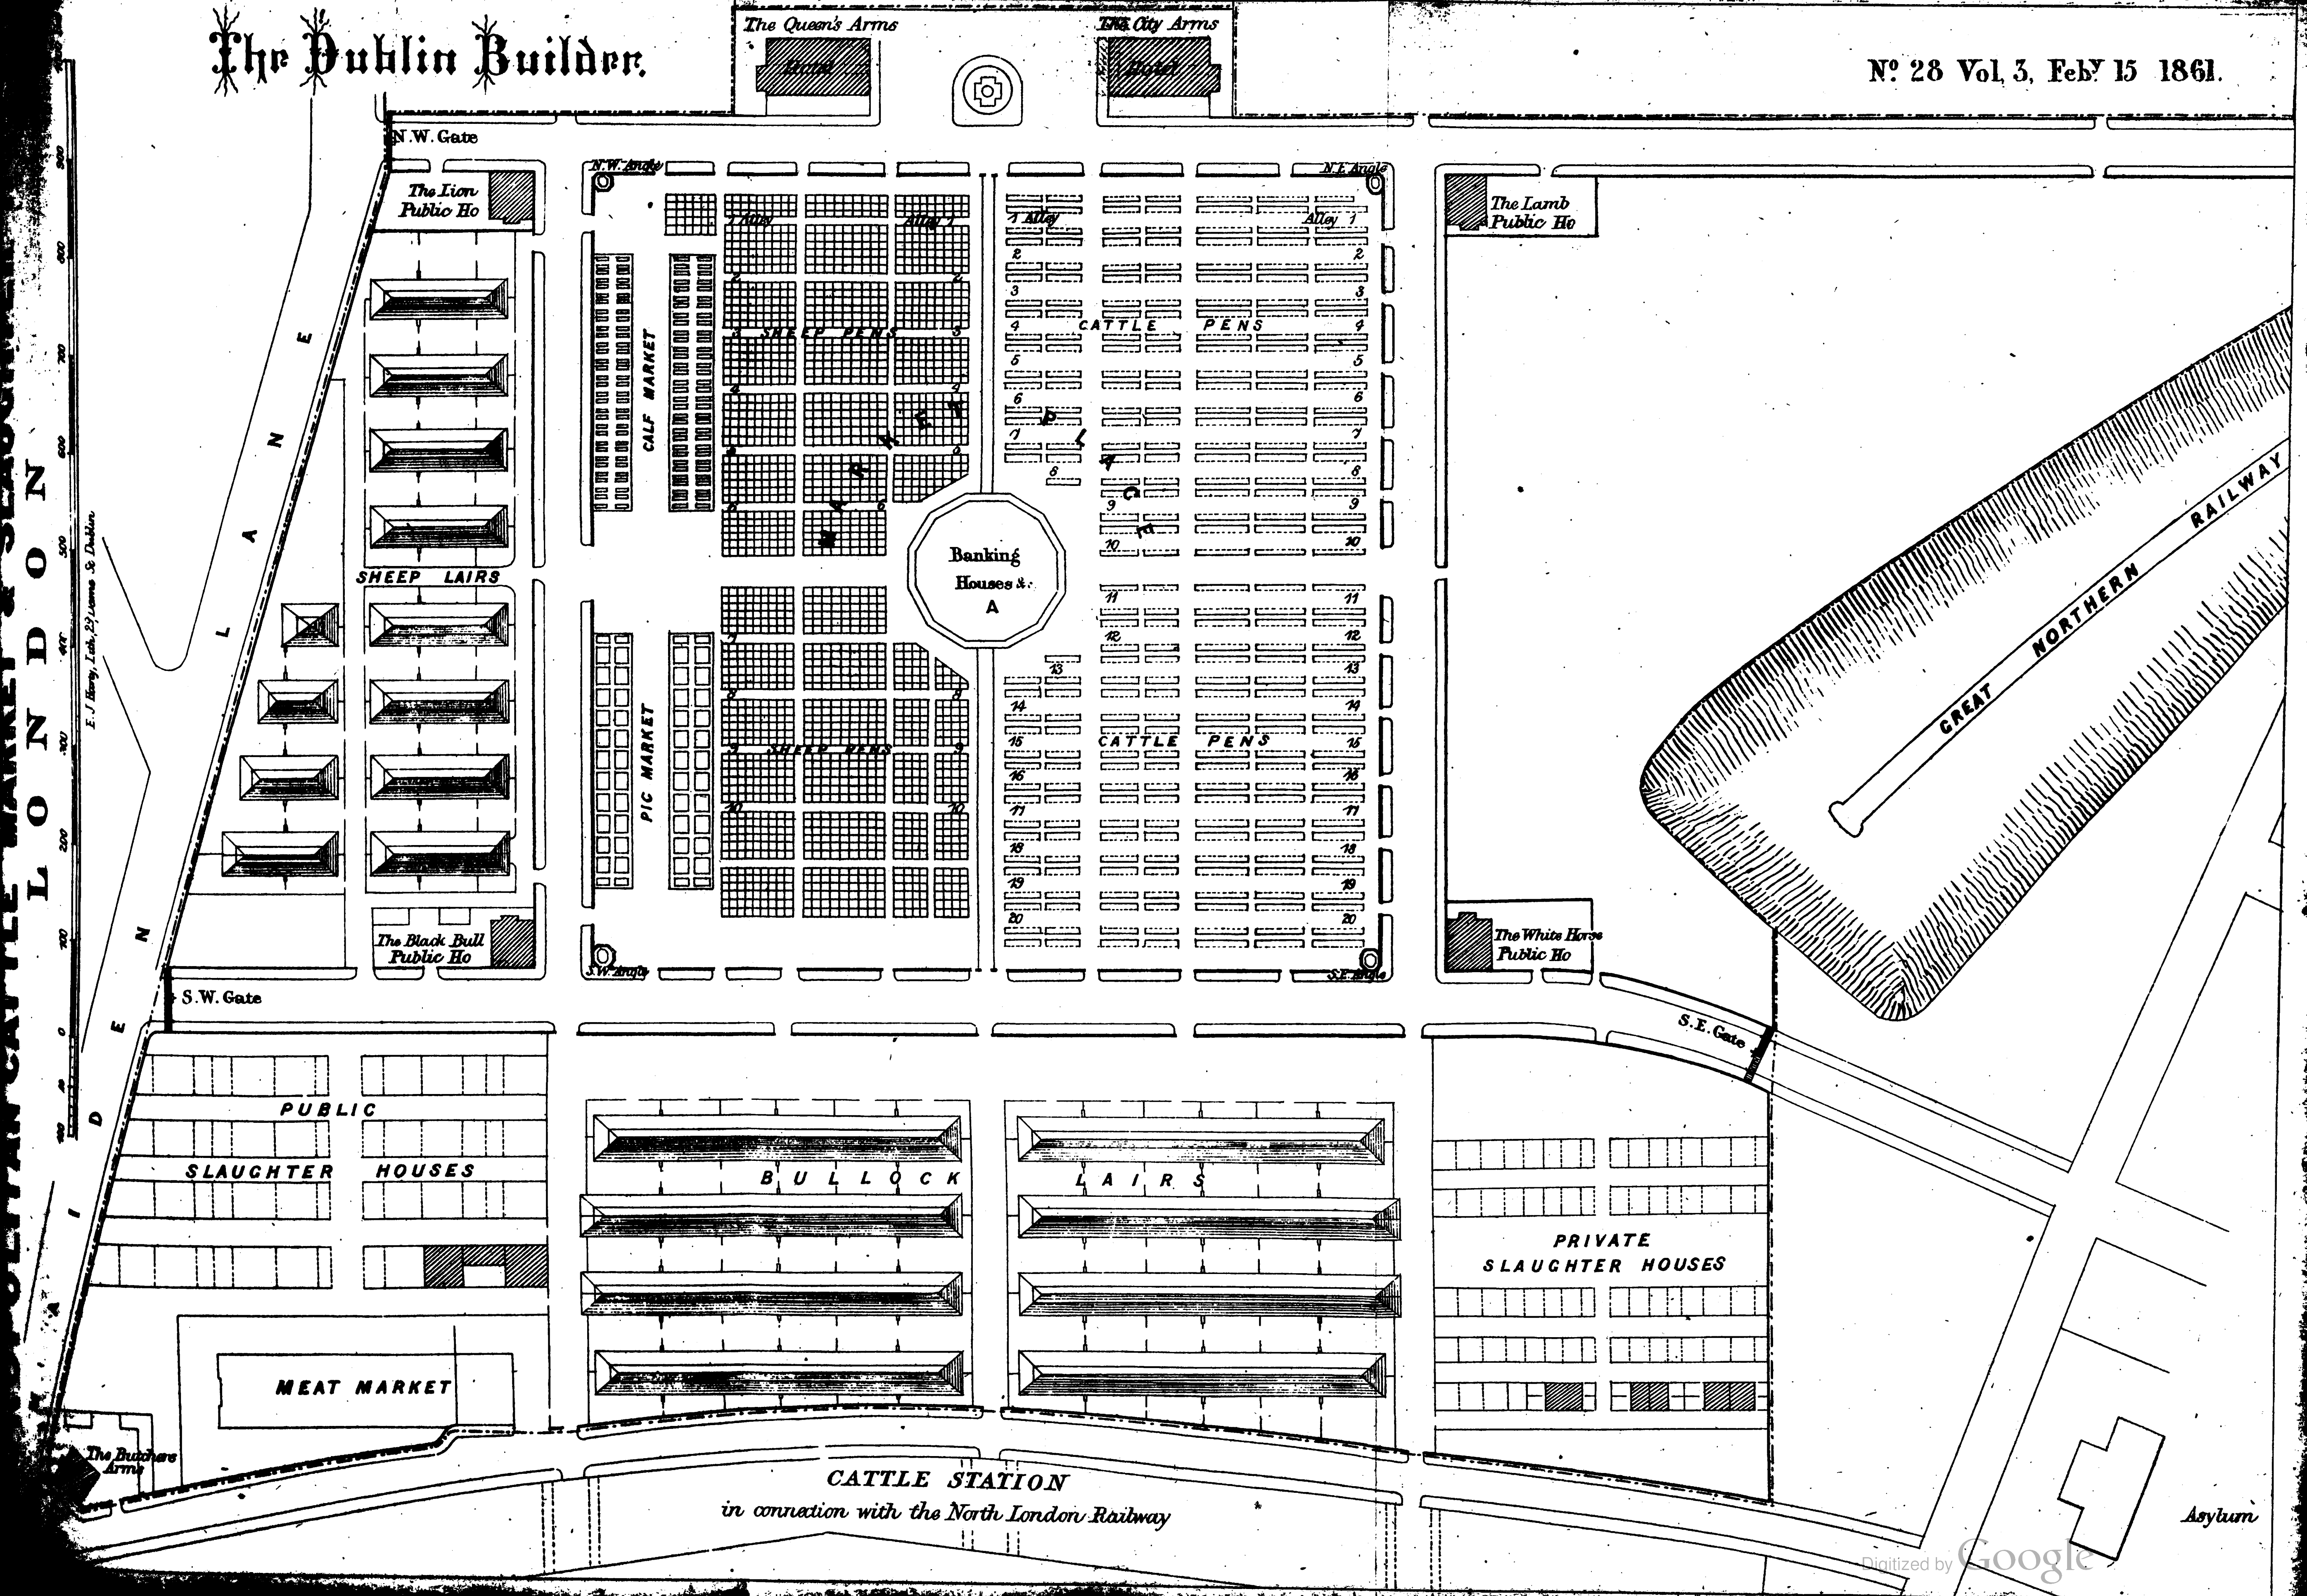
"The whole area of the land purchased by the Corporation of the city of London amounts to about 75¾ acres, of which about 7¼ acres, exclusive of roads, is devoted to an open uncovered space, divided and fitted up for the sale of horned cattle; about 4¼ acres are devoted to sheep pens, 1 acre to a pig market, and 1 acre to a calf market; making, in the whole, including passages and the space occupied by the bank buildings, an area of 15¼ acres (nearly) devoted to the public sale of cattle. In addition, nearly nine acres are devoted to bullock lairs, partly covered by sheds open at the sides, and 4½ acres to sheep lairs, also partly covered in the same manner. The building of slaughter-houses has been only carried out to a partial extent, and the probable area which will be covered by them cannot for the present be determined. Five large public-houses, two excellent hotels, banking houses, an expensive clock tower, and some other buildings have been erected in the most substantial manner. The whole area is enclosed by outer walls and inner iron railings of an expensive character, the lairs are paved with bricks, and the market-places with granite, and, in short, no expense has been spared to carry out the design in the most perfect manner. I am indebted to the kindness of Mr. Bunning, architect to the Corporation of the city of London, for the following details:—The cost of the land (75 acres 3 roods 15 perches) was £64,978 8s. 4d., the cost of the five public-houses and the two hotels about £79,000, and the outlay upon the roads, sewers, walling, iron railing, pens, paving lairs and a few slaughter-houses, amounts to £292,000; making, in the whole, an expenditure, up to this time of £436,000."

IMPROVEMENT OF LIMERICK HARBOUR.

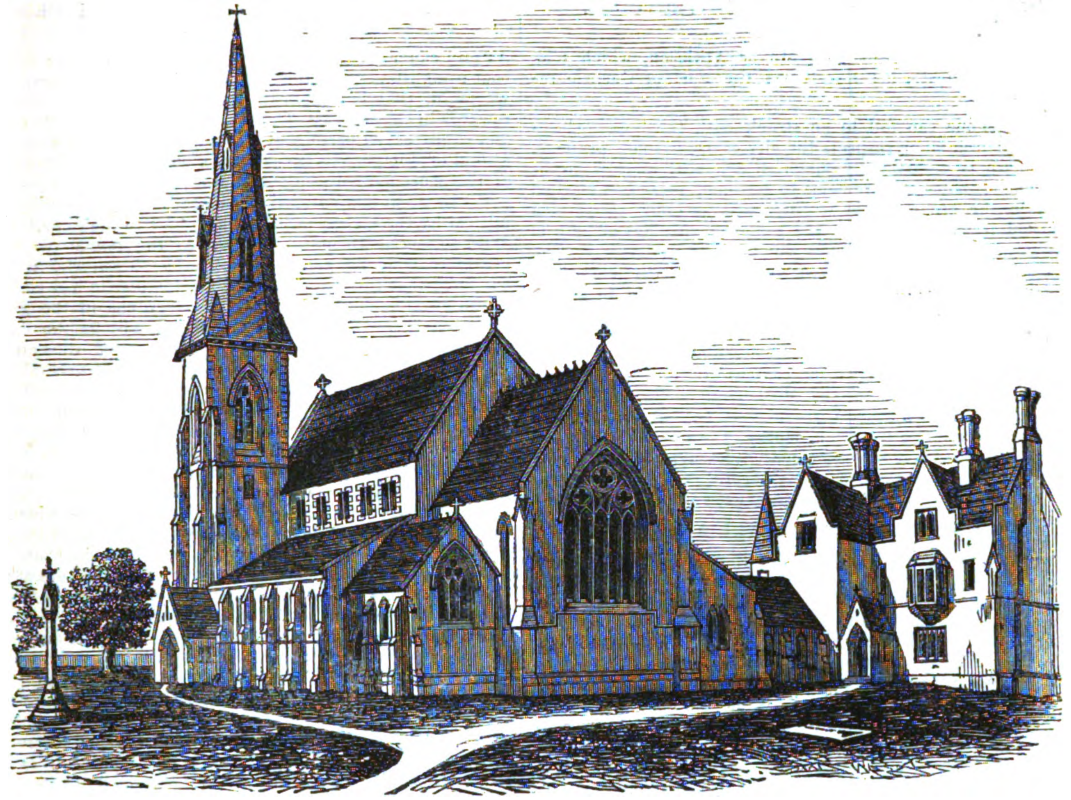
A proposed new arrangement with the Treasury will cause the transfer of the management of the harbour to the Board of Public Works, and after paying a stipulated sum annually to the former body, leave a surplus of about £4,500 to be expended on improving the dock and pier accommodation, for which much need exists.

The Dublin Builder.

No. 28 Vol. 3, Feby 15 1861.



THE LIBRARY
OF THE
[illegible]



CATHOLIC CHURCH, COVENTRY.

THE GOLDSMITH MEMORIAL.

FOR some time past the model of the intended statue to "poor Goldy"—Mr. Foley, R.A., sculptor—has been on view at Mr. Cranfield's gallery, Grafton-street, and, as might be supposed, numerous visitors availed themselves of the opportunity so afforded, and one and all unite in admiration of its excellence. The *pose* of the figure is natural, easy, and graceful, and the likeness—judging from the admitted portraits—replete with fidelity. In the left hand, which is elevated above the level of the breast, is an open book, from which the poet seems to be reading, and in the right, which is fully extended downwards, and at a slight distance from the person, a pencil is inserted between the fingers, suggesting a supposition of its being used in annotations. The garments are characteristic of the fashion of the period, and in all respects the artist seems to have carefully studied his subject. It will be doubtless highly creditable to him, as well as to our national spirit, and substantially perpetuate the memory of one of Ireland's brightest luminaries in the hemisphere of talent. The pedestal question seems yet to be decided on, and we trust that the committee will use wise discretion in selecting a design in every way suitable, so essential to the harmony and effect of the whole structure. To his Excellency the Earl of Carlisle be the immortal merit of originating the project now on the eve of maturity.

ART UNION OF IRELAND.

IT is proposed to adjust the minor prizes, so as to give one assured prize of at least one guinea intrinsic value to every five consecutive shares, independent of the chances in the general distribution. Thus each subscriber for each guinea subscribed would have one chance in the general distribution, besides one chance of the minor prize allotted to every five shares. The subscriber for five shares would be entitled at once to select one of the assured prizes, besides having his five chances in the general distribution. The Lord Chancellor considers the plan would operate favorably under certain restrictions. The secretary states that he has made calculations, and even on 1,000 shares a sum would remain from the principal prize fund fully equal to what had been so allocated heretofore, and with larger returns, the proportion of expenses would diminish so rapidly as to leave a very important proportion of the funds available for the principal prizes. Of course there would be no minor prizes except those assured as one in five, and even to them the same option of selection or adding to the amount might obtain as heretofore.

ÆSTHETICS, OR THE BEAUTIFUL IN THE FINE AND ORNAMENTAL ARTS.

A SERIES of lectures on this subject was commenced on the 13th instant, in the theatre of the Royal Dublin Society, by Mr. Henry M'Manus, R.H.A., Head Master over the Art Schools, the purport of which is to afford a simple and easy view of the object and end of the fine arts as a producer of the beautiful, showing, by illustration and description, the origin and progress of this quality in all ages and in all parts of the universe—marking its development under varied circumstances, until it became common property of man, to be with him as long as he is an intelligent and cultivated being; also, to make clear at once to the perception what would take years of reading and study to achieve, owing to the very imperfect state of art-literature, and its want of connection with the practical part of the arts, the absence of true criticism on art, and the very imperfectly understood position of the fine arts themselves. The first lecture was illustrated by a map, showing the locality of the several historic styles from their centre to where they overlap and merge into others, effecting the discovery of transition styles, a circumstance not clearly comprehensible till placed before the eyes in a practical shape. All the audience, which comprised the pupils of the schools and numerous visitors, were highly gratified and instructed by the lecturer's excellent demonstrations.

Notice has been given at the British Galleries of the National Gallery at South Kensington, that henceforth no copy is to be made of any picture, the painter of which is living, without his written consent.

Preparations are now in progress for establishing a new line of electric telegraph between Paris and London by Dieppe and Newhaven. Three wires from Paris will meet one from Havre at Malaunay, and the four will cross the Channel from Dieppe to Newhaven. When this line is completed, France will be connected with England by twelve wires—four from Calais to Dover, four from Boulogne to Folkestone, and four from Dieppe to Newhaven. These last are specially intended to connect Lyons, Bordeaux, and Marseilles direct with London.

The very interesting and historical church at Waltham Abbey, celebrated as the burial place of King Harold, the last of the Saxon kings, has lately undergone a thorough restoration, under the direction of Mr. W. Burgess, the architect of the memorial church at Constantinople.

VICEREGAL OPINION ON ARCHITECTURAL PROGRESS.

At the inaugural banquet of Lord Mayor Atkinson, which took place on the 7th inst., his Excellency the Earl of Carlisle remarked:—

"I think no one can fail to be struck with the improved appearance which in many respects the city of Dublin now presents. Though there is undoubtedly much which still remains to be wished, and I hope still remains to be done, there is a marked progress in the architectural improvement of your shops and houses, and it is gratifying to see that the members of both of the two great religious persuasions which divide our society seem intent upon improving the character and enhancing the dignity of ecclesiastical architecture. I would not be thought to lay an undue stress upon these outward demonstrations of piety, but I think still there is an incongruity in seeing the skill and genius of our artists lavished upon our private dwellings, and the various purposes of civil life, while we are content to leave in comparative neglect the temples of the Most High. Warned by the experience of the last year, I trust that no long period will elapse before this city procures a supply of water both plentiful and pure, and also takes sufficient guarantees against the recurrence of loss to property and life from fires."

AN ARCHITECTURAL ALLIANCE.

At a recent meeting of the Architectural Association of London the following resolution was adopted with reference to an architectural alliance:—"That having received a communication upon the question of an architectural alliance from the Northern Architectural Association, the committee consider it desirable that facilities should exist for communication with the various architectural bodies in the kingdom, to obtain their opinion, and, if need be, their co-operation, whenever such shall seem needful; and the committee are of opinion that each secretary of an architectural association should obtain the addresses of the other secretaries, and forward to them from time to time any information of importance that may come into their possession."

THE DICTIONARY OF ARCHITECTURE.

We desire to direct the special attention of our readers to an announcement appearing in our advertisement columns, from the Architectural Publication Society, and to the effect, that unless there be a speedy acquisition to the subscribers' ranks, so as to justify a reprint of some of the early numbers of the work, not a copy will be available after a very short time. This society—whose members have been unremitting in their labours, and which, by the way, are doubly meritorious, being gratuitous—demands much more consideration from the profession than a mere subscription for an equivalent, and although its course has been somewhat more slowly pursued than might have been desired, and resulting from limited resources, nevertheless it is *surely* approaching the goal of completion, and in a manner highly creditable to all concerned, and we may add nationally so. We trust that those who have not yet contributed their quota of support will do so *at once*, and save the society from the suggested alternative of destroying the plates of the numbers in question; furthermore, that when in the course of professional practice any matter of novelty or interest presents itself, it will be communicated to the honorary secretary of the department, to be recorded for the general weal.

BIOGRAPHICAL SKETCH OF INIGO JONES.

This celebrated architect was born in London about 1572. He was bred a joiner, but his skill in drawing recommended him to the notice of the Earl of Pembroke, who sent him to Italy, where he acquired a complete knowledge of architecture. James I. made him surveyor-general of his works, which office he discharged with great fidelity. He continued in the same post under Charles I., and had the superintendence of the building of St. Paul's, Covent Garden, with the management of the masques and interludes for the entertainment of the court. This brought him into a squabble with Ben Jonson, his coadjutor, who ridiculed him in his comedy of *Bartholomew Fair*, under the name of *Lantern Leatherhead.* He suffered considerably during the time of Cromwell, so that grief, misfortunes, and age, brought him to his grave in July, 1651. In 1655 appeared his *Discourse on Stonehenge*, in which he attempts to prove it to have been a Roman temple. As an architect, Inigo generally, but not always, shines to great advantage. He designed the palace of Whitehall and the Banquetting-house, the church and piazza of Covent Garden, Coleshill in Berkshire, Cobham-hall in Kent, and various other buildings, public and private. The principal of his designs were published in folio, in 1727, and some in 1744.

APPEAL FROM THE NATIONAL LIFEBOAT INSTITUTION.

After enumerating particulars connected with the several lifeboat establishments in the kingdom during the past year—whereby we learn, that independent of a sum of £908 8s. 4d. voted as rewards in that service, £203 4s. had also been granted for saving 245 shipwrecked persons by shore-boats and other means, making a total of 455 persons saved from a watery grave—the committee of this most philanthropic institution earnestly adds:—

"This great and national work has, however, only been accomplished by the society incurring liabilities to the extent of £5,419. With so sacred an object in view as the rescue of our fellow-creatures from an appalling death by shipwreck, it might be supposed that the National Lifeboat Institution had claims which would come home to the heart of every one in this great maritime country. Such it may be hoped will be the case as its operations become more generally known, and thus an abundant harvest, not only of popular sympathy, but of general pecuniary support, will be the permanent result. The committee of this institution do not, therefore, hesitate to solicit most earnestly the support of the community at large in aid of the benevolent objects of the National Lifeboat Institution. They cannot but sympathise with the vigorous efforts now being made by this society, to save the lives of shipwrecked crews. Their help was never more needed than at the present time, when, through the extraordinary exertions the society has made within the past few years, it has now one hundred and eight lifeboats under its management, for the maintenance of which, in a state of thorough efficiency, a large permanent *annual income* is absolutely needed, if its humane mission is to be perpetuated. We may add, that contributions in aid of the philanthropic and national objects of the Lifeboat Institution, are received by all the London and country bankers, and by its Secretary, 14, John-street, Adelphi, London."

An appeal which we have no doubt will meet with a hearty and general response, and the necessity for which is more impressively suggested by the recent melancholy events at Kingstown and along the Irish coast during the gale, to which localities increased resources would enable the institution to extend its operations more efficiently than at present. The following will show that even to the extent employed, the society has been instrumental in saving numerous lives during the period in question:—

The lifeboat stationed at Arklow, belonging to the above institution, was instrumental during a terrific gale from the N.E., and a fearful sea, in rescuing the crew of five men from a vessel which had got ashore between the south pier and the rocks. Owing to the very tempestuous state of the weather, it experienced immense difficulty in accomplishing her mission of mercy, but at last succeeded and brought the poor fellows safely ashore. The schooner *Margaret Ann* came ashore near Skerries, and her crew of five hands were taken off by the lifeboat of this institution. The crew of the smack *Gipsy* of Newry, were also taken off by the same valuable lifeboat in the height of the storm, at the back of the Skerries Islands. The lifeboat's crew behaved nobly on both occasions.

CONDITION OF THE AGRICULTURAL LABOURER.

There is no drawback affecting the condition of the labourer which calls so loudly for the sympathy of the rich and the benevolent, as that of providing something in the shape of habitable dwellings, by which the lives, morals, and comforts of the toiling masses could be preserved. What could be more deplorable than a peep into the miserable hovels into which so many of the hard-wrought sons of toil retire to rest after their daily labour ceases? The outline of these cabins present every shape of geometrical figure, from a square to a polygon, whilst the interior, as regards comfortable arrangements, is equally defective. How many instances could be enumerated, where the same habitation accommodates the goat and pig in company with the owner! Government loans may be easily obtained for building a byre, a piggery, or a stable, but the idea becomes quite impracticable when the appeal is made with a view of erecting a dwelling for the ploughman, the reaper, or the herdsman. Again, we find the farmsteadings for our cattle carefully and substantially built—every precaution being taken to secure the necessary requirements essential for the lives and comforts of the animals. The drainage is perfect, the houses are clean and plastered, the ventilation adequate, the workmanship excellent, and the apportionment noted out to suit the size and convenience of the animals intended to occupy the stalls. The poor man's house is built of the roughest and most inexpensive materials, and these are even stuck together regardless of permanency, neatness, or practical utility. The wind and rain find easy access through the crevices of the walls, along the door-posts, or through the roof; whilst the pools and dung-heaps in front evolve those deleterious gases sufficient to generate disease and mortality amongst the inmates who inhale them. Neither sufficient draining, proper ventilation, nor the requisite subdivision of the dwelling seem to be considered in the building of a house for the labourer, though the idea *predominates* when we contemplate erecting a dairy or a fowl-house.

The same system of mal-accommodation presents itself in the dwellings of the poor in our towns and cities, and the evil becomes magnified during the summer and autumn seasons, when migrating gangs of labourers go forth prepared for a harvest campaign. From the indiscriminate manner in which bodies of these are huddled together, it is not to be wondered at that disease and pestilence should be engendered, and that immorality, vice, and other evil propensities should be contracted.—*Correspondent of Agricultural Review.*

A writer in same journal, questioning the appreciation of the labouring class for the efforts made to ensure comfort and cleanliness, says—"We have heard, also, of some very curious perversities in this respect, exhibited in Ireland, perhaps not fifty miles from Dublin. A number of what were regarded by the builders as very nice cottages for labourers, were built of stone and mortar, slated overhead, and plastered inside. Near to these was a sort of deep, wide trench made, with a roof of rafters and thatch thrown over, and sort of partitions erected, so as to divide this covered trench into a row of cabins. To the astonishment of the enlightened builders, the labourers chose the stalls in the trenches, and allowed the superior cottages to remain tenantless."

Referring to the condition of the same class in Scotland, Mr. M'Laggan, at a recent meeting in Edinburgh, said—"The great majority of the cottages in Scotland consist but of one room, which answers the purpose of kitchen, bedroom, sitting, and entry room, and to it perhaps a small bed-closet is added; and this is all the accommodation for father and mother, and four or five of a family; a cottage of two rooms is an exception, and one of three rooms a very rare exception. And when we compare the comfortable accommodation for the beasts on the farm with the state of this one-roomed cottage, with its earthen floor broken into holes, and its unlathed walls, we may feel ashamed that in a system of agriculture considered second to none in the world, and indebted for its superiority to an enlightened proprietary, and an intelligent and enterprising tenantry, the labourers who bear such an important part in it should be worse housed than the beasts on the farm. I have visited some such cottages when sickness had entered them; I have seen the beds occupied by three or four children with the flushed face of fever—on the one side the shrouded remains of the mother who nursed them, on the other the grief-stricken father, with all his joys buried in that coffin, and unnerved at the thoughts of the dismal future before him."

ESTIMATING DISCREPANCIES.

As an illustration of one of those numerous problems suggested in the course of building practice, which not alone completely puzzles the public, but the wiseacres of the honourable fraternity themselves, we beg to draw attention to the following, and to express a conviction that to whatever extent editors and correspondents of journals may exert themselves in unravelling the mysterious web, the discrepancies in builders' estimates will ever be a "*pons asinorum*," not to be solved by the most accomplished of our modern mathematicians:—

For the erection of a new convent and schools at Kenmare (as advertised in the DUBLIN BUILDER)—

Mr. Stokes, county surveyor, Tralee	£9,000 !!!
Mr. O'Callaghan, Killarney	4,200
Mr. M'Donnell, Kanturk	3,950
Mr. Murphy, Bantry (accepted)	3,853 !!!

For the erection of model cottages, at Blarney Road, Cork, for the Cork Association for improving the dwellings of the labouring classes; Mr. Richard R. Brash, architect:—

Thomas Walsh	£1,180
Murray and Meade	980
Edward Murphy	845
Martin Clayton	775
Simon Kenefick (accepted)	730
James O'Donnell	699

[NOTE—We shall esteem it as a favour by lists of tenders being sent to us for publication.]

OBITUARY.

February 1st, at his residence, 24, Queen's-square, Mr. Peter Martin, builder, aged 72 years.

We have heard of the death of Mr. George Gregory. C.E., son of Mr. John Gregory, C.E., formerly of this city, which took place, suddenly, in the State of Wisconsin, America, recently.

CONTINUED DECAY IN THE STONEWORK OF THE PALACE AT WESTMINSTER.

It seems that all the preservative processes applied to the stonework of this structure have up to the present proved unavailing, and it is still reported "to be rotting away and presenting a honeycombed appearance." Viewing it a few months since, it did not appear quite so bad as that, but it is sufficiently so to leave no doubt of its total decay being a mere question of *time.* Messrs. Ransome and Szerelmey, therefore, may rest—at least as regards this building—in their argument for priority of their respective processes; and we apprehend that all other remedies, but a total refacing with a better quality of stone, will prove quite useless. The First Commissioner of Works has decided on no further action in the matter until a committee of the first architects, engineers, and chemists shall have reported on the matter. What if the doctors should differ? Mr. Tite suggests the cause of the decay to have been the cutting of the stone from a quarry whose geological construction was only half developed.

Correspondence.

BRICK DRESSINGS—NEW PRESBYTERIAN CHURCH AT SYDENHAM, NEAR BELFAST.

TO THE EDITOR OF THE DUBLIN BUILDER.

SIR—In the last number of the DUBLIN BUILDER you give a description of the above-mentioned building, copied from a local journal, in which it is correctly stated that "the entire of the building, the tracery of the windows excepted, will be executed in brick, with dressings, *weatherings*, &c., of the same material." Happening to pay a passing visit to this building lately, it struck me forcibly that in it, as well as many other of our modern erections, the introduction of brick dressings is being carried much too far. In this case the "weatherings" have proved lamentably unfit to serve as such. Being composed of brick, and consequently requiring to be jointed with mortar, the latter material has so far given way under the combined action of rain and frost, that the brickwork has completely lost its "bond," and the consequence is, that the bricks forming the weatherings of the buttresses could be easily lifted off by the hand, and even many of the bricks themselves have either thrown off one or more of their corners, or a considerable portion of their surface, from the same cause. There is also a projecting string course of brick, of which much the same might be said. Would it not be well for those who admire "brick dressings" to confine their application to the *vertical* portions of the buildings in which they are adopted, and to form the "weatherings" and all such like projections, if not of stone, at least of some material that will not require too many joints looking weatherward?—Yours, &c., TYRO.

Belfast, 11th February, 1861.

Alderman George Roe addressed another letter recently to the *Freeman's Journal* about the College wall, the street disfigurements and encroachments going forward (so frequently pointed out in the DUBLIN BUILDER), and the desirability of another bridge over the Liffey opposite Lower Gardiner-street.

The standing orders have been declared complied with in the case of the following new undertakings:—Rathkeale and Newcastle junction, at a cost of £50,000. Enniskillen and Bundoran Railway. Cork, Blarney, and Macroom Railway.—For a line from Cork by Blarney to Macroom and branch to the Great Southern and Western, at a cost of £140,000. Great Northern and Western (of Ireland) Railway.—For extension at a cost of £85,000.

The bill introduced by the Cork and Youghal Railway Company for the purpose of extending the line to the quay at Youghal, and to enable arrangements to be made with the Cork Harbour Commissioners, has passed the standing orders. The cost of the extension is estimated at £35,000.

An unusually large number of bills relating to public undertakings in Ireland will occupy the attention of committees of the house in the present session. Indeed, since the memorable year of the railway mania, there has not been so good a prospect for the parliamentary bar. The contest between the Dublin and Meath Railway Company and the Midland Company for an independent station in Dublin will be resumed, and the agents of both parties speak confidently of success.

We regret to perceive that a destructive fire broke out lately at the establishment of Mr. Stanley, 3, Great Turnstile, Holborn, mathematical instrument and T square manufacturer. This is a very narrow thoroughfare, leading to New Square, Lincoln's Inn, and consequently presented great obstacles towards a speedy extinction. Much property was consumed, but not such as to affect the usual transaction of business.

Notes of New Works.

Extensive additions are being made to Grand Canal-street schools; Mr. Joseph Maguire, architect, Mr. Bolton, builder. Expenditure about £1,700.

An immediate extension of the railway terminus at Westland-row has been determined on, and plans prepared by the company's architect, Mr. George Wilkinson. The three houses respectively occupied by Mr. O'Gorman, auctioneer (corner of Great Brunswick-street), Chester and Holyhead or London and North-Western Railway Company, and Maguire the confectioner will be included. The front of the building will face Great Brunswick-street instead of Westland-row, as at present, and will be of an architectural character. The position is admirably adapted for a building which shall form an acquisition to our street architecture, and we doubt not that the proverbial enterprise of the company will ensure the desideratum.

A new National Bank house with officers' apartments to be erected at Ennis. Mr. Caldbeck, architect. Tenders are invited.

A clock tower is about to be erected in the town of Letterkenny. The site will be in the market square.

Additions and alterations are about to be made to Killadeas House, the seat of Captain Irvine, Co. Fermanagh; also a new parsonage house is to be erected close by.

The County Grand Jury of Cavan are desirous of receiving estimates and specifications for heating the Record Court.

Additions and alterations are to be made to Cormeen House, Ballybay, for J. Thompson Tennent, Esq., J.P.; Mr. Raffles Brown, architect.

The new police station at Ballybrack has been completed.

Extensive improvements are being made to Ormond Castle, Kilkenny, under the direction of Messrs. Deane and Woodward, architects. Messrs. Ross and Murray are executing some important hydraulic and plumbing works in connection therewith.

The above-named architects have submitted a design for the Great Exhibition building of 1862.

The neighbourhood of Ballybrack, on the Bray and Kingstown branch of the Dublin and Wicklow line, is the scene of much building improvements. A large mansion is being commenced under the directions of Messrs. Lanyon, Lynn, and Lanyon, architects, for the Hon. Judge Dobbs, and will cost some £4,000 or £5,000. Messrs. Deane and Woodward have also designed six new dwelling houses for different parties, amongst whom is Mr. Joseph Robinson, the eminent concert singer. The foundations have been laid out. The two houses in course of construction for Mr. Boyle will soon be completed. A villa is erecting in same locality for J. H. Curry, Esq., local manager of the Royal Insurance Company, under the directions of Mr. Joseph Maguire, architect, Mr. Brophy, builder, and will cost about £1,400.

Two dwelling-houses—semi-detached—have been completed at Vico-road, Dalkey, for Mr. Henry Gonne, after drawings by Mr. Lyons, architect, and present gabled cantilever roofs, with ornamental brackets, large bay windows, commanding magnificent views of the surrounding unsurpassedly beautiful scenery, and fitted throughout with storm shutters, essential during the winter months in this exposed situation. Internally the arrangements are peculiarly commodious and suitable, and externally they are finished in compo, lined in ashlar courses. Another, of somewhat similar character, is being commenced; same architect. The obstruction offered to the continuance of this road to Killiney, by *a wall built right across it*, is a serious drawback to the improvement of the neighbourhood; but we are quite sure that the characteristic amiability and consideration of the worthy lord of the manor of Killiney, and the no doubt *unwilling* perpetrator of this obstruction, Mr. Warren, will induce him "to take the bright view of the question," forgetful of all else, and accord to the public a very decided boon. A notice has been posted on the wall in question, stating that all efforts had hitherto failed to induce consent, but we are far from believing that that gentleman is incapable of yielding to persuasion, and feel convinced that the memorialists will *yet* have occasion to say, with Richelieu, "*never say fail again.*"

A new mansion house is in course of erection at Bray for Thomas Lefroy, Esq., Q.C., under the directions of Messrs. Lanyon, Lynn, and Lanyon, architects; Mr. Lee, builder. Messrs. Hogan and Son have contracted separately for all the plastering works. Expenditure about £2,000.

The National Gallery, or Dargan Institution, so frequently noticed in these columns, is now in progress of roofing, portions of the slating being completed. It is to be hoped that a proportionate delay will not arise from the present stage of the works to the final completion as that which has hitherto prevailed.

MONUMENTAL.

The Government have commissioned Mr. John Noble, sculptor, to execute the statue of the late Sir John Franklin, intended for Trafalgar-square, London. It will cost £2,000.

A competition is about to take place between Messrs. Keed, Noble, Bell, and Munro, sculptors, for the monument to Hallam in St. Paul's Cathedral.

Various opinions have been expressed upon the character the intended memorial to the late Sir Henry Marsh, Bart., should assume, some desiring that an hospital should be erected and endowed; others, that suitable statues be placed either in the College of Physicians or in some of the public squares or thoroughfares.

We have seen at Mr. Kirk's studio, Jervis-street, a model of the intended Crampton memorial, but are not in a position to give a perfect description of it as yet.

A memorial is about to be erected (we presume at Glasnevin Cemetery), by subscription, to the late Rev. James Fay, C.C.

NOTES IN THE COURTS.

M'Donnell v. *Benson.*—Action for £46 for work done as an assistant civil engineer and surveyor to Sir John Benson, on the proposed Limerick and Cork line. Defendant lodged £6 in Court, but did not appear. Verdict, £59 over and above that amount.

A. J. Bergin v. *John Star.*—Action for £81 alleged to be due under a builder's contract for work at Adam and Eve chapel. Defendant lodged £28 in Court, the amount stated to have been agreed on for same. Plaintiff claimed £53 in addition for authorised extras, and maintained that an agreement was entered into between him and defendant, that the latter should contract for the work, and the plaintiff to be sub-contractor. Verdict, £40 over and above the sum lodged in Court.

Heffernan v. *the Crookhaven Mining Company.*—Action for the sum of £190 for work and labour alleged to have been done for the defendants in mining shares taken, making maps, issuing prospectuses, &c. The plaintiff was a civil engineer, and was engaged by Mr. Hemming, the secretary of the company, to perform the services specified. The defendants did not deny that services had been rendered, and had lodged £80 in Court as the sum to which they considered the plaintiff entitled.

Forster v. *Worrall.*—Plaintiffs are lithographers, and sought to recover from the defendant, Mr. J. Worrall, county surveyor of Tipperary, a sum of £128 1s. 8d. for work done and materials provided. The defendant pleaded that having been engaged to make surveys of estates sold in the Incumbered Estates Court, employed the plaintiffs to lithograph and colour maps; that it was agreed to pay them 50 per cent. of the amount as taxed by the officers of the court; that the defendant received £71 12s.; that the plaintiffs were entitled to £35 16s., the half of this amount; that defendant paid plaintiff £30 in part payment since the action was commenced, which plaintiff accepted; and that £19 0s. 6d. remain due, which defendant lodged in court. Verdict for plaintiff for £47 2s. 2d. over the sum lodged in court.

Cosgrave v. *Ellis.*—Action for work and labour, and recovery of damages for breach of contract. Plaintiff is a clerk of works, and defendant a builder. Plaintiff was employed by defendant, he alleged, on the following terms:—To make out plans and specifications of works for which defendant intended to contract, without charge in the first instance; but in case defendant became contractor, plaintiff was to be his superintendent, at a weekly salary of £1 12s. 6d. as long as the works continued. Plaintiff made out the plans and specifications, for which he claimed a sum of £25 1s. 10d.; he was engaged for sixteen weeks as clerk of works over the building of sixteen houses in Rathmines, for which defendant had contracted, and for which he charged £26, at the rate of £1 12s. 6d. per week; the whole of the houses would have occupied, upon the calculation that four of them had been completed in sixteen weeks, forty-eight weeks in the building after he had been dismissed from the defendant's employment, and for these forty-eight weeks he claimed £78; he also claimed damages for wrongful dismissal. Defendant denied the contract, and pleaded that by way of confession and avoidance, that it had been waived or rescinded by the plaintiff, prior to the alleged breach that the plaintiff had so misconducted himself in his employment, that he was obliged to dismiss him, and that he had paid him a sum of £37 17s. 6d. which was sufficient compensation for any work performed for him. The jury found for plaintiff, damages £24 11s.

Sweeny v. *Lemon.*—Action brought by plaintiff against defendant to recover damages for alleged trespass. An arrangement was come to, by defendant paying £50 and costs—the plaintiff executing a release.

We are gratified to notice that a couple of impending actions—previously alluded to—have been arranged to mutual satisfaction.

COURT OF BANKRUPTCY AND INSOLVENCY.

In re John Lennon.—The insolvent—a builder—was opposed by Mr. Joseph Kelly, timber merchant, on the ground that he contracted the debt by representing that he was to give an order on Captain Bailey, for whom he was performing a building contract, for the amount of goods supplied, and on the further ground that he put in a sham plea to an action brought against him for the recovery of the debt due. Mr. Robinson, a gentleman in the employment of Mr. Kelly, testified that goods were supplied for the purposes of the contract with Mr. Bailey to the amount of above £100, and Mr. Bailey offered to pay Mr. Kelly £50 of his debt, if the insolvent gave an order on him to that amount, but he would not do so. Another witness stated that the last portion of the goods was delivered on the express condition that Mr. Bailey would pay for them when he came home from the continent. Mr. Greaves, for the insolvent, denied that this was a true statement of the case, and said it would be contradicted by the architect of Mr. Bailey. Judge Berwick said that the insolvent appeared to have entered into an imprudent contract, and was unable to pay Mr. Kelly. He would adjourn the case until the architect was brought up, but in the meantime he would advise the insolvent or his friend to pay Mr. Kelly the costs he was put to by the filing of the alleged sham plea. Adjourned for a fortnight.

In re Hugh Kelly, a builder, saw mill proprietor, and importer of building materials, Sir John's Quay, in this city.—The bankrupt offered 8s. 6d. in the pound—2s. 6d. to be paid at once, and the balance by instalments, within a limited period, but the majority of the creditors refused to accept the composition. The appointment of a trade assignee will not take place for a fortnight.

THE ATTRIBUTES OF ANGELO.

Saints bent o'er him, sigh'd and wept,
  Angels hover'd to and fro,
Genius still her vigils kept
  By the couch of Angelo.

Ardent faith and holy love,
  Energy with youthful glow,
Inspiration from above—
  All were join'd in Angelo.

Painter, sculptor, architect,
  Unsurpassed in the trio;
Art encircling intellect,
  Time's immortal Angelo!

'Neath Saint Peter's glorious dome,
  In forum, fane, or studio,
What e'er he did—thy greatness, Rome!
  Was typified in Angelo.

In youth or age, around that brow
  Fame twined her golden wreath in blow;
And years alone could never bow
  The form erect of Angelo.

Most honor'd still through all extent,
  By Tiber, Thames, or Liffey's flow,
Thy name alone—a monument—
  Wondrous, gifted Angelo!

C. C. H——Y.

GAS LIGHTING AT STUART HALL.—The Right Hon. the Earl of Castlestuart having determined to light his residence by means of the patent apparatus of Messrs. Edmundson, of this city, that firm has been instructed to light up Stuart Hall, Stewartstown, county Tyrone, with gas works. A similar apparatus was recently erected by Messrs. Edmundson at Rossmore Park, in the adjoining county of Monaghan, for Lord Rossmore.

A project is on foot in London for uniting Piccadilly with the Strand by a gently curved street, commencing at the head of Coventry-street and continuing to Chandos and King William streets. This would necessitate comparatively little pulling down, and would open up a most suitable opportunity for extending the National Gallery, and having a handsome front for same building towards the proposed street.

The fifth evening scientific meeting of the Royal Dublin Society will take place on Monday evening, the 18th inst. Professor Davy will read a paper on the injurious effects of the employment of arsenical pigments; Dr. Danglish on the manufacture and peculiarities of ærated bread; Mr. Henry Shaw on a new patent railway break; Mr. Henry Hennessy on anonymous publications; and Mr. T. W. Connor on competitive examinations.

Reviews.

Examples of London and Provincial Street Architecture in the Victorian Age. London: F. Tallis.

JUDGING from the copies of the plates that have reached us, this work promises to be one of merit, with the suggestive and practical combined. Plate 1 displays a perspective elevation of the Promoter Life Assurance Company's offices in Fleet-street, with which we are quite familiar, but must remark, that the style of illustration is somewhat too pictorial, and a more subdued tone of colouring would be more suitable. Plate 3, representing premises in Birmingham, is decidedly better as to manipulation, and the details are a desirable addenda. From the great variety of subjects to be embraced by this work—presenting examples worthy of imitation in street architecture—we have no hesitation in pronouncing it to be one which, if carried on judiciously and spiritedly, will surely command an extensive patronage.

The Golden Quiver, or Poems for Children. By S. G. Stevenson. London: Darton & Co, 58, Holborn Hill.

First impressions are, said to be, the most lasting, it is therefore a reasonable assumption that educational training should commence in the cradle, and that *ab initio* it should be unexceptionally excellent. The majority of nursery rhymes published now a days are rather more calculated to distort the tender intellect of a child, than to furnish it desirably; all description of fabulous, vapid, and exaggerated nonsense, in ill-measured rhymes, being popular amongst all classes from the highest to the lowest, unquestionably leaving certain dregs behind that no subsequent cultivation will fully eradicate. We can pronounce this little work free from restriction, the poems being calculated both to gratify the youthful mind and cultivate a taste for the muse; the subjects, moreover, are most happily selected.

Strike among Workmen. Dublin: M'Glashan and Gill.

A PAMPHLET under this title, embodying a series of six letters addressed to Lord Brougham—but which the writer complains *were never taken any notice of* by his lordship—has been published by Mr. Thomas M'Anaspie, "for more than thirty years practical artist and *tradesman manufacturer*, &c., in both plain and ornamental departments in a branch of the building trade." The object of the pamphlet is to endeavour to illustrate the causes and consequences of strikes; the effects of the present and past state of the building trade on general taxation; the means for raising from *two* items *eighty-five millions sterling* per annum in favour of the Exchequer; take *all taxation off food*; rear, without *one farthing of outlay* to the State, an army of *two millions of well-disciplined men*; prevent *civil commotion between capital and labour*; secure for every tradesman of servitude, skill, and ability, the contracts, control and benefits of his separate trade; prevent jobbing; secure work 25 per cent. cheaper and 50 per cent. better, &c., &c. We can only excuse the alleged impoliteness on the part of his lordship—who in letter No. I. is designated a "public benefactor" and "man of great mind," and in letter No. VI. as "an English statesman without sympathy"—by assuming that his lordship, after an attentive perusal, became convinced that the scheme was far too comprehensive for an *ordinary* intellect, and was, therefore, content to leave the merit of its development *exclusively* to his correspondent, who has certainly displayed an unlimited amount of courage in grappling with *so many* items connected with political economy, each one of which forms a separate subject in itself quite sufficient to occupy at one time the attention of any of our modern legislators. We have no doubt that many tradesmen, equally enthusiastic as the author, will read the pamphlet with very great pleasure. The financial calculations are confessedly quite beyond *our* capacity, but we are assured that the author has framed them on most reliable data, carefully studied.

The Dublin Waterworks Bill has been read a second time before the House of Commons, and submitted to a select committee.

Miscellaneous.

GEOLOGICAL SOCIETY.—An election of officers has taken place with the following result:—Rev. Professor Haughton, *President*; Robert Callwell, R. Malley, James Apjohn, Professor W. H. Harvey and the Rev. H. Lloyd, *Vice-President*. Gilbert Sanders, and P. J. Sidney, *Treasurers*. Joseph B. Jukes, and R. H. Scott, *Secretaries*. Council—Lord Talbot de Malahide, Sir R. Griffiths, Bart., John Kelly, Samuel Dowling, J. B. Doyle, J. R. Kinahan, M.D.; Alexander Carte, M.B.; Edward Wright, LL.D.; S. Gordon, M.D.; W. H. Bailey, Alexander Gages, R. S. Reeves, G. M'Dowell, Rev. J. A. Galbraith, and W. Andrews. Sir Leopold M'Clintock was unanimously elected an honorary member.

IRISH ARCHÆOLOGICAL AND CELTIC SOCIETY.—The sheets of the following important works, now in progress of printing by the society, were submitted at a recent meeting:—1. The Book of Ancient Irish Hymns, edited by Dr. Todd, from a very ancient manuscript in the library of Trinity College, Dublin, printed to the commencement of Fiech's Hymn on St. Patrick. 2. The Irish Topographical Poems of O'Dubhagain and O'Huidhrin, printed to page 150, under the editorship of Dr. John O'Donovan, enumerating the various native families and their territories early in the 14th century, illustrated with copious notes and a dissertation by the editor on Irish surnames, their mutations, and Anglicised forms. 3. The Donegal Martyrology or Calendar of Native Irish Saints, and the localities with which they were connected, numbers of which still retain their names strangely altered and corrupted by time. This work, with large historical and topographical illustrations, is being printed by the society from the original text by the O'Clerighs, popularly known as the "Four Masters," now preserved in the library of the Duke of Burgundy at Brussels.

MECHANICS' INSTITUTE.—The following parties constitute the board of direction of this institute for the present year:—*Treasurer*, James Haughton, Esq.; *Auditors*, Messrs. Digges, P. Kelleher, and John Sullivan; *Committee*, (operatives) Messrs. Hugh M'Neill, James Pollard, A. Flannery, E. C. Ferris, Thomas Dobbin, John Gaynor, Edward Hart, John O'Driscoll, Joseph Owens, G. O'Connor, T. A. Bowen; (non-operatives) Michael Molloy, John Christopher Magan Campion; John Elwood, Cornelius M'Swiney, J. P. Moore, L. J. Walsh, and J. Kenny.

THE CONNOREE MINING COMPANY.—A half-yearly meeting took place on the 6th inst., Dr. Waller in the chair. Amongst other matters the report stated that "the great difficulty of procuring a sufficient and permanent supply of miners and labourers has been a subject of anxious consideration with the directors, and that they had come to the conviction that this difficulty could be removed only by building dwelling-houses for workmen and their families, and thus making it their interest to attach themselves permanently to the mines. With a view to this object the directors have under their consideration an arrangement for obtaining sufficient land suitably situated; and they have no doubt, when carried out, that a moderate rent upon the houses will yield interest upon the sums that shall be expended on their erection. The secretary read a lengthened report from the managing director, respecting several valuable discoveries of metalliferous deposit on the northern portion of land whereon the company's mining operations are being carried on, and giving a statement of the progress and present condition of the works in the respective shafts and adits, and described the character of the lode recently discovered as being peculiarly rich; also of the effective condition of the machinery, including the new pumping steam-engine, the machinery for dressing the ores, &c."

THE KINGSTOWN COMMISSIONERS AND THE DUBLIN WATER WORKS BILL.—There seems to be a desire on the part of this body to follow the example of the Rathmines Commissioners, and offer obstacles to the passing of the proposed bill for the better supply of Dublin. A petition with that object in view is being prepared.

THE BALDOYLE ESTATES.—The City of Dublin Corporation possesses extensive estates in this locality, and a reduction of rents has been sought for by Colonel White and Captain Darley, tenants, and recommended by a committee; but subsequently the opinions of Sergeant (now Solicitor-General) Lawson and Attorney-General (now Baron) Deasy were sought, and they were against the legality of the reduction. The question has been a subject for much discussion at a recent meeting.

PROGRESS OF DERRY.—Referring to the rapidly improving condition of this town and neighbourhood a local correspondent says:—"Derry is now taking the position Belfast did twenty years since; a large quantity of building is going on, and as much or more in prospective. Wages are advancing, and there is a complete run on materials."

NEW BRIDGE OVER THE THAMES.—It is proposed to construct a new bridge over the Thames from Kew to Brentford, and to make a road in connection with it in the parishes of Isleworth and Ealing. The Great Western Railway and Brentford Railway are to subscribe to the undertaking. It is to be a toll bridge.

INTERNATIONAL EXHIBITION OF 1862.—It is stated on authority that if an International Exhibition of Works of Art and Industry had not been announced to take place in London in 1862, it was the intention of the Emperor of the French that one should be held in Paris, but that now the French will give way to the British exhibition.

A GRACEFUL TRIBUTE TO MR. FAIRBAIRN.—A royal medal has been awarded to Mr. William Fairbairn, F.R.S., for his various experimental inquiries on the properties of the materials employed in mechanical construction, contained in the "Philosophical Transactions," and the publications of other scientific societies. The following is an extract from the address of Major-General Sabine, who, as chairman of the meeting, presented the address:—"Mr. Fairbairn's first scientific publication was, I believe, a small volume published in 1831, on 'Canal Navigation,' illustrative of the advantage of the use of steam as a moving power on canals. In this work he detailed the results of experiments made on the Forth and Clyde Canal, and on other canals in Scotland, and recorded experiments made about the same time by other parties as to the traction of light boats by horse power at high velocities. In 1837 he contributed his first paper to the Manchester Literary and Philosophical Society, being 'An Experimental Inquiry into the Strength and other properties of Cast Iron.' This was the first of many valuable papers on the same and similar subjects which have been from time to time published in the 'Memoirs of the Manchester Society,' in those of the British Association and the Institution of Civil Engineers, and in the 'Philosophical Transactions.' It is well known also, and has been warmly acknowledged by Mr. Eaton Hodgkinson, that Mr. Fairbairn rendered most valuable assistance to Mr. Hodgkinson in his experimental inquiries into the strength of iron, for which the Royal medal was awarded in 1841, by placing at Mr. Hodgkinson's disposal his works at Manchester, in which the experiments were conducted free of cost. In the transactions of the Manchester Geological Society, in 1841, there is a paper by Mr. Fairbairn on the economy of raising water from coal mines; and in Weale's Quarterly Papers on Engineering an account of his ventilating water wheel, a very material improvement in the construction of water wheels. Since that time his experimental researches and his contributions to various scientific bodies have been very numerous and important. Amongst these I may specify papers on fire-proof constructions; on the strength of iron, and the best forms of beams and pillars; on boiler explosions; on the collapse of tubes under pressure; on the density of steam; on the principle of construction of iron ships; and other kindred subjects—many of these being within the period required by the terms of the award of the Royal medal. Of separate works may be noticed a volume on the Conway and Britannia Tubular Bridges (1849), including his researches on the best form and strength of wrought-iron beams; a work 'On the Application of Cast and Wrought Iron to Building Purposes' (in 1854 and 1857); and a valuable compendium, entitled 'Useful Information for Engineers' (in 1856 and 1860). Perhaps it may be said with truth that there is no single individual living who has done so much for practical science, who has made so many careful experimental inquiries on subjects of primary importance to the commercial and manufacturing interests of the country, or who has so liberally contributed them to the world. Mr. Fairbairn, in presenting this medal to you from this Chair, I will venture to say that the award of the royal medal—the medal which her Majesty the Queen has been graciously pleased to place at the disposal of the President and Council—for scientific services such as yours, so eminently conducive as they have been to the general good, is even peculiarly appropriate."

THE LITTLE EASTERN.—A model of a steamship, propelled on a new principle, invented by Mr. Robb, of Glasgow, and christened as per title, was exhibited in the City Hall of that town recently. The propulsion of the vessel is effected by an apparatus placed at each side of it and at the stern, the idea being apparently borrowed from the fins of a fish, or rather the web-foot of a duck. The model is about 2 ft. 10 in. in length, and the stroke 1¼ in. It was placed in a trough 25 feet long, erected on the platform, and made the passage from one end to the other in about 15 seconds. The machinery is moved by springwork, merely to illustrate the principle of the new direct acting propellers, which, Mr. Robb avers, can be worked at a fourth of the expense of paddle-wheels.

DESTITUTION AMONGST THE WORKING CLASSES IN LONDON.—It is estimated that there are at present 50,000 labourers out of employment, and with their wives and families starving. What a state of things in wealthy London—the golden store of the world!

New Application of Peat.—Some improvements in manufactures from peat have been patented by Mr. H. Hodgson, of Ballyreine and Merlin Park, and Mr. P. M. Crane, of the Irish Peat-works, Athy. The invention consists in preparing from peat, in its natural state, blocks, slabs, or pieces of any size, form, or thickness, which blocks, slabs, or pieces are said, when so prepared, to be useful and economical in the construction of parts of buildings and for other useful purposes. They place these blocks between cloths of woven or textile fabric, or other suitable material, and the peat is placed between shelves, and submitted to hydraulic or other pressure. The water is entirely forced out and the peat solidified, and drying is effected either by exposure to the atmosphere or in a room heated artificially, or by any other process. They are then put again between the plates of a hydraulic or other press, and extreme pressure put on them. If the product of their invention be required for use for inside work in building, such as partitions, linings, inside roofing, or for other work, as a non-conducting substance, they do not require other further preparation than shaping, provided they are not to be exposed to wet. But the slabs or pieces used for roofing (instead of slates, tiles, or other things of that nature) they prepare to resist the wet or action of the atmosphere by steeping them in, or saturating or coating them with, some fitting material.

To Soften Old Putty.—In removing old broken panes from a window, it is generally very difficult to get off the hard dry putty that sticks round the glass and its frame. Dip a small brush in a little nitric or muriatic acid—to be obtained at the druggist's—and go over the putty with it. Let it rest awhile, and it will soon become so soft that you can remove it with ease.

Muslins Rendered Fireproof.—Messrs. Versmann and Oppenheim, of London, whose researches have been most carefully and scientifically conducted, advise the use of the following solution as the only one which can be recommended for laundry purposes:—A concentrated neutral solution of tungstate of soda, diluted with water to 28 degs. Twaddle, and then mixed with three per cent. of phosphate of soda. This solution is found to keep and to answer well. It has been introduced into her Majesty's laundry, where it is being constantly used. It is stated to be neither injurious to the texture of colors, nor in any degree difficult of application in the washing process. Its protecting power against fire is said to be perfect.

The Universal Private Telegraph Company propose to establish in offices and elsewhere a means of privately communicating by telegraph. For this purpose they extend a rope, containing a great number of fine insulated wires, over the streets and houses, and any one of those wires may be rented. To render such arrangements practicable, it was essential in the first place that the wire connections should be effectually made at a comparatively small cost. This object is obtained by Mr. Silver's process for insulating wires, by coating them with Indian rubber. The wires are very much thinner than bell wires, and a rope containing upwards of 30 of them properly insulated is barely half an inch in diameter. The rope is fixed on poles at the tops of the houses, about 200 yards apart, and it is said that the company have experienced no difficulty in obtaining the consent of the occupiers to have the poles fixed on their dwellings. This arrangement is so economical that the company offer to let out each wire at the rent of £4 per mile per annum. The instruments to be employed are the magneto-electric telegraphs, invented by Professor Wheatstone, slightly modified.

The Electric Light.—The tall pyramidal scaffoldings erected at different points within Paris for the triangulation of this capital with its recent additions, having been found to oscillate to and fro from the constant traffic through the streets by day, it has been at length resolved to proceed with the triangulation at night, by means of the electric light; and experiments are to be made with the light itself, in order to discover some convenient means of applying it to the lighting of streets.——Professor Way, says the *Critic*, has discovered an electric light far superior to any yet known. It is produced by the action of a voltaic battery on a moving column of mercury. The mercury is contained in a crystal globe, of the size of an orange, and is sent from a very minute hole, under the form of a thin metallic thread; it is received in a small cup, whence it falls into a basin below, to be again conveyed to the globe above. No sooner are the wires of the battery in contact with the thread of mercury, than a vivid light is produced, which disappears as soon as the contact is interrupted. During this process no evaporation of the mercury is observable.——The old oil lights which have been in use so many years on the Portland lighthouses will (says the *Southern Times*) shortly be discontinued, the electric light being its substitute, the Board of Trade considering the Portland lights of so much consequence to ships going down or coming up Channel, these having to pass in close proximity to that dangerous place, the Portland Race.

Mr. Scott Russell and the Great Ship Company.—In the Court of Queen's Bench, London, Mr. Scott Russell applied recently to show cause why the arbitrators' award should not be set aside. It appeared that he was employed by the first company who were engaged in constructing the Great Eastern to do certain work to that ship. In the contract there was a clause for the purpose of referring any dispute which might occur to arbitration. During the continuance of Mr. Russell's contract the company was reorganised, and a new set of directors took the places of those who constituted the original board. A dispute as to the meaning of the contract then occurred, and the matter was accordingly referred to arbitration; the arbitrators found for the plaintiff in the whole amount claimed, which included alterations which were not mentioned in the contract; and a rule obtained to set aside the award on the ground that the arbitrators had no jurisdiction to deal with any matter not in the contract. Mr. Bovill contended that the arbitrators had a right to go into matters contained in the articles of submission, and that these extras fairly came within that deed. Sir Fitzroy Kelly contended that the arbitrators exceeded their power in dealing with the extras, as the contract contained the words, "there shall be no extras," and the same contract only provided for the reference to the arbitrators of those matters referred to in it. There were an immense number of affidavits filed on both sides, and the arguments upon them occupied a very considerable time. There was a cross-rule calling upon the company to show cause why they should not at once pay the amount recovered under the award. Their lordships decided that both rules must be discharged, and the parties left to their remedy at law by action on the award.

A New Question in Naval Warfare.—At a recent trial of the new Blakely gun it was remarked by some professional artillerists—foreigners—present, that as "such was the velocity of the shot that it did not touch the ground until it had passed 60 feet beyond the target, although the hole in the hamper was found to be not more than a foot from the ground, it might after all be better to build the bulwarks of a ship very light, and let shot pass easily *through both sides into the sea.*"

A person writing from Melbourne, Australia, says the mass of temporary buildings erected for the emigrants drawn there by the gold fever is fast being replaced by fine edifices for domestic and municipal use. Within the last three or four years, besides the public works undertaken by the government—among which are the Houses of Parliament, the Treasury, the printing-office, new Post-office and new government offices—large and splendid houses have been erected for the various banking corporations, that would discredit no large city. Among other notable improvements is the establishment of a well-furnished library in a handsome stone edifice. The Observatory is also a recent erection.

White Oak Timber a Substitute for Whalebone.—Many unsuccessful attempts have been made to obtain a perfect substitute for whalebone, in the manufacture of the ribs of umbrellas and parasols. An ingenious manufacturer has at last found that white oak timber of the second growth, when selected from the butt-end of the tree, and straight and free from knobs, may, after subjection to a certain curing process, be employed as a substitute for whalebone. It is even said to be superior to whalebone in toughness and tenacity, and the ribs made from it always resume their original straight condition after exposure to the weather.

Galway Harbour.—At the special sessions recently held for the barony of Dunkellin, the following resolution was carried unanimously:—"Resolved—That the magistrates and cesspayers of the county of Galway deeply deplored the rejection by the House of Lords of the provisions in the Galway Harbour Bill (1860), by which the guarantee of this county for securing the necessary funds for the improvement of the Port and Harbour of Galway were proposed to be legalised; and that we hereby declare our readiness to give the said guarantee of one penny in the pound on the valuation of this county for securing the sums required for the improvement of the harbour and port of Galway, by the formation of a pier, breakwater, and of graving and other docks, and we trust that in a future session such a proposition may receive the sanction of the Legislature."

The Barravore Lead Mining Co. held a meeting recently to dissolve and wind up. The undertaking appears to have eventuated in an almost total loss.

NOTICE.

Post-office Orders and Remittances should be made payable to Mr. Peter Roe, *Printer and Publisher*, 42, Mabbot-street, Dublin.

☞ *NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the* Dublin Builder," 42, Mabbot-street. *All other Communications should be addressed to the "Proprietor and Editor,"* 17, Lower Gardiner-street.

Iron Founders, Plumbers, &c.

NEW BALANCE ROLLING BRIDGE.
KENNY'S PATENT.

The undersigned beg to call the attention of Engineers and the Public to the above description of Opening Bridge, as now being constructed for the entrance to the St. George's Dock, Custom-house Quay, Dublin, for the Board of Works, which will be found superior to the ordinary Swivel Bridge, both in point of simplicity of Construction and Cost.

Plans and Specifications furnished, and Licenses granted on application to

TURNER AND GIBSON,
Proprietors and Manufacturers,
HAMMERSMITH IRON WORKS, BALL'S-BRIDGE,
DUBLIN.

KITCHEN RANGES, Drawingroom Bright Grates, Fenders, Fire Irons, and all kinds of Builders' Ironmongery. MAURICE BROOKS, SACKVILLE-PLACE, Dublin.

WILLIAM TURNER,
OXMANTOWN FOUNDRY & IRON WORKS,
103, NORTH KING-STREET, DUBLIN.

Cast-Iron Girders, Plain and Ornamental Pillars, Moulded and Plain Gutters, Tank Plates, Gas Retorts and Pipes, Kitchen Range Work, Millwright, Castings, Balconies, Brackets, Staircase Ballusters, etc., supplied. A large variety of Models for the above in stock.

HOUSE-FURNISHING IRONMONGRRY & GAS-FITTING WAREROOMS,
34, 35, & 36, *CAPEL-STREET.*

JOSHUA EDMUNDSON AND CO., Manufacturers of the Patent Gas Apparatus for Lighting Noblemen's and Gentlemen's Country Mansions, Mills, Colleges, Country Towns, &c.

Agents for Milner's Fire Proof Safes and Boxes; Goddard's Patent Cooking Apparatus; Bradford's Washing and Wringing Machines; Atkinson's Chimney-tops, &c.

34, 35, & 36. *CAPEL-STREET, DUBLIN.*

HAMMERSMITH IRON WORKS, DUBLIN.

MESSRS. TURNER AND GIBSON, Manufacturers of IRON CONSERVATORIES, Fruit Houses, Pine Pits, etc.

Ornamental Works, Bowers, Porches, Balustrades, Trellises, Flower Stands, Vases, etc.

Grand Entrance Gates, Guard Railings, Farm Gates, Hurdles, and Strained Wire Fencing, etc

Iron Roofs for Railway Stations, Breweries, Gas Works, and Farm Buildings, etc.

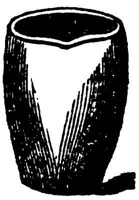
Warming & Ventilating Dwelling Houses, Prisons, Conservatories, Mills, and Public Buildings, etc.; House, Laundry, Cooking, and Steaming Apparatus.

Bridges, Girders, Iron Lattice, Bowstring, Suspension, Patent Balance Rolling, and Swivel Bridges, and Floor Girders

T. and G. beg to refer, as specimens of *their work*, to the Iron Conservatories, Heating, etc., as erected at the Royal Botanic Gardens, Kew; the Inner Circle Botanic, Regent's Park; Cheltenham: Viceregal Lodge; Glasnevin; and various Works by them throughout the United Kingdom.

TO BUILDERS.—TO BE LET, in RATHGAR, on the Roundtown road, about 500 Feet of BUILDING GROUND, 260 feet from front to rere, at 4s. per foot. Also, in Rathgar-avenue and Beauchamp-avenue, 2,000 feet at 3s. per foot. Lease 999 years. The situation is unquestionably the best in the suburbs of Dublin. Apply to Dr. Beauchamp, 115, Baggot-street; or to F Armstrong, Builder. Baggot-street.

TO BRASSFOUNDERS, ENGINEERS, REFINERS, ETC.



THE PATENT PLUMBAGO CRUCIBLE COMPANY beg to call the attention of all users and shippers of Melting Pots to the great superiority of the PATENT CRUCIBLES, which have been used during the last three years by some of the largest melters in England and abroad. In addition to their capabilities of melting an average of from thirty-five to forty pourings, they are unaffected by change of temperature, never crack, but can be used till worn out, requiring only one annealing for several days' work, and become heated much more rapidly than ordinary pots, effecting thereby a saving of more than fifty per cent. in time, labour, fuel, and waste. The Patent Plumbago Crucible Company also manufacture and import clay crucibles, muffles, portable furnaces, sublimate pans and covers, glass pots, all descriptions of fire-standing goods, and every requisite for the assayer and dentist.

For Lists, Testimonials, etc., apply to Battersea Works, London, S.W.

Statuary, Marbles, Cements.

TO BUILDERS, CHIMNEY PIECE MANUFACTURERS, &c.
PURE ITALIAN MARBLE, DIRECT FROM THE QUARRIES.

The Subscribers now offer to the trade a choice assortment of White Veined Marble Slabs—of various sizes—which they will dispose of at reduced prices to close sales.

H. and W. SCOTT,
31, EDEN QUAY.

TO ARCHITECTS AND GENTLEMEN HAVING MANSIONS IN COURSE OF ERECTION.

JAMES HOGAN AND SONS,
Stucco Plasterers, General Cement Workers, Modellers, &c.,
168, GREAT BRUNSWICK-STREET,

Beg leave to state that they are prepared to undertake Contracts in the above line. Ornaments for Cornices and Centre Pieces for Ceilings supplied. Fronts for Houses done in Portland or Roman Cement at first cost price. Country Orders strictly attended to, and first class workmen sent to all parts of the Kingdom.

BEST CEMENTS.

ROMAN CEMENT, PORTLAND CEMENT, and PLASTER PARIS STORES,
10, Sir John's-quay, Dublin.

George Holmes and Co. are constantly supplied with the above materials of genuine quality, direct from the best manufacturers. Also Sewerage Pipes, Junctions, Bends, &c.

CHIMNEY PIECES—in Italian, Belgian, Irish. and English Marble; Enamelled Slate, and Cast Iron: suitable for Drawing-rooms, Dining-rooms, Bed-rooms. &c. A very large Stock to select from. MAURICE BROOKS, Sackville-place, Dublin.

IMPORTANT TO THE PUBLIC.

THE IRISH WASHING MACHINE
FOR THE MILLION,
Provisionally registered on the 1st of November, 1860.

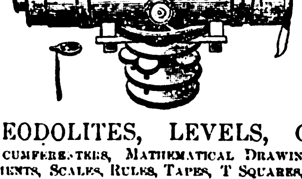
"The perfection of Machinery consists not in a complication of appliances, however beautiful, but in rigid simplicity."

This Machine has been fully tested and approved of, will be put in competition with any of the kind brought before the public, being more simple, cheap, and effective, and washing with more safety to the clothes; the internal machinery for possing and raising a lather can be made of glass and covered with muslin; it is calculated to effect a saving of half the labour, soap, and fuel, used in the ordinary way of washing; there is no iron in the construction; will not be liable to get out of order; can be made to any size to suit families and public institutions; a twelve-foot plank will make a size to suit twelve in family, be as durable and nearly as cheap as a common wash-tub, and occupy so very little space, can be placed in any convenient apartment. A lady may become her own laundress, as the process can be got through by very gentle exercise, with safety to the most delicate hands.

It is deemed to be of such public utility. and so highly calculated to promote cleanliness, the Proprietor is desirous of making it available to the community at large, and is therefore prepared to appoint Agents in every town in the three kingdoms, to dispose of the *Design*, with directions for making and using it, at 2s. 6d. each, merely the cost of bringing it within their reach, and need not pay until satisfied of its utility.

Philanthropists are respectfully solicited to become Agents: terms liberal.

Address JOHN KELLY, C.E., Brook Lodge, Roscommon.



THEODOLITES, LEVELS, CIRcumferentres, Mathematical Drawing Instruments, Scales, Rules, Tapes, T Squares, &c.

JOHN ARCHBUTT, 20, Westminster Bridge Road, Lambeth. near Astley's Theatre, respectfully calls attention to his Stock of the above articles, manufactured by superior workmen. The prices will be found considerably lower than ever charged for articles of similar quality. An illustrated price list forwarded free on application. 8-inch Dumpy Level complete, 6 guineas; 10-inch ditto, 8 guineas; 14-inch ditto, 10 guineas; with compass, 1 guinea each extra. Best 5 inch Theodolite, divided on Silver, 18 guineas.

Auctions, Sales, [illegible]

Auction of Wood Goods.

JOHN MARTIN AND SON WILL OFFER BY AUCTION, on THURSDAY, 28th February, Instant, SEVERAL CARGOES of BALTIC and NORTH AMERICAN TIMBER and [illegible], including

18,000 Pieces of very superior Spruce [illegible] now landing ex "Eugenie."

Timber by Auction.

TO BE SOLD BY AUCTION on MONDAY, the 18th of February, at PALMERSTOWN HOUSE, County Dublin, the residence of the late Lord Donoughmore, 500 TREES, consisting of Oak, Ash, Elm, Beech, and Aspen. Sale to commence at Twelve o'clock. This Sale will be found well worth the attention of the Trade, as the Timber is of superior quality and large dimensions. Some of the Elm and Beech will square from twenty to thirty inches in long lengths, and clean. The usual Auction Fees to be paid by the Purchaser.

JAFFRAY BARCROFT, Broker & [illegible],
42A, Great Brunswick-street.

Publications.

ARCHITECTURAL PUBLICATION SOCIETY.

THE DICTIONARY OF ARCHITECTURE.—Some of the early parts of this important Work are Out of Print, and unless the Committee shall be justified by the immediate accession of a sufficient number of new Subscribers,—in reprinting such parts,—the Plates will be destroyed. They, therefore, invite all who may desire to become Subscribers, to communicate such intention without delay.

For Notices see *Builder* and *Building News* of February 2, and the Dublin Builder of Feb. 15.

ARTHUR CATES, Hon. Sec.
9, Conduit-street, Hanover-square, W, Feb., 1861.

Just Published, Part I., Price Three Shillings.

EXAMPLES OF LONDON AND PROVINCIAL STREET ARCHITECTURE, of the Victorian Age, accompanied with Descriptive Notices, and also with Original Articles and Designs, Reviews, Correspondence. and Occasional Examples of Modern Buildings in the Streets of Colonial and Foreign Cities.

London: Frederick Tallis, 21, Warwick-square, Paternoster-row, E.C.; and all Booksellers.

TO TRADESMEN.

A PAMPHLET ON THE BUILDING AND OTHER TRADES, including Turn Outs, their causes, results, and remedies,
By Thomas M'Anaspie.

Published by McGLASHAN and GILL, Dublin; Simpkins, Marshall, and Co., London; John Menzies, Edinburgh. Sold by all Booksellers.

Price FOURPENCE.

MESSRS. ISAAC & W. R. FARRELL,
ARCHITECTS, ETC.,

Beg to inform Builders and others that they have added a Measuring and Valuation Branch to their Office, for which they have secured efficient Assistants, to enable them henceforth to supply Estimates, Valuations, and Measurement of Artificers' Works, as formerly carried on for many years by Mr. Isaac Farrell, of this Firm.

Office—25, LINCOLN-PLACE.

TO CONTRACTORS.

MR. WM. DOOLIN, Building Surveyor and Measurer, is prepared to afford Contractors all information as to prime cost on all material; take out Quantities, and prepare Estimates.—Offices, 27, TALBOT-STREET.

MESSRS. JAMES & EDWD. BARKER,
CONTRACTORS
To Her Majesty's War Department, and the Ecclesiastical Commissioners for Ireland.
All orders executed to satisfaction.
32, UPPER ABBEY-STREET, DUBLIN.

W. MAXWELL,
Architectural Engineer and Architect,
BALLINASLOE.

MESSRS. TELFORD & TELFORD,
ORGAN BUILDERS.

Several new and second-hand FINGER & BARREL ORGANS, suitable for Church or Chamber, will be sold on very reasonable terms, to make room.

109, STEPHEN'S GREEN, DUBLIN.

The Dublin Builder.

VOL. III.—No. 29.

PERPETUAL MOTION.

WHO amongst the community of "an inquiring turn" has not at some time of his life romanced on a prospect, "looming in the distance," of "immortal memory" being acquired by the happy discovery of that mystified object, "Perpetual Motion?"

Some more ardent than the rest—nay with fanatical zeal—pursued the phantom till physical and mental strength became exhausted, and nature sunk beneath its labours without the consummation. Others, *a fortiori*, prudently halting after numerous unsuccessful attempts to storm the breach, and deeming it impregnable, made "virtue of necessity," and retraced their steps. Philosophers, mechanics, and "very fools too," have each tried their hand; victory was frequently declared, but failed in confirmation, and the problem submitted for solution centuries ago, still remains a mystery. *If* the unravelling of this Gordian Knot *be* possible—*we* dare not express an opinion thereon, not being amongst the experimentalists or enthusiasts in any of the above capacities—judging from the earnest desire manifested for its attainment, we must confidently rely—however discouraging antecedent trials—that "*labor omnia vincit.*" Be the result, however, what it may in this and succeeding ages, the present generation *does*, and the future *will*, as surely regard the subject with infinite interest, and pursue its history with like feeling as heretofore. Until very recently where was this history to be found? unless, indeed, amongst the ponderous tomes and musty files of Chancery-lane, with an occasional record of the most recent "*wonderful discovery*" in a stray newspaper. Here, indeed, was a want, and who would volunteer the Herculean task of collecting the scattered fragments? A spirit, however, sufficiently chivalrous at length appeared, and before us lies the result in a presentable volume, *plena laboris*, illustrated by numerous diagrams.

"PERPETUUM MOBILE, or *search for self motive power*, during the 17th, 18th, and 19th centuries," is the title of the work in question; Mr. Henry Dircks, C.E., the author, and Messrs. E. and F. N. Spon, of Bucklersbury, London—a highly respectable firm, to whose enterprise the architectural and engineering professions, as also the general public, are much indebted for some standard volumes—the publishers.

The author, in a comprehensive introductory essay, proceeds to describe the sense in which the term *Perpetuum Mobile* should be taken in its mechanical application, admitting it is capable of modification, and should not be construed too literally, remarking that,

> "Being thus accepted as one early, yet wrongfully, though popularly applied, it distinguishes inventions intended to be operated through the medium of their own peculiarly constructed internal arrangements, and seems afterwards, though improperly, to have been extended to ingenious automata, worked by external agents, as *magnetism*, &c.; which latter we reject entirely."

We would endorse the propriety of this rejection, especially in the case of *water* (presumed to be included in the etcetera) being adopted as a motive power, its evaporation proving fatal both in theory and practice, as also as regards "*air*," for obvious reasons, but we are not disposed to go quite so far in the matter of *electricity* or *magnetism*. However, we shall not now enter fully on this abstruse question, but referring to the former we must note, that amongst the numerous mechanical appliances invented for the attainment of "*perpetual motion*," those into which the elements of "air" and "water" entered, seem to approach feasibility the nearest, as long as the motive power is *supplied*, but when it fails, as *infallibly it will* at *some* time, the apparatus ceases to act, and consequently the theory becomes exploded. A popularly adopted principle by experimentalists, but tortured into an infinity of shapes and forms, is that of the "ever counterbalancing weight applied to the rotation of a wheel;" referring to this our author remarks that—

> "Any machine would deserve the distinctive character of being a perpetual motion that acquired its rotation, supposing it to be a wheel, from a property consequent on the arrangement of its external parts, always compelling one side to become heavier than the other; such motion being no other than the ability in a machine to generate and maintain its own power of movement." "The attempts to solve this problem would seem so far only to have proved it to be thoroughly paradoxical. The inventions resulting from it during the last three centuries baffle any attempt at classification, developing progressive improvement."

Upon this however, the author's opinion seems to vary somewhat, as he illustrates the inventions of the Marquis of Worcester, and of Councillor Orfyrreus, as "justifying an apology for the pursuit of perpetual motion;" adding, "that the upright character of the noble inventor of the steam-engine affords proof against likelihood of falsehood, and will go far to maintain doubts respecting the infallibility of all mathematical demonstrations adverse to the possibility of a self-motive power;" further that "in a mathematical point of view, we think this subject is far from being exhausted; and after what has been advanced may very properly be regarded as claiming grave consideration." The inventions above alluded to are stated to be "the only two accepted cases, but both prove secrets"—the latter resulting from the eccentricity of the inventor, who made and destroyed in succession four wheels or machines alleged to have attained the object; a misunderstanding arising subsequently between him and a princely patron, "causing the subject to lie dormant, and the invention to die with him." The particulars of the respective apparatus are briefly thus: that invented by the Marquis was a self and perpetual moving wheel 14 feet in diameter, rotated by the action of forty 50 lb. weights; and that by Orfyrreus, his fourth, or last, also a wheel 12 feet diameter, 14 inches broad, made of light oak framing, and covered with oilcloth, revolving *either* way, and with power sufficient to raise 70 lbs. weight to a considerable height.

If we are to attach any importance whatever, to the published accounts of the successful attainment of the object in question by these, the question of practicability is so far decided. Amongst the very numerous illustrations or specifications we perceive one by an old and respected fellow-citizen, with which by a curious coincidence we were ourselves associated many years since, though repudiating any claim either for credit or the reverse as regards the invention department. It was that of the late Plato Oulton, enrolled in 1854, and comprehending a "machine in which a stream of leaden or other suitable balls are made to supply the place of water, in actuating two or more main wheels, and in which provision is made for keeping up a constant supply or stream of balls to these wheels, by means of *head* and *tail* races and a peculiar arrangement of worm shafts." It *may* be that "Plato thou reasonest well" in theory, but we are free to confess with the author, that a reasonable assumption is suggested that the races named must ere this have in practice proved "a goose chase," and a very "wild" one too. While unquestionable mechanical ingenuity and originality of conception are displayed in *some* of the "attempts" herein described, others—though not altogether lacking the *latter* element, and in some instances to a vengeance possessing it—are pitiable exhibitions of delusion.

Reviewing in the abstract the *Perpetuum Mobile*, it is a book from which the reader may simultaneously derive recreation, wholesome caution against fallacies to be avoided in pursuit of what *as yet* has proved to be mythical, and likewise suggestions possibly serving as a stepping-stone to the future development of the means, *if at all* capable of accomplishment. The author in laudable spirit undertook his task, he has pursued it earnestly to completion, and may justly view both the retrospective and reality of his mission with much pride. We trust that the result will prove substantially remunerative.*

---

* PERPETUUM MOBILE, or *Search for Self-motive Power* during the 17th, 18th, and 19th centuries, with introductory essay by Henry Dircks, C.E. London: E. and F. N. Spon, Bucklersbury.

AGGREGATE MEETING RELATIVE TO "THE WATER SUPPLY."

On 25th ultimo a most numerous meeting took place in the Rotundo with reference to this still *quæstio vexata*, and in obedience to the call of the Lord Mayor, who presided on the occasion. His lordship made some brief introductory remarks on the purposes for which the meeting was convened; the history of the movement for securing an improved supply; the appointment of the Royal Commissioner Mr. Hawkshaw; his report; and concluded by an appeal to all parties, however opposed in opinions, to discuss the question calmly. Dr. Gray followed, and was greeted with general applause—a compliment at this stage of the proceedings judiciously bestowed—fully illustrating public appreciation of his eminent devotion to, and his pre-eminent capability to deal with, this important subject. His statement occupied a lengthened period in delivery, refuting the alleged erroneous accusations made against the promoters of the measure now before Parliament, their general proceedings in connection therewith, as well as those of the Opposition Committee; the financial features, especially those referring to municipal taxation; its present unequal distribution on the rich and the poor; the position occupied by Master Fitzgibbon, who wrote a pamphlet of 53 pages against the Corporation, &c.

Mr. Benjamin Lee Guinness, whose rising was the signal for great applause, after some pithy and pertinent remarks proposed the first resolution, which was as follows:—

> "Resolved—That this meeting are of opinion that the Corporation of this city would have failed to perform their duty to the city, and would not have redeemed their pledge to abide by the recommendation of the Royal Commissioner, had they not introduced a bill to carry into effect the report and recommendation of the Royal Commissioner."

Mr. Codd seconded the foregoing, and urged that the Royal Commissioner should in common courtesy be sustained; and concluded an able confirmation of Dr. Gray's and Mr. Guinness' previous statements.

Professor Webb, as a member of the Opposition Committee, stooped to pick up the gauntlet thrown down by Dr. Gray, and maintained that the fact of the *large expenditure* to be incurred *violated the pledge* entered into with the Royal Commissioner by the Corporation and the city members. That pledge was that they would support any scheme which the Commissioner recommended, *provided the cost did not exceed from* £250,000 *to* £300,000. There was not a gentleman present would stake his character upon the assertion that £300,000 would cover the whole of the expenses. Many gentlemen had openly proclaimed their belief that £500,000 would not do, and if he were to express his belief, it would be that of Master Fitzgibbon, that before the works were consummated the cost would reach a million. He agreed with Dr. Gray that it was an unjust theory of taxation that the house rated at £5 and at £10 should pay the same amount, and that there ought to be a poundage rate; but he believed it was not true to say that the opponents of the bill were disposed to disregard the rights or claims of the *poor*, or to favour the *rich* at their expense. He was not in favour of unequal taxation, but he protested against a scheme that would introduce unlimited expense, and which would entail unlimited taxation. When the trade and business of the city was already overburdened with taxation, what would become of it under the additional taxation caused by this bill?

Colonel LaTouche said that it would be presumption in him to give any opinion on the engineering question; but on the *quality* of the water he was a competent witness, for all *his life he was in the habit of frequenting the Vartry*, and he could say that in a dry season, particularly at the Waterfall at the Devil's Glen, there *was not water enough to fill a four-inch pipe*. Then it was a *mineral* district, abounding in manganese, lead, copper, and iron. There had been occasions, when he had seen the water *as red as blood*; and again, he was certain that the supply of water required to keep full the spacious reservoir which would have to be constructed, and from which there should be immense loss by evaporation alone, would fail altogether in dry seasons.

Dr. Wilde, in proposing the next resolution, stated he had come there to impress upon them one great fact, that there was wanting, sadly wanting, to this city and to the citizens of all classes, water, *pure water*, and plenty of it, for public and domestic purposes. He denounced the canal water as impure, as did professors Apjohn and Donovan. If possessed of the wherewithal, he might have a choice of many sort of beverages, from a draught of sparkling champagne, rich Burgundy, or cool claret, to a pennyworth of swipes, or surely if athirst, he would not grudge his twopence for a small bottle of Guinness's double X. (laughter). But where was there a draught of pure, sweet, and wholesome water to be had? No where. They should remember that it was not for themselves alone they were seeking this priceless advantage, but for their children, and children's children, who would bless them in days to come for the means of health and comfort thus secured to them. He concluded by proposing the resolution as follows:—

> "That, for domestic and sanitary purposes, and for the more effectual preservation of life and property from fire, it is imperative that the water should be delivered at high pressure and on constant service."

Dr. Rawdon M'Namara, the seconder, said that, as a medical man, connected intimately and professionally with every question involving the well-being of a large section of the poor of Dublin—having charge of an extensive district under the poor law, inhabited by a dense population of the humblest poor; he felt it to be his bounden duty to declare his own experience of the insufficient way in which water was obtainable by the poor. He could say that the water supplied to that large class of people was *bad in quality*, *insufficient in supply*, and obtainable only at the expense of *great inconvenience*, *loss of time*, and *detriment*. It was his opinion, and he asserted it fearlessly, that the present wretched system of water supply, especially to the poor, was fraught with the elements of *disease* and *death*.

Professor Jukes would not say that it is impossible there could be mines in the valley of the Vartry; but can say that that valley is entirely separated from all the mining districts in which mining operations are going on by two other valleys—so that the only portion of the mountain district from which the drainage runs into the Vartry Valley is a small portion of the eastern side. But whether there be mines therein, I say it would be utterly impossible to devise any scheme whatever for getting water from Dublin, or any county in Ireland, to which the same objection would not equally apply.

Mr. James Haughton suggested that an expense of even £300,000 should not be incurred in trying to get water with the quality and abundance of which they were not satisfied. He called on the citizens of Dublin not to allow this bill to pass. *Perhaps* it was the *best* scheme, but at all events they did not know that, and he would conclude by saying to them *inquire, inquire*.

Alderman Reynolds addressed the meeting at considerable length, premising his observations that he was not so high an authority on *cold water* as his friend Mr. Haughton. They heard out Professor Webb patiently, and his speech would be reported fully in the opposition journals, interspersed with "great cheering," and "loud and repeated applause." Who gave that applause? The body-guard of young gentlemen whom he had brought with him from Trinity College—who were packed up in one corner, who cheered the professor during his speech, and when it was over made a rush out in a body, as much as to say we have done our work, and now we will go back to old Trinity and drink his health in a *draught of old October*.

Mr. Taylor—Will you answer this question? If on getting tenders for the works the corporation find the cost will exceed £300,000, will they pledge themselves to withdraw from the undertaking?

Alderman Reynolds—I will hand over the privilege of answering that to a better authority than myself, Dr. Gray.

Dr. Gray—If the estimates given in the bill, and deposited in the parliamentary offices, are not sufficient to cover all the works, the rules of parliament necessitate that the bill shall be thrown out upon that ground alone.

Alderman Reynolds—With regard to the pipes being able to bear the high pressure, said there were 80 miles of pipes for the conveyance of water through the streets. In eight years the corporation had laid down 18½ miles, at an expense of £1,000 a mile, and these—as had been tried by the maker in Scotland, and twice here,—were capable of bearing not only a pressure of 100 pounds to the square inch, which would be the maximum pressure required, but of bearing a pressure of 400 pounds to the square inch. But the professor might say that what was true of the 18½ miles of new metal main was not, therefore, true as to the remaining 60 miles. Mr. Crofton, inspector of water works, a practical man, of long experience in the city, informed him that when the old pipes were laid down the science of casting pipes of a slender description was unknown. The consequence was, that the old pipes were three times stronger than new ones.

After this speaker followed Dr. Waller at considerable length, as also Professor Sullivan, who proposed a resolution, and Mr. John Drew Atkin, who seconded same to the following purport:—

> That, in the opinion of this meeting, the water supply of the city ought of right to be vested in the elected Representatives of the Ratepayers, and it is satisfactory to observe that, while the Municipal Council seek to provide for the efficient supply of the City, they have also determined that the Tax shall be limited to a definite poundage rate.

The meeting soon after separated.

Enormous Anvil.—Messrs. R. Morrison and Co., of Ousburn, Newcastle-on-Tyne, cast lately an enormous anvil block weighing upwards of 34 tons, for the Elswick Ordnance Works. The melting of the metal occupied five hours, and the immense mass will take three weeks to cool, when it will be removed to its bed at Elswick.

NEW RAILWAY BRAKE.

At the last scientific meeting of the Royal Dublin Society, Mr. Henry Shaw exhibited a model of a new patent railway brake, invented by him, and also read a paper, from which we extract the following, descriptive of same, on the means or apparatus whereby a railway train in motion may be brought to a stop at a distance of from 50 to 70 yards:—

The mechanism which I submit to your attention is simple, exceedingly few in its parts, and most effective for the purposes intended. It is, moreover, inexpensive, and may be applied to the existing rolling stock without disturbing a single bolt.

The wearing parts are but the ordinary wood pieces, which, as at present, are pressed against the peripheries of the wheels, with this advantage—that as the work to be done is distributed uniformly over every wheel in the entire train, instead of being confined to a few, each piece of wood will last the longer time.

Referring to a report made by Colonel Yolland, Royal Engineer, and one of the inspectors of railways in the year 1858, upon the subject of brake power, and which report was directed by the Lords Commissioners of the Board of Trade to be laid before the respective railway boards in the United Kingdom, that eminent engineer gives it as his opinion "That the amount of brake power habitually supplied to railway trains is in most cases insufficient to prevent the recurrence of accidents." That is, brake power applied to but one, two, three, or four carriages in a train of eight or more, is but a small percentage of what ought to be employed.

In this apparatus you will observe that I have provided a brake to every wheel in the entire train of carriages, and that my means or apparatus for actuating them simultaneously is effective.

Colonel Yolland adds—"It is essential to the safety of a train travelling at a high rate of speed that the engine-driver should have power to stop his train after receiving notice of an obstruction." And again, that "it is desirable, in order to prevent *unequal* pressure upon any one part of the train, that the force employed to check the speed of a train should be, as far as possible, distributed throughout the train." Also that "It is essential that the rere of a train should be protected with brake power to prevent carriages from running back on inclines in the event of couplings becoming detached or breaking. That the *entire* of the brake apparatus on the several carriages be communicated by *one man*, in order to secure *simultaneous* action."

Referring to some patent brake apparatus which in that year was submitted to his experiments, he says:—"Without expressing an opinion that Messrs. Newall and Fay's brakes are superior to other brakes, I find that as many as *four* carriages *under favourable* circumstances may be actuated."

It is much to be deplored that the valuable advice given by that able officer in 1858—a report of which was sanctioned by the Lords Commissioners of her Majesty's Board of Trade, and ordered by them to be laid before every railway company throughout Great Britain—did not meet with more attention.

Railway trains continue to be run daily, at fearful rapidity, with heavy brake vans swinging on behind. The brakeman is stationed at the rere of the train instead of in the front; and that which elicited from the Board of Trade such a warm approval, a distribution of the force throughout a number of the carriages, has been adopted only by a very few companies of late years.

It is but fair, however, to both Mr. Newall and Mr. Fay to state, that the means or apparatus for actuating the brakes on railway carriages, and invented by these gentlemen so far back as the year 1852, are mechanical and well arranged, and goes far to meet the purposes for actuating brakes on continuous carriages. The difficulty, however, had yet to be overcome, and that difficulty, I trust, I shall be able to satisfy you is now at an end.

The inertia of matter is that when it is at *rest*, and it is also called inertia when it (matter) is in motion. The force applied to matter to give or aid its motion is called *momentum*, and the force which is applied to matter to give it rest is called *friction*.

These laws, how well understood in theory, how much they have been departed from in practice. "The first false step leads to many a woeful sin."

When railways were first established, the weight of an engine was fairly commensurate with its power and strength; now-a-days they can't make them too heavy, because engineers have lost sight of the laws of matter—they seek to do that by *brute* force which more properly belongs to nature. Heretofore the carriages of a railway train were linked or coupled slack to each other, and the force applied by the engine in front gave momentum to the contiguous carriage, the weight of which, added to the engine, soon communicated it to the one next in order, and so on to the remainder, and in this way was the greatest amount of speed attained. Neglecting the order of matter, engineers screw up their carriages one to the other as tort as it is possible to do so. And what is the reason given for so doing? That when the brakes on the heavy brake-van swinging on behind are put on, that the force, so applied, be forthwith communicated to the carriages not so braked, and thus, as far as possible, get rid of dunting—that is, one rolling carriage knocking up against that which is braked.

To say nothing of the expenditure of building engines of twice the weight that is necessary, the injury to the road by the greater weight, or the cost of haulage of material (heavy brake-vans included), the practice of screwing up the carriages tort to the buffers is attendant with very great danger, particularly when passing at a high speed round curves.

The *modus operandi* of the present day for stopping trains in motion is by means of an enormously weighted brake-van at the rere of a train, and by means also of the tender in front similarly provided with brake power: the intervening carriages are left without any brake power. On some few lines of railway some two or three carriages are in connexion with the brake van provided with brakes, and by means of Messrs. Newall and Fay's apparatus these last-mentioned carriages are actuated. That engineers admit the principles as laid down in Colonel Yolland's report to be sound and reasonable, is proven by their partial adoption of these continuous brake apparatus, is true: that they have not carried these principles out in their entirety, is a proof that they have not given their attention and skill to the subject.

The *force* to be applied to bring a train to rest is *friction*, but our engineers of the present day misapply this force, the consequences of which are often attendant with fatal results. A heavy brake-van at the rere of a train in motion, if too suddenly checked at a time when the engine in front is under steam, causes a *disjunction* of the train, or if at a time when passing over curves, the centre carriages will leave the rails; but what is of habitual malpractice is the wheels of the brake-van being continually *skidded*—that is, stopped from rolling—and dragged along the line for a distance of from 600 to 1,000 yards, becomes super-heated on their parts next to the rails; an expansion of the tire and a breaking of the wheel results, so that, that law which has its uses, if properly applied to all the wheels of a train, permitting them to revolve, at the same time pressing upon the peripheries with a light and soft material—as wood—is, by its abuse, rendered most objectionable, and attendant with danger.

The brake block as applied now so generally, I might say universally, to the wheels of railway break vans and tenders, is an instance of how the "many will follow a crowd," and it is therefore with the greatest diffidence that I raise my voice against this adaption for breaking the wheels of railway carriages. It, however, appears to me that the brake-block as it is at present applied to the wheel is most objectionable, and that, in consequence, its application is necessarily limited. You are aware that in its most improved arrangement or fixing on, it slides upon a rod stretching from axle-box to axle-box, and is made to approach the wheel in motion at or about its centre.

If the wheel was motionless at a time the brake block was pressed against its periphery, I could easily comprehend there could be no better arrangement for locking it; but when the wheel to be stopped or impeded in its revolution must necessarily be taken as in motion, then it is quite another matter.

Immediately upon the moment of contact of the block with the wheel the resistance offered by the wheel, to be thus trammelled, is immense; the friction affords no assistance, but on the contrary gives great resistance, and an amount of mechanical arrangement, manual labour, and waste of time is expended before any sensible effect is produced.

Have you not experienced that if the chisel with which you are about to operate upon a revolving piece of any substance was not pressed against the work it would not be effective? and you may possibly also know that if by any oversight you allowed the chisel to touch the revolving substance below its centre, that the chisel was drawn from you, and in all probability to jerk out of your hands. Now you will observe that in the model of my brake I make it approach the wheel at a point considerably below the centre. Thus do I make friction available to my purpose. Instead of meeting with resistance, I am assisted—instead of being rejected, I am accepted.

I have friction absolutely at my control to give any amount of pressure upon the wheel, to take it off or let it on just as I desire.

You will observe that I move round the wheel upon a point outside or eccentric to the centre, the wheel moves on, and this arrangement of mechanism secures to me the improvement I require. So does it also hold the wheel virtually on both sides at the one instant.

I will now conclude, simply observing, that as I have followed nature's law, so am I indebted to her for the ease, grace, and curity with which I travel over the earth, incline or curved line offering no impediment. There cannot in the least degree be *dunting* or knocking you about in carriages ; collisions with other trains is not to occur, and that odious practice of skidding wheels and loosening of tires is gone for ever.

The control of the engine, as well as that of the brake on every wheel of the train, is with the conductor in front.

The connexions may be formed in a moment, and the variety of rolling stock by the interchange of carriages of other lines in no way impedes their proper action.[*]

EXPLANATION OF THE ILLUSTRATION.

Fig. 1 is an elevation, showing the brake on each side of the wheel, and according to the direction the train is going, by the rotating of the brake-rod, is drawn to either side ; the centre on which the brake moves being eccentric to that of the wheel, the toe of the brake comes rapidly in contact with the wheel, the revolution of which assists the brake to go on. In ordinary use the toe of the brake never comes in contact with the rail.

Figs. 2 and 3 show elevation and section of the brake-rod, which is carried longitudinally underneath the carriage body, and upon which being rotated the screw traverses a transverse rod, which, in connexion with the guide rods attached to the brakes, actuate them.

Figs. 4 and 5 are elevation and section of a tubular rod for connecting the brake-rod of one carriage with the one contiguous. It is rectangular, with its aperture at each end, and which rectangle apertures are at right angles with each other, by which vertical and lateral play is afforded to the carriages, as well as that it gives ease when rotating the brake-handle, which may be any where on the train.

MR. S. SMIRKE'S LECTURES AT ROYAL ACADEMY.

FROM a series of lectures recently delivered by this eminent architect and scholar, at the Royal Academy, we quote the following:—

Fashion.—The leaders of the *ton* in the fourteenth century bethought them to prolong the toe of their shoes to an inordinate length. The servile crowd of imitators followed ; the passion grew with the growth of this superfluous appendage, till we find that by the middle of that century the toes of any well-dressed gentleman were tied up to his waistband. Again, some unsightly excrescence is supposed to have suggested to the coiffeur of Louis XIV. a structure of artificial locks, and not many years had elapsed after its adoption before the heads and shoulders of all Christendom were oppressed by the superabundant load of adscititious hair.

Judgment in arranging Colours.—In the distribution of coloured materials regard should be had to the retiring and advancing qualities of colour. Thus white, and bright yellows, and bright reds, appear to stand forward, whilst black, blue, and greys retire. Care should be taken not to outrage those prejudices of the eye ; for example, when dark and retiring colours prevail at the lower parts of an architectural composition, and the upper parts are of bright-coloured materials, the latter will inevitably appear to advance and overhang the former, producing a false effect that cannot be agreeable.

Whitehalls innumerable.—Our ancestors correctly appreciated the cheerful character of white by frequently designating halls erected for festive purposes Whitehalls. The hall at Kenilworth Castle was called the " whitehall." There was a " whitehall" in the Old Palace of Westminster ; and the Whitehall of Charles's intended palace is familiar to us all. There is also a " whitehall" in the Royal Palace at Berlin. Even our cousins across the Atlantic have taken over with them the tradition, and they have their " whitehalls" for festive and popular gatherings. It is a fact, and not without interest to any true-born Londoner, that the lofty building called the White Tower, in the mediæval citadel of this port of London, seems likely to owe its name to having been whitewashed externally. In a very fine illuminated manuscript of the fifteenth century, preserved in the British Museum, a carefully executed view of London is introduced, in the foreground of which appears this great fortress, and while the general masonry of the building is coloured naturally, and in a somewhat low tone, the tower, with its four angle turrets, stands out prominently and conspicuously white. So marked is the distinction that it cannot have been so represented in the manuscript without a special purpose, which was probably that of identifying the building.

The Poet and the Architect—I am very sensible that there is a vast, an almost incalculable, difference between the works of the poet and of the architect. The one has but his imagination to draw upon, whilst the other has to seek the materials of his work from a very different source, and too bold a draft upon his imagination would be the likeliest means of bringing his career to an untimely end. Still there is an analogy ; remote it may be, but real and, I think, manifest. I have said that I regard it as a principle of our art, in the treatment of colour in exterior architecture, that the colouring shall be consistent in character with the purpose of the building itself, and I have adduced various notable instances of the adaptation of colour to the nature of the building. The subject is, indeed, fruitful. I might easily adduce abundant proof to show that, as bright colouring has ever been regarded as productive of a gay and cheerful effect, so dark and sombre hues are equally effective in raising feelings in harmony with the grave and serious purposes of some buildings.

Decoration of Churches.—Even in the interior of a church it is, to my mind at least, open to question whether a true religious feeling is not better expressed by the grey, sombre tints of old stonework than by the gorgeous pageants of gilding and painting, inlaying and polishing, by which piety is supposed by some to be measured. Beautiful as are the St. Chapelle and the Church of St. Genevieve, at Paris, and the Hof Kapelle, at Munich, it is impossible not to regard them rather as æsthetic triumphs, than as evidences of the devotion of the builders It is very long since I saw the church of Sta. Maria Maggiora, at Rome, prepared for the midnight ceremonies of Christmas Eve ; but I have a vivid recollection of the enchanting effect of the bright polished marblesand the gorgeous gilding, the crimson satin embroidered banners, and the green festoons ; yet the impression produced on my mind was that I saw before me the most elaborately beautiful *salle a danser* in the world.

Expressiveness in Architectural Composition.—All objects that enter into the composition of a piece of architecture have some particular character which seems especially to belong to them, and which it behoves us to pursue. However, we may vary the treatment of them ; however much we may overlay them with ornament, we should be careful to do nothing calculated either to desguise or conceal their special character. Their motive and rational principle should be apparent and unimpeached ; and honesty and good taste alike demand that in the treatment of their details we should seek rather to display their purpose than to conceal it. Thus a column is a vertical support, and in designing a column its fitness as such should never for a moment be forgotten. Yet there is nothing, perhaps, which exhibits the waywardness of art more than a column. Its purpose is simple and obvious ; its duty is as apparent as it is possible for any architectural feature to be ; and yet it would seem that architectural ingenuity has been racked and tormented to devise modes of departure from that simple type which its mechanical duty seems to render so obvious. The Hindoo builder rests his weights upon fanciful and extraordinary compositions of animal and vegetable life. A similar barbarity was prevalent in Italy in the early mediæval period, when we see the shafts of columns poised most inconveniently upon the backs of monstrous animals.

Responsibilities of Great Masters.—The spiral flutes and beads suggested the twisting of whole shafts which are to be often found in early mediæval work, until at length the shaft altogether lost its character of a vertical support, and we find them coupled and intertwined and knotted, after a fashion more like ropes than cylindrical shafts of stone and marble. Raffaelle. in designing his immortal fresco of the beautiful porch of the Temple, incurred a grave responsibility in setting that example of spirally twisted shafts, to be too readily followed by those who knew not how to distinguish between the requirements of the painter and those of the architect. Had the composition been scored and cut up by the vertical lines of a number of ordinary columns, the effect would necessarily have been unseemly, and the painter was, therefore, tempted to give to them undulating forms which associated well enough with the accompanying figures. But it is worthy of note that this great master, when he worked as an architect, committed no such mistake as to give such substantial forms to real stonework. On the contrary, the few buildings with which he enriched our art are remarkable, even at that early period, for purity of form and propriety of design. M. Angelo by the caprices which he permitted himself to indulge in when he designed the tomb of the Medici, was little aware that he was paving the way to that monstrous progeny of broken pediments and other violations of propriety which often defaced the architecture of later schools. So his matchless contemporary, Raffaelle, by having traced on the walls of the Vatican those graceful contortions, so pleasing to the painter's eye, but so little adapted to execution in real stone and marble, may, perhaps, be regarded as the real parent of those fantastic masses of bronze and stone which are scarcely censured in the Baldachino of St. Peter's, the porch of All Saints' Church, at Oxford, and in a hundred other less distinguished localities.

Columnar Architecture.—At Liege we have it whimsically assuming the likeness of a gigantic baluster, an idea to which the quatro-centists of Italy had been also led by the loose rein which they were wont to give to their masonic fancies. At the Pavian Certosa we shall sometimes find their shafts divided into two distinct parts ; the lower part straight and normal ; the upper part degenerating into shapes fitted rather for confectionery than masonry.

---

[*] The inventor had the honour subsequently of submitting the model to His Excellency and Major-General Larcom, who are stated to have expressed their approval of its ingenious features.

Ivory, an architect of some merit, and greatly employed in the north of Italy during the seventeenth century, exaggerating the faults of the quatro-centists, devised columns of which the upper part is twisted, like those of his predecessors, whilst the lower part is bulged out into the resemblance of a baluster. Perhaps one of the most attractive variations is that where the shaft is enriched by superficial foliage, some ivy or vine seeming to clasp the pillar, and to twine its tendrils round the ponderous cylinder. Many such cases occur in the buildings of the quatro-cento period, and there is no denying their beauty, though we may question their architectural propriety. During the mediæval period those sculpturesque shafts may often be met with at Melrose Abbey, but in greater beauty and variety in Italy. These varieties may all, perhaps, be regarded as the natural offspring of the beautiful stems of candelabra which abound in Classic art, and where the most exquisite delicacy of foliage was often indulged in without restraint, and of course without violation of any architectural propriety. To the period of Renascent art, that period so original and so fertile (at least in its earlier phases) in quaint and picturesque devices, we may attribute the introduction of another curious irregularity in columnar architecture, namely, the building up of shafts in what are called rusticated blocks, sometimes alternately cylindrical and square, sometimes vermiculated, sometimes roughly hewn as from the quarry, sometimes in alternate bands elaborately carved in an endless variety of ways. Before quitting the subject of columns it is incumbent on me to take this occasion to express my unqualified condemnation of the practice, however common, of converting a single insulated column into a monument. Neither the undoubted Classical origin of this form of monument, nor the graceful proportions of the column itself, can be regarded as any justification of this manifest misapplication and perversion of a great architectural feature. Even our silversmiths have ceased to make Corinthian candlesticks, although the solecism still lingers among some competitive candidates for monumental street architecture. By how much we may admire the true adaptation of a column, in form and proportion, to its purpose of supporting a vertical pressure, by so much are we bound to condemn it when we find it standing idle and useless, or with no duty but that of lifting up to a dangerous eminence, and beyond the reach of distinct vision, some vase or other insignificant object, or some statue of a bulk and weight utterly disproportioned to the shaft of so colossal a pedestal. The very form of the capital at once betrays the impropriety of this application of a column. Whatever the style of art, whether Egyptian, Greek, Roman, Byzantine, or Gothic, the capital invariably spreads itself out to receive a burden pressing on it perpendicularly; the abacus in some shape is expressly adapted for the reception of that burden, and when the burden is not there, the abacus becomes unmeaning and superfluous.

AN ARCHITECT'S AUDIENCE.

A PAPER under the above title was read by Mr. Druce at the meeting of the Architectural Association of London, on the 15th ult., and from which we quote the following:—

"Our building is designed, the foundation is laid, and from that day it has an audience. Whom does it begin to attract as it slowly rises from the ground? Who stops to gaze—do any, and, if so, how does it affect them? Do they stop long and wonder what building it is? Do they take an interest in it? Do they pass again and again? Do they purposely come by that way to see how it is getting on, and, as it grows higher day by day, does it seem to give greater or less pleasure? Does it please those who look at it the more complete it gets? or does it seem to disappoint? Do those who looked at it at first no longer look at it? do they seem to say, 'I thought from the first few courses that it would be fine, but it is not so; now we see the meaning and finish of the design—it is spoiled'? Or does every one that has watched it throughout its growth, seeing it improve every day, seem impatient to have every scaffold-board and pole removed, and every hoarding down that obstructs the view, knowing that in that building, as in every perfect design, they, although pleased with every step, and the more pleased the higher it got, have not yet seen the building in its full mature perfection? No! not till the crowning finial is in its place—no! not till the very iron cross or gilded vane surmounts that finial and glitters in the sunlight. And when at last it is finished, and when the interlacing screen of the scaffolding, that so long tantalised and yet enticed the gazers, is gone, and the towers and roofs and windows come out clear to view—when the hoarding is down and the base and lower limbs, as it were, of the building, whereon the appearance of its stability depends, are exhibited, and the building, for the first time in its existence, seems to stand firm, clear, and independent, like a ship just launched into the sea, and for the first time freed from the restraining timbers—then, who cares for it?—what do the papers say?—what the public generally? What is said in the drawing-room?—what said in the club?—what in the architectural societies?—what in the offices? And after this, when foreigners come to England; when countrymen come to town; when students from the colleges visit the place; when antiquarians, the learned, the curious, are in search of objects for study and admiration, do they visit it?—do they write of it? And the poet, the seer, the man gifted with special powers of impression and expression, when he comes wandering by, spending hours in its cloisters or beneath its shade, does he sing of it? does it give him the frame whereupon to weave his more magical, more ethereal, but not necessarily more sublime creations? And in those after-times, when the artist and the poet visit its crumbling walls, is it worth painting? —is it worth recording? When architects visit it, is it worth sketching? is it worth measuring? is it, in whole or part, worth repeating?"

Referring to the various employers with whom an architect comes in contact, the author read:—

"I repeat these three classes of our audience, to show that the taste of the educated classes has had much to do with the simultaneous practice of the several styles, out of which stage, I think, we are passing. I think that for some time, if not always, we shall have to consider the requirements and tastes of these three classes of employers, and critics in broad principles, if not in a continuance of the details and easily recognised features of those separate styles, even although we arrive, as we evidently are tending to two styles which may merge in one—of a free round arched style and a free pointed style. The three marked characteristics of the Classical, Italian or Renaissance, and Gothic will long be looked for by their respective votaries—being the results of education, suitability to their respective habits of living and thought, as well as their architectural taste.

"These are some of the heads or main divisions of our audience, and until quite of late years they were the only classes that were capable of judging or of enjoying what was put before them, as much of the enjoyment of the buildings lay in the knowledge of their correctness. But I am thankful to say that our audience is extending day by day; and what do I mean by that? Do I mean that so many more people are educated by the numberless photographs, and the less cost of architectural books and plates? There is much in that; but what I do mean is this—that the masses of the people, whether educated or uneducated, have always been, and will always be, fonder of sculpture and painting than of architecture that depends as much as it can upon itself alone, and that it is only quite lately that architects, occupied by their surveying, their necessary business, and their measured proportions, or copied mouldings, have only just begun to be anything like as fond of it as the general public itself. You will now get an audience wherever the chisel rings—wherever you work bas-reliefs and interesting stories on your walls. Where such carvings as there are at the Oxford Museum, or at one or two churches now building, every one will visit you; where there is painting like that at All Saints, all will be attractive.

"You may please the classic student, if you will, with grandeur of proportion and severity of effect; the lover of mediæval architecture by solemnity; the lover of Renaissance by richness and luxuriousness; the man of business by careful and business-like arrangement of plan, and fittings, and boldness, and massiveness of style; the artist and poet by picturesqueness and poet thought; the workman by good work and skill: but depend upon it, in whatever style you work you cannot fail to win all these, and add to them the uneducated and the poor. If you find room in your capitals and your walls for rich and varied sculpture of sacred subjects and lives of great men, framed by the leaves of the wood and the flowers of the field, thus and thus only can we make the most sensitive among our audience—the poet—sing in far-off future of our works:—

"'Everywhere I see around me
The wondrous world of art,
Fountains wrought with richest sculpture,
Standing in the common mart;
And above cathedral doorways
Saints and bishops carved in stone,
By a former age commissioned
As apostles to our own.'"

An exhibition of works of the Society of Female Artists is now open at the Gallery, Pall Mall, and amongst the contributors are the well-known Madlle. Rosa Bonheur, Miss Raynor, Mrs. Burr, &c.

M. Hugoulin, an apothecary in the Imperial Navy, has discovered a mode of preserving impressions of footmarks or otherwise made in sand, &c. A thin iron plate, with lighted charcoal thereon, is placed over the impression; then an application of finely divided stearic acid, rendering compact the loose atoms, and subsequently of plaster of Paris, effects the preservation both of the original and supplies any number of moulds therefrom.

THE TOWNSHIP OF RATHMINES.

THE Commissioners for this important suburban district became incorporated in 1847, since which year, thanks to their enterprising spirit, the township has been rapidly improving, and is now the most important adjunct to the south wing of the metropolis. The roads are half as long again as they were at the above-named date; new avenues, squares, &c., have been formed, and are maintained in an excellent state of repair by a special body of men under the direction of the Commissioners' surveyor, Mr. Henry Johnston, C.E Again, other roads are projected, and two are at present in course of construction—one forming a connection between Ranelagh and Leeson Park, and the other through Lord Palmerston's grounds leading from a well-selected spot in Upper Rathmines to the new station lately erected on the Dublin and Wicklow Railway near Milltown. This latter is beautifully situated, commanding southern aspect and some fine mountain views, and will undoubtedly present most desirable sites for detached villas—a class of house very much needed in the township. We learn that overtures have been already made for several lots thereon, and doubt not that the project when matured will both prove a valuable acquisition to the township and amply recompense the railway company for their liberality in providing so great a public convenience as a station at the point in question. The wall enclosing a part of Lord Palmerston's property in Upper Rathmines from the roadway leading to the Dodder has been taken down and rebuilt, affording an additional width to the latter of about 20 feet, which previous thereto was, from its narrowness, most inconvenient both to equestrians and pedestrians. About 5 acres of his lordship's property has been taken by Thomas Drury, Esq., J.P., on which he is now erecting four handsome and costly detached villas. On the adjoining cricket ground Mr. Fawcett, now the possessor, is about to commence a large mansion. Amongst the others engaged in building in the township are Messrs. Davis, Chambers, Elvery, Roberts, &c., in Kenilworth-square; Messrs. Tiernan, Dunnill, and Draper, at Grosvenor-road; and Messrs. Collis, Gilbert, Johnston, Roberts, &c., at Leeson Park. A large extent of new and suitable sewers has been constructed, which effectually contribute to the sanitary welfare of the township, and moreover prevent the possibility of a recurrence of the former much-complained-of "under water annoyances" after autumnal rains. In 1847 there were but three houses for public worship, now there are *nine!* including the Molyneux (illustrated in this journal[*]) and the Roman Catholic Church on Rathmines road. Outside the Commissioners' boundary, at Rathgar, two handsome buildings for the Church of England and Presbyterian congregations respectively are in progress, and a Baptist Church is likewise in course of completion at Grosvenor-road, and a Roman Catholic do. on Rathgar-road, within the township. Nearly all available building ground has been taken. About seventy houses, some of fair architectural pretensions, were erected during the past year, and yet the demand for good dwellings exceeds the supply, and rents are on the increase.

Perhaps the only historic association connected with the town of Rathmines is a great battle, said to have taken place in August, 1649, between the Royalist army and the Parliamentarian forces, wherein the former, to the number of 11,000, under the Marquis of Ormonde were completely routed. Ludlow describes it as in his time encompassed with a wall 16 feet high, enclosing *ten* acres! but we are not aware that a single trace of this wall remains extant. The value of the property is increasing considerably and proportionately with the extent of the population from year to year.

The "water question" is just at present occupying much of the attention of the inhabitants and the Commissioners, the latter including several gentlemen of eminently practical minds; but we must postpone any reference to "the merits of the case" till a future occasion.

A FREE PUBLIC LIBRARY FOR DUBLIN.

A CITIZEN urges on the consideration of the Lord Mayor the propriety of adopting the necessary steps for securing the above most desirable object, submitting as a model that established in Manchester, and comprising a reference library of 30,000 volumes, four lending branch libraries, containing upwards of 22,000 vols., with public newsroom in addition to each; the library rate being limited to 1d. in the pound on the assessable property in the borough, producing £4,000. This institution is not open on *Sundays*, which would seem to cause much of its intended benefits for the working classes to be lost. In the town of Salford, which is as much part and parcel of Manchester as Rathmines is of Dublin, there is also a large free library, in connection with the Peel Park, forming a delightful sojourn for the public; so if the poorer inhabitants of Manchester, with such facilities as these, be not an educated class, who should?

INAUGURAL MEETING OF THE INSTITUTE OF CIVIL ENGINEERS IN IRELAND.

THE first general meeting of this body since its affiliation with the University was held on the evening of the 19th inst., in the New Museum building. Sir Richard Griffith, Bart., occupied the chair, and delivered an able and lengthy inaugural address, reviewing many matters of great professional interest, but chiefly referring to railway progress. He described the circumstances under which some of the principal lines were constructed, the great success which had generally attended such undertakings in this country, advocating the county or district guarantee system for assisting in the making of future branch and connecting lines, and spoke favourably of the tramways, which he stated would be highly useful if properly carried out in the places suited for them. In conclusion he referred to the fact that he had been upwards of fifty years performing public duties, and many years connected with important boards and commissions.

After the usual courteous ceremony the meeting separated at an early hour.

PROFESSOR DONALDSON AMONGST THE PYRAMIDS AND CATACOMBS.

THIS veteran architect, and one of the "fathers of *our* bar," has just returned after a tour of business and pleasure combined amongst the relics of ancient Egypt, and even in this the evening of his life he pursued—availing himself of a short leisure period—the investigation with the characteristic indefatigability and acumen of his palmier days. In a highly-interesting paper, read before the Royal Institute of British Architects, on the 18th ult., he referred to M. Marriette's excavations at Ghizeh and Saccara, the pyramids, the tomb near the great Sphinx, the serapeion of Memphis, Arab architecture, the catacombs at Alexandria, Pompey's pillar, &c., &c. A vote of thanks was accorded unanimously by the institute.

AN INDEPENDENT COMPANY (?).

MR. WM. HAUGHTON, the newly-elected chairman of the Great Southern and Western Railway Company, in the course of his able *resume* of progress and general affairs, when presiding at a recent general meeting of the shareholders, characterised "an independent company" as one *not* with plenty of cash in pocket, but more generally a company *independent* of cash, remarking that, "a few gentlemen meet together; subscribe a small amount of capital; call in an *engineer*, a *solicitor*, and a *contractor* to their aid, and *c'est tout fini*. The engineer takes a certain amount of shares, so does the solicitor, and the contractor is expected to take a large number of shares. He signs the parliamentary contract: it is understood that he is to get the contract for the work, and he is to be paid a schedule of prices precisely in proportion to the risk he incurs in taking the stock—viz., whether it is likely to be saleable in the market or not. They get an act of parliament; they scramble through difficulties for a few years, and ultimately the railway is opened in a very incomplete state with regard to public accommodation. And further claiming to be entitled to state a broad fact—namely, that not one of these railways made by *independent* companies has up to the present time paid even a moderate amount of dividend to its proprietors." On this principle there are many speculative insurance *schemes* projected, with this distinction, however, that "*the faculty*" is an indispensable ingredient in their constitution.

PAN-ORAMA AND *DIO*-RAMA.

A CORRESPONDENT asks us to oblige by a definition of the above terms.

The former is a picture exhibiting a succession of objects upon a spherical or cylindrical surface—the rays of light being supposed to pass from all points of external objects through the surface to the eye in the centre of the sphere or axis of the cylinder, and was invented by an English artist named Robert Barker, A.D. 1794; the latter a scenic exhibition on a flat surface, viewed through a proscenium, and light powerfully concentrated thereon, but capable of diminution at pleasure, while the spectators are left in comparative darkness. The diorama, by varied and ingenious contrivances, is capable of displaying the greatest difference in its pictures, and is especially adapted to the display of architectural interiors, moonlight scenes, sudden gleams of sunshine, &c., and was invented some few years since by two French artists, Daguerre and Bouton.

---

[*] See No. 16, Vol. ii.

WATER FOR THE *POOR* AND *RICH* MAN.

ONE of the best evidences that can be adduced in favour of a new bill for improved water supply to Dublin, financially regarding the question, is, that under the present *regime* a determined opponent to the new Corporate measure (submitted to Parliament for its sanction, and passed the second reading), occupying a mansion in Merrion-square, and holding a judicial appointment worth nearly £3,000 a-year, pays for water rate *two pence halfpenny* in the pound, and an inhabitant of Lombard-street *three shillings and sixpence* in the pound. There is surely something "very rotten" here!

ARCHITECTS' PECUNIARY RIGHTS.

A CORRESPONDENT in Belfast desires to be informed on the following question:—"An architect prepares plans and specification, which are approved of, and he is directed to procure tenders according to same. This being done, the client determines on carrying out the work in *two* portions, necessitating the preparation of new drawings and specifications, according to which tenders are *again* sought and received, and the work superintended to completion. *Query*—Is the architect entitled to charge for the drawing and specification in the *first* instance, he having been engaged in the *second* instance; and if so, what amount?"

Answer.—The fees to which an architect is entitled are 2½ per cent. for drawings and specification *only*, and if required to superintend, to an additional 2½ per cent.—total, 5 per cent on the *actual* value of the work provided for by the drawings, &c. Moreover it is customary when the tenders are received and the contractor declared, for the architect to draw his commission of 2½ per cent. for same, closing the transaction so far. In the case before us that point of right was reached when the *first* tenders were received, and consequently the architect is entitled to charge his 2½ per cent. thereon, independent of subsequent claims. For the second set of drawings, &c., if prepared *de novo* to suit client's wishes, and not from any misapprehension on his own part as to the expenditure intended to be incurred, the architect is also entitled to a second 2½ per cent. commission in addition to that for superintendence, which should be calculated on the *actual* expenditure according to same.

Of course, the above statement as to rights refers to the recognized *custom*, and is not presumed to offer a *legal* solution.

ARSENICAL PIGMENTS IN THE USEFUL ARTS.

THOUGH very much has been urged of late in the way of caution to the public against the adoption or use of such materials in the decorative arts as contain arsenical pigments, nevertheless, in the matter of "paper hangings," numbers refuse to be warned, but yielding to a gratification of vanity, because the colours so produced are gay and striking, they hesitate not to introduce into their dwellings deadly poisonous elements, which sooner or later, as incontrovertibly proved, act most detrimentally, if not fatally, on the system. Though we can expect but little of novelty of argument to be now infused even by the most scientific experimentalist into "the principle" of the objection, nevertheless the subject cannot be too often or too earnestly urged for public consideration, and with that view we refer to the excellently practical exposition of deleterious effects and their causes in an elaborate paper read by Professor Davy, the eminent chemist, at the late scientific meeting of the Royal Dublin Society. The Professor referred particularly to the beautiful pigment known as Scheele's green, and also to the colour of a higher tint, known as emerald green, both of which were of arsenical character. It is well known to medical men that the deleterious effects of these salts of arsenic were felt not only by the artizans employed in the manufacture of the room-paper, &c., in which they were used, but also by those who habitually occupied apartments hung with these papers. Doctor Apjohn, the distinguished chemical professor, had been one of the first who had called public attention to this subject. Doctor Healy, residing in England, wrote a letter thereon, stating that he himself had experienced a variety of painful symptoms from sitting in a room hung with green paper, coloured with arsenical pigment. He lost the use of his left side, and, when under medical care, removed to a room with another paper. He speedily recovered his strength, but on returning again to his study, where the green paper was on the walls, all his bad symptoms returned. He caused the paper to be tested, and it was found to contain arsenic in large proportion. He had the paper removed, and his health became restored. Dr. Taylor and Dr. Hynd had also commented on the subject. The professor cited several other cases wherein parties had suffered well-marked symptoms of arsenical poisoning by occupying rooms hung with paper of this kind.

A COLUMN FOR CRAFTSMEN.

HEREWITH we commence a series of articles embodying considerations on the pursuits of the numerous trades identified with the building profession, and which, though necessarily in a comparatively limited compass, is presented under increased trouble and expense, in grateful acknowledgment of the excellent support accorded, by the artizans of Ireland especially, to this national organ, THE DUBLIN BUILDER, since its first establishment, and with the sincere trust that it may conduce, even in a degree, to their combined instruction and enjoyment.

NO. I.—CARPENTRY.

Comparatively little of the actual history of the "carpentry art" has been transmitted to us by the ancients, yet allusions being made thereto even in Holy Writ, when in its rudest state, and subsequently in the works of Pliny and Vitruvius to "the selection and felling of timber," its employment by the Greeks and Romans, as well as those considerations which common sense will supply as to the wants of all the inhabitants of the earth at those and every period, no question can be raised as to its antiquity. Moreover, the members of the fraternity may, without the least disparagement to their brethren the masons, stonecarvers and cutters, bricklayers, &c.—to all of whom we shall, in future articles, endeavour to do every justice—claim some precedence for the versatility of handicraft assumed to be possessed by every skilled workman. The word CARPENTER is peculiarly comprehensive in its signification, and embraces under that title—derived from the French *charpentier* (*charpente*, timber), or more probably from the Latin *carpentarius*, an artificer in timber—more meaning than is ordinarily understood by the public. It may, however, be reduced to three heads—the *constructive*, the *descriptive* (a term applied by the celebrated Monze) and *joinery*; the first having reference chiefly to such portions of a structure as possess roughly the element of stability; the next, the application of geometrical principles to the fashioning of forms; and the last, the more ornamental and accurate portions, requiring great delicacy of manipulation, such as mouldings, mortising, tenoning, rebating, &c. Independent of these, there are numerous subservient departments, in which, as an accessory to the other trades, the skill of the carpenter is called into extensive requisition. In this or any other branch the craftsman of to-day, unlike his predecessors of some centuries since, has no excuse for not being pre-eminently a master in every detail—the best substantial precedents being, practically and theoretically, afforded him, within reach of his humble means, and from his earliest boyhood elementary instruction placed at his command, through Governmental sources, if he will avail himself of it. Nevertheless it must be conceded, that "progress" has not been compatible with the facilities presented, and that in workmanship—excepting so far as relates to economy of material—there is comparatively little distinction between the ancient and the modern artizan, and even in that regard the advantage is, and has been, too often perverted by those who indulge in false notions and overshoot the mark. The employment of iron in modern structures has caused a serious innovation on the carpenter's rights as established by usage; but though we live in a progressive age, when one spurred by emulation will surely endeavour to tread on the heels of him who leisurely precedes him, the carpenter nevertheless will—as he always did, since time immemorial—maintain intact, to a certain extent, his privileges; moreover, he can pride himself on being an indispensable requisite and auxiliary, now and for evermore, to his brethren, and that come what will in the shape of mechanical appliances, his craft will always *command* universal regard. It may not, perhaps, be out of place here to remark that in this craft especially "the Irish" maintain amongst their brethren of the United Kingdom a most prominent position for dexterity and skill; nor would it indeed partake of exaggeration to state, that their competency is universally acknowledged and appreciated.

The earliest proof afforded that the application of carpentry to the formation of human habitations contributed to the advancement of architecture is to be found in the primitive hut, whose upright, rude, and cumbrous posts unquestionably suggested the column, so classically fashioned subsequently, and whose horizontal and transeverse projecting beams are *said* to have originated the metopes and triglyphs of the chaste Grecian Doric order. Who but those who read and choose to understand illustrated facts would feel disposed to admit the possibility of such a simple "cause" producing so material an "effect" on the future of a glorious art.

(To be continued.)

AIR, SUNSHINE, AND FLOWERS.

Apropos to the movement at present on foot for the persuasion of the Royal Dublin Society to open for public recreation on Sundays the Botanic Gardens at Glasnevin, the committee have appealed by circular, partly under the above title and in the following terms:—

> "When the poor artizan has paid for the bare necessaries of existence out of the wages earned by incessant toil during six days, what has he left for rail or car hire to take him, his wife, and family out into the country to breathe the pure air, and enjoy themselves on the day granted them by kind Providence as a day of rest? How often may his little one appeal to him to gratify her longing for flowers and birds, and meet with the reply: 'These things are for the rich, not for the poor!' The child of the artizan is thus left to the gloom of a miserable apartment, or to run riot through lanes and alleys, demoralized and demoralizing. And why is this? Simply because the child has had the misfortune of being born in Dublin! In all parts of Continental Europe the public gardens, parks, squares, and pleasure grounds being freely thrown open, the poor man can go there with his family on the Sunday, and for a time forget his and their poverty, as they participate with the highest in the land in soul-elevating enjoyment and healthful recreation. Are *our* artizans, *our* tradesmen, *our* people so inferior to the English, or French, or Germans, that they are to be shut out from a Botanic Garden, maintained at Glasnevin out of the public taxes?"

STAINED GLASS.

The ancient Egyptians are said to have made and coloured small ornaments of glass, but it does not seem to have been much used by any of the ancients, though small pieces are found in Roman mosaics, and some larger plates have been discovered at Herculaneum, which are supposed by some to have been used as window glass. Stained glass for windows was probably in use as early as the ninth century, but no example exists in England of earlier date than the twelfth century, to which period belong the remains at Canterbury. These consist of panels of various forms containing subjects on a deep blue or ruby ground, the spaces between being filled up with mosaic patterns in which ruby and blue are the prevailing colours, the whole being surrounded with a border of foliage and scroll work. During the early English period the glazing consists of panels, circles, quatrefoils, and other forms, including that of the vesica piscis, and these contain subjects; the intermediate spaces are filled with coloured mosaic patterns, and the whole contained in a border of leaves and scroll work. Sometimes the entire space within the border is filled with scrolls and foliage, on a deep blue or ruby ground, the scrolls, &c., being either of coloured glass or only in black outline in plain glass; in the latter case panels formed by strips of coloured glass are sometimes inserted.

Quarry glazing, in which the windows are formed by lozenge-shaped pieces of glass with a small pattern in each, is first used in this style. In the decorated style quarry glazing becomes of frequent use, and the panel system loses ground; where panels occur, the ground is covered with patterns of foliage of a more flowing and natural character than in the preceding style; the vine and ivy leaves are favourites. Sometimes the entire window is filled with such foliage, which is often only in outline, and frequently only some portions of the pattern are stained yellow. Quarries contain small patterns of leaves, rosettes, &c., sometimes in plain outline, but frequently coloured yellow, in foliage patterns, in which the vine and ivy leaves predominate, the stalks of the leaves are often so arranged as to form one continuous flowing pattern throughout the window, and at other times one edge of each quarry had a coloured stripe, so that when put together they each appeared surrounded with a coloured border. The entire design is surrounded in most cases with a running border of foliage and flowers. At this period single figures surrounded by canopies begin to appear, at first in small size—two or more being contained in one light—but afterwards they became large, and were disposed one in each light. In the perpendicular period this practice begins to increase; the figures and canopies are of a larger size, more than one being seldom contained in one light; at last whole windows containing several lights were filled with one large grouped subject. Quarries still continued in use, but the devices do not flow one into the other, consisting mostly of rosettes, flowers, fleurs de lis, and heraldic devices, the latter being frequently and generally adopted in this style. Coloured inscriptions on bands or scrolls are frequently seen running diagonally and at regular intervals across windows, from top to bottom. With the decline of Gothic architecture stained windows fell into disuse, and with its revival it is now occupying a great deal of attention, and is executed by several manufacturers with considerable taste and skill.

INGENIOUS INVENTION—NEW FIRE-ESCAPE.

Ingenuity, in whatever channel it may be directed, always commands a certain amount of interest; but when the inventive faculty is brought into requisition in matters of philanthropic tendency, where the alleviation of human suffering or the saving of life is the object, its merits becomes considerably enhanced, and in according space for publicity of such, we always experience a two-fold pleasure. For the third time since the late unfortunate calamity at the Kildare-street Club House, our attention has been specially directed to models of contrivances, professing to supersede those now in vogue to facilitate the escape of inmates from burning buildings. On two of them we have already expressed our opinion, but to the subject of this notice we would urge more than ordinary consideration and appreciation. We may premise that an interesting feature connected with the matter in question is that the inventor is a mere boy, scarcely entered his "teens," and moreover a recent pupil of the Royal Dublin Society, by name William Clayton, residing at No. 40, Waterloo-road. In the absence of a diagram, which limited time prior to publication prevented us from including herewith, the following will be found perhaps sufficiently intelligible to convey a description of its particulars:—

The apparatus is designed somewhat on the telescope principle, being capable of elevation to any ordinary height—say 50 feet, but when closed is only 20 feet, or some 6 feet shorter than the present escapes. It comprehends three separate double ladders, each of different width to the other, the undermost being the widest—3 feet—and forming the framework of the escape, the second slightly narrower, and the third narrower again—so as to slide freely beyond each other, as may be required, according to circumstances. At one end of the framework thus formed, is a pair of ordinary five feet diameter carriage wheels, the axle of which also forms a drum, worked by a windlass, to elevate the ladders, and is the fulcrum on which the whole apparatus depends for raising to a required angle; at the other is a pair of smaller detachable wheels, to facilitate the locomotion in a horizontal position. Connected with the former is a box for spare ropes, windlass handles, &c., and a moveable framework, which thrown back offers perfect facility by a simple leverage action for elevating the ladder or ladders to any required position. Assuming, therefore, that it becomes desirable to supply the escape to a first floor window, the height can be attained by the apparatus in a folded state; or if a *second* or *third* floor are to be reached the simple turning of the windlass—before described as attached to the axle of the carriage wheels, on which revolves a single rope, passing through a pulley—serves to elongate the other ladders with extraordinary rapidity; but they are capable of being checked and held in their course as desired by the combined action of a pall on the drum, and a peculiar form of Z hinges, clasping the framework at the bottom of each length. In the construction of the ladders a much more than ordinary facility is afforded, owing to their width, and the sides are protected with trussed handrail and wire, so that without the brigadesman's assistance ascent or descent is easily accomplished. The divisional or vertical bar presents a travelling rail for the cradle to slide upon, a groove being formed in the back thereof prepared to receive it. The cradle, which is waggon-roofed with fire-proof material, it will be seen instead of—as at present—being placed at the back of the escape moves along the uppermost side of the ladders, and is impelled by a wire rope attached to its end, passing through a pulley at the apex of the escape, and thence to the ground, coiled round the drum, so as relieve the weight in the transmission of the living freight to *terra firma*. It is proposed to make the apparatus of ash and oak, and the inventor assures us that the entire weight would not exceed 600 cwt. As yet this is the most ingenious, effectual, and simple contrivance of its kind submitted to our notice; and in all probability the public will have an opportunity ere long of judging of the apparatus full size.

George A. Boyd, Esq., D.L., and Deputy Chairman of the Midland Great Western Railway, has most liberally placed his gallery of pictures at the temporary disposal of the committee of the exhibition in May next, at the Royal Dublin Society House.

A workman of Paris has just discovered a means of preserving water and gas pipes from rust, by enveloping them in a thick coating of clay. The city of Paris has granted the man a pension for life.

The Birkenhead Commissioners are trying the experiment of lighting the cabins of their river steamers with gas, a quantity of which will be carried on board each steamer daily.

MODERN ROAD CONSTRUCTION.*

As already noticed, the present generation is greatly indebted to the late eminent engineer, Mr. Telford, for the improvements in the construction of roads, but there are very many other names amongst our present professionals which should likewise be honourably associated with this department of the science. Foremost amongst them is that of Sir John M'Neill, who devoted his eminently practical mind and scientific research to this branch, and which have been called into extensive requisition, as regards the roads of Ireland especially, in the course of his professional career. As far back as the year 1836 we find Sir John pursuing experiments to show that the force of traction is in every case in an exact proportion to the strength and hardness of a road, the following being the results on a well-made pavement:—"The power required to draw a waggon is 33 lbs.; on a road made with 6 inches of broken stones of great hardness, laid on a foundation of large stones set in the form of a pavement, the power required is 46 lbs.; on a road made with a thick coating of broken stone, laid on earth, the power required is 65 lbs.; and on a road made with a thick coating of gravel, the power required is 147 lbs.: thus it appears that the results of actual experiments fully correspond with those deduced from the laws of science." And in same year, in his examination before a committee of the House of Commons, he said:—"The great advantage of the roads appearing by the machine is certainly in proportion to their solidity and their strength, and their want of yielding. If it could be a perfectly solid mass of stone or metal, the least resistance would be presented; that is shown both on stone tramways and on metal tramways, and metal rails."

From another source we learn that "this foundation should be composed either of a rough paving of large stones, or of a sufficient bed of concrete, the former being the practice of Mr. Telford, and the latter of many engineers of the present day; the selection of either of these materials will depend upon their economy in various places; whichever is most accessible, may be safely used; but whatever material be used, it is necessary that the sub-stratum should be of uniform strength and solidity over the entire surface, otherwise, after the pavement has been laid, the weaker parts will give way, while the stronger maintain their position, and so the surface of the road becomes broken and uneven, rugged, and full of hollows; for this reason we prefer the use of concrete, which offers greater security against this defect than foundation made of large stones or rubble, though in many roads even concrete is not sufficient entirely to prevent it. The concrete foundation should be slightly curved, falling from the centre towards both sides, which form will assist to drain it, and also to give the proper form to the surface of the roadway. It is necessary that this lower surface should be properly drained, otherwise the water will lie there, and destroy the road. If the concrete were laid 18 inches thick, we should not deem the extra expense ill laid out for a good road. With respect to the other kind of foundations, Mr. Parnell says—'In streets where the traffic is not very great, the foundation should be made in the following manner:—A bed should be formed, with a convexity of 2 inches to 10 feet, so as to admit of 12 inches of broken stone being laid upon it: these should be put on in layers of 4 inches at a time. After the first layer is put on, the street should be kept open for carriages to pass over it. When the first layer has become firm and consolidated, then another layer of 4 inches should be laid on, and worked in as before, care being taken to rake the ruts and tracks of the wheels of carriages, so that the surface may become smooth and consolidated. The same process should be repeated with the third layer of stones, by which means a solid and firm foundation will be established, of 12 inches in thickness, for the dressed paving stones to lie upon.' Such directions deserve greater attention than we fear they usually receive; in all cases let your foundation be secure before you lay your roadway."

Mr. M'Adam was the first to maintain the opinion that an elastic road was equally good as one with a firm, unyielding surface, and not only so, but even preferable. In a publication on the subject, he says:—"That the foundation or bottoming of large stones is unnecessary and injurious on any kind of subsoil. That the maximum strength, or depth of metal, requisite for any road, is only 10 inches. That the duration only, and not the condition of a road, depends upon the quality and nature of the material used. That freestone will make as good a road as any other kind of stone. That it is no matter whether the substratum be soft or hard."

"The resistance," says Professor Leslie, "which friction occasions, partakes of the nature of the resistance of fluids; it consists of the consumption of the moving-force, or of the horse's labour, occasioned by the soft surface of the road, and the continually depressing of the spongy and elastic substrata of the road. In fact, on a yielding roadway, the carriage or waggon has to be drawn over a series of hillocks, for, as the load passes over, it depresses that portion of the road immediately beneath it, and has before it, to be passed over in its turn, a portion which has not yet undergone this process. The comparison between the tractive power employed on roads of different elasticities, has been well illustrated—thus:—An ivory ball set in motion with a certain velocity over a Turkey carpet, will suffer a visible relaxation of its course; but with the same impelling force it will advance farther, if rolled over a superfine cloth; still farther over smooth oaken planks; and it will scarcely seem to abate its velocity over a sheet of fine ice."

Various kinds of materials are used for the purpose of forming the upper coat of the road, and amongst those most frequently employed may be mentioned broken granite, flints, gravel, and cubes of granite of various sizes. Of these the broken granite and granite cubes are most useful—the one for general purposes, the other for roads which are subject to great wear and tear, such as those in the principal thoroughfares of London and Dublin; for although both descriptions of material are used for this purpose, yet we are inclined to think that the broken stone is scarcely durable enough for such work; and there is this further objection to it, that it is constantly requiring repairs, which must, to a certain extent, inconvenience public business. Besides this, as usually managed, they occasion a great deal of dust and dirt, while the draught of vehicles upon them is very heavy, and their maintenance expensive.

In the first place, as regards durability, the objection would be removed to a considerable extent by employing a good foundation, and laying the metal carefully upon it, providing for the proper drainage of surface and substratum as mentioned above, for the lodgment of water either above or below such roads is very injurious, and tends, perhaps, more than anything else to their destruction. Having obtained a good foundation, the next point is to cover it with a hard compact crust, impervious to water, and laid to a proper cross section, so that it may be speedily drained and no water be allowed to remain on the surface, which, besides its inconvenience to passengers, is very destructive to the surface of the road. A practice has come into vogue of late, of covering the road when made with a binding composed of the grit collected off the road in wet weather, and by the operation of water sweeping. The binding is laid on regularly and watered until the new material is firmly set, which it does very quickly, and when the binding is of good quality and properly laid on, it assists its formation very considerably, and altogether improves the condition of the road and economizes the material, for it saves the wear and attrition of the new stone. Some road-makers object to this binding on the ground that it destroys or rots the road, and that when the road is set it has to be carted away again; but this is only the case where improper binding is used, such as is swept from streets which are not properly cleansed, and therefore consists principally of mud, and not of grit, or rather of grit so mixed with dirt as to be for the most part useless for binding. This method of binding a road removes in part the objection which is made against the resistance occasioned by the loose stones of a newly-laid broken road.

Roads paved with blocks of wood are of comparatively recent invention, and offer many advantages over common roads, in the evenness of the surface, but more especially by the prevention of noise, which is a great inconvenience on paved roads. It is to be regretted, however, that with such advantages it has defects, which, until removed, will put an effectual bar to its general employment; we allude to its want of durability, and consequent expense, but more especially to its slipperiness in wet and damp weather. The former objection we feel confident may be removed by employing greater care in the construction and drainage of the substructure; and the latter has been remedied in some degree by spreading broken granite on the surface.

The principal points to be attended to in the construction and maintenance of roads are—viz., a good solid foundation, proper drainage, and efficient cleansing.

Iron ore has been discovered at Ballypallady, the nucleus being in the second cutting on the railway line west of the station.

The Wexford Harbour Improvement Bill has passed the standing orders in Parliament.

NOTRE DAME.—The work of restoring the exterior of Notre Dame has been resumed, and they are now repairing the rose window over the southern entrance to the cathedral. The whole of the south portion of the building is to be restored according to the original design. This part of the church was originally commenced, as an inscription on the wall tells us, on the 2nd day after the Ides of February, 1257, under the superintendence of Jean de Chelles, architect, during the reign of St. Louis, at which time Renaud de Corbeil was Archbishop of Paris.

Correspondence.

THE WESTLAND-ROW TERMINUS.

TO THE EDITOR OF THE DUBLIN BUILDER.

Sir—Referring to your publication of the 15th February, I notice that you allude to a proposed extension of the Dublin and Wicklow Railway Terminus at Westland-row, with a principal front in Great Brunswick-street, and it strikes me to enquire, if you or your readers are aware, that it was contemplated by the original plan to extend the line across the former to that point in the latter street now occupied by Clarendon's horse repository? How much more desirable for public convenience—carrying the line to the very heart of the city—such a work would be than that stated to be contemplated? and it may not be amiss, should space permit it, for you to refresh the memory of the directors thereon.—Yours, &c., C. E.

[The proposed extension of the present terminus, alluded to in the paragraph, was officially denied by the chairman at a recent meeting, although communicated to us by a correspondent on whose veracity we relied.]

RAILWAY PROGRESS.

The Engineer to the Dublin and Meath line reports that "the works, owing to the difficulty of getting land, are more retarded than would otherwise have been the case, but late arrangements have been effected, and the contractors put in possession of a large extent of land on the division from Kilmessan to the Black Bull. On this portion of the line the works are being vigorously pushed forward. They will soon be in possession of more land, which will bring them near the point at which the direct line to Dublin is proposed to commence. At the Navan end; of rock and clay 128 000 cubic yards have been removed, 17,000 lineal yards of fencing made, six miles have been ballasted and are now ready for the permanent way. The viaduct over the River Boyne, of 196 feet span, has been completed; four public road bridges, four farm road bridges, and other necessary works have been constructed. These are 2,000 tons of rails, chairs, &c., on the company's ground; and 25,000 sleeper blocks have been delivered and are lying, part at Navan and part at Dublin. A short piece of permanent way has been laid from a public road to where the sleeper blocks are to be deposited preparatory to their being prepared by the cutting machine. This machine will be shortly at work, and thus remove the only delay to the laying of a portion of the rails. From Kilmessan towards the Black Bull the contractors are working over a distance of 5½ miles: 20,000 cubic yards of excavation and 10,000 cubic yards of ballasting have been removed; 6,300 lineal yards of fencing have been completed; and upwards of one mile and a half of the line formed. Two public road bridges and their approaches are finished, and four others, with various other works, are in progress.

The excess of expenditure on the Fermoy line was only £2,600.

The recent railway accident at Cork cost the Great Southern and Western Company £6,000.

The North London Railway Company being sued by an architect for damages in consequence of injuries received through an accident on their line, consented to a verdict for £550.

The bill for the third extension of the Great Northern Railway from Castlebar to Westport has passed the standing orders, and, being unopposed, will pass both houses.

The Midland Counties and Shannon Junction Railway Bill has also passed the standing orders.

Mr. Mullins, Ex-President of the Institute of Civil Engineers in Ireland, has been elected a director of the Great Southern and Western Railway.

The standing orders have been complied with for the Belfast and County Down Railway (Witney). The following bill has been withdrawn:—Killarney and Valentia and Monkstown Extension. The following postponed:—Great Southern and Western.

The Cork and Macroom Railway bill has been read a second time, and the prospects of the undertaking are said to be most favourable.

The rolling stock of the Great Southern and Western Railway of Ireland is £1,500 a mile.

The Malahide Viaduct.—This structure has been finally completed, and at a recent meeting of the Dublin and Drogheda Railway Directors, both the chairman, Mr. Murland, and Lord Talbot de Malahide took occasion to compliment the engineer, Mr. Harty, on the satisfactory manner in which the work was carried on under great obstacles, and without impediment to the traffic of the line.

Opposition to the Dublin Water Works Bill.—Petitions have been lodged by Trinity College, Lord Meath, the Midland Great Western Railway Company, the Wicklow Borough and Harbour Commissioners, Messrs. Brett, Toomey, Tighe, &c.

Notes of New Works.

The first stone of the new church of St. Fintan has been laid at Mountrath. It will be in the Gothic style, after drawings by Mr. John S. Butler, architect; Mr. Beardwood, builder.

A new Roman Catholic Church is to be built at Clare Island.

A new hotel after American fashion has been commenced at Bray, by Mr. John Brennan, a wealthy and enterprising gentleman, who has recently erected some houses on the Strand. It is thus described by the local correspondent of the *Freeman*: The front facing the Quinsborough-road—very similar to those of the other fronts, the building being somewhat of a square — presents four storeys above the basement, with 15 windows in each storey. The entrance will be composed of a fine portico, supported by eight Ionic columns, and ascended by a spacious flight of stone steps. Internal arrangements will comprise at least 155 bedrooms, a coffee-room, 20 by 40 feet; restaurant, 20 by 30; a great dining-room, 40 by 28, opening into a drawing-room, 30 by 40; some two dozen parlours and private sitting rooms will also be presented, the basement storey being allotted to kitchens, pantries, servants' rooms, &c.

Two superior class dwelling houses are in progress of erection in Harcourt-street, Messrs. Hall and Son, proprietors and builders, Mr. M'Alister, architect. We understand that it was originally contemplated to make the elevation of a novel and ornate character, which circumstances subsequently rendered undesirable.

A new glebe house has been completed at Fork-hill, according to plans by Mr. W. J. Barre, of Belfast, architect; Messrs. Hall and Son, of Dublin, the builders.

A new clock tower is to be erected in the Market Square of Letterkenny.

Mr. John P. Brady, of Galway, has been declared the contractor for the building of the new jetty.

Two important church structures have been built in the parish of Ballinaclally, County Clare.

The churches of Acton and Portadown, Co. Armagh, and of Killeshal, Co. Tyrone, are to be enlarged, according to plans by the Ecclesiastical Commissioners' Architects.

A new parsonage house and offices are to be erected at Kildare.

The town of Ballyshannon is about to be lighted with gas, and estimates are required for the execution of the reqnisite works.

The Tholsel, in Drogheda, containing the assize court, corporation offices, &c., is about to be modified, according to plans by Mr. John Neville, architect and C.E., county surveyor. The gaol in same town has also been undergoing alteration and improvement. We should, however, experience additional pleasure in noticing more *general* progress, which, as regards building operations, is not in fair proportion to that of other towns of equal commercial position. In sanitary matters the deficiency is fearfully manifest, and seems rather on the increase than otherwise.

A limited competition is about taking place amongst local architects for the erection of a new building for the Royal College of Surgeons, on the site of the old Kildare-street Club House, destroyed by fire.

Another competition of similar character is also going forward for a new house of worship for Unitarians, at Stephen's-green.

BANKRUPTCY AND INSOLVENCY.

In re Hugh Kelly.—Meeting for surrender, proof of debts, and choice of assignee. The bankrupt's liabilities amounted to about £18,000. Application was made to appoint as assignee Mr. Thomas Ball, a creditor for £324, and again on behalf of Messrs. Andrews and Alexander, of Belfast, creditors for £1,191, in favour of whom the majority of the creditors voted. To the latter objection was offered on the ground of "undue preference" in contemplation of bankruptcy.

The bankrupt, on examination, stated that last November he paid a bill of £700 to the latter, and subsequently on same day he received a telegram from Messrs. Patterson and M'Cully, of Liverpool, stating that a bill of £780, payable to them, fell due same day. Had no entrance of same, but in answer said he thought he would pay Liverpool creditors in full, as there were £508 due to him on a contract; did not intend to make any undue preference.

The Court said there was no imputation on Messrs. Andrews and Alexander, but as a question of "undue preference" had been raised, better appoint some other party.

Mr. Thos. H. Carroll was then appointed assignee.

Killen and Cunningham.—Meeting for final examination of bankrupts. Mr. Perry, on the part of the latter, applied for adjournment, and stated that he understood the estate would realise 20s. in the pound.

Review.

Brief Sketches of Booterstown and Donnybrook. (Second Part.) By the Rev. Beaver H. Blacker, A.M., Incumbent of Booterstown. Dublin: Geo. Herbert. London: Bell and Daldy.

When the first part of this little work reached us, we were justified and pleased in according to it a favourable notice. The sequel now before us is equally entitled to commendation, and the "painstaking compiler," as the author modestly terms himself, will doubtless reap both the honourable and the substantial benefit so justly due to his devotion to ecclesiological and archæological research. A lithographed copy of Yarranton's survey of Ringsend in 1674 is appended, and is characteristic of the eminence (?) attained in engineering draughtsmanship at that early period.

Miscellaneous.

New Hall, Kensington Gore.—This building, now in course of completion by the Royal Horticultural Society of England, at their gardens in Kensington Gore, London, is thus described by the *Gardener's Chronicle*:—" It is placed on that side o' the Garden next to the Exhibition Room, and is approached by a spacious carriage sweep on the east side, and on the west opens directly into a portion of the colonnade which surrounds the garden. The exterior is as yet in quite an unfinished state, but the interior is sufficiently completed to be available for the purposes for which it was intended. The Hall is sixty feet long by forty feet wide, and thirty feet high, a portion of this space being, however, occupied by architectural details. Its sides are formed by columns and pilasters of Roman Doric, surrounded by a handsome cornice, from which a series of semicircular arches takes its source. Three of these arches, on the east and west sides respectively, furnish openings which are to be used as entrances when required, forming a passage into the garden through the colonnades, and are at other times closed up by means of Clarke's patent revolving shutters. A fourth arch occupies the centre of the north end, and another the south, and in these are placed the entrances for ordinary use. The four angles are fitted with large mirrors, and above them, occupying the spaces between the arches, are several window-like openings to be fitted with ornamental castings, and intended to aid in ventilation. The ceiling consists of horizontal lights of ground glass, through which the gas pendents descend. The floor is paved with Minton's encaustic tiles. The heating is effected by means of hot water, the pipes for which are carried beneath the floor in channels covered by ornamental gratings."

Petroleum, or Mineral, Oil in Ohio.—This useful material has been discovered, according to the American *Gaslight Journal*, in another of the (dis-) United States. Two hundred rock-oil wells, as they are called, have been sunk in Warren County, Ohio, of which fifty to seventy-five are said to pay well. Thirteen steam pumps are in operation, and more are being set up. The average yield is 3,000 gallons per day, and more wells are being sunk.

The Geology of the Vartry.—Professor J. Bete Jukes, referring to the proposed water supply of Dublin from the River Vartry, says:—" The valley of the Upper Vartry (the part above the Devil's Glen) is mostly in Cambrian rock; its western side only consisting partly of lower Silurian. No drainage from the granite, and scarcely any from the mica schist, runs into the valley. None of the mines of Wicklow are in a Cambrian district, or even very near to one. The chances are, therefore, so far against the upper valley of the Vartry becoming a mining district. It is by no means impossible, so far as I am aware, that mineral veins should exist in Cambrian rocks—on the contrary, I believe there are some in Merionethshire in that formation. Whatever chance there may be for or against the rocks (either Cambrian or Silurian) which bound or lie below the upper Vartry containing mineral veins, there is an absolute certainty that the low ground traversed by the canals contains them. Any argument against the Vartry scheme derived from the possible existence of mineral veins in that valley, tells with double force against the canals, and would, moreover, be equally good against any scheme that could be devised."

A Cement for Glass.—A transparent cement for glass, it is said, is made by dissolving one part of Indian-rubber in chloroform, and adding sixteen parts, by measure, of gum mastic in powder. Digest for two days, and frequently shake the vessel in which these substances are contained. The cement is applied with a fine camel's hair brush.

The Great Britain Art Union.—From a correspondence that has appeared recently in the daily papers, originated by the secretary of this association, it would seem that the large sum of *ten pounds* was expended in the purchase of prizes at the Royal Hibernian Academy Exhibition, although " the liberal support of the Irish public" is acknowledged with thanks, and that said Art Union is established to encourage art *equally* in Ireland as in England and Scotland. The *result* certainly does not bear out the *profession!*

The Magnetic Telegraph Company.—The facilities for sending messages by telegraph appear to be gradually approaching the conveniences of our postal system. The Magnetic Telegraph Company are now issuing small adhesive stamps for franking messages throughout their lines in the United Kingdom. The principle is precisely similar to the postage stamp system. A message can be written wherever convenient, and, after affixing the necessary stamp, it can be sent either by post or messenger to the nearest magnetic telegraph station, and thence forwarded to its destination. There is said to be a liberal discount on these stamps in order to assist in bringing them into general use.

The British Museum.—The Department of Antiquities at the British Museum is to be divided into three sections, which will be placed under the care of Mr. Birch, Mr. Newton, and Mr. Vaux respectively. Mr. Newton's great and successful labours at Halicarnassus and Cnidus are fresh in the recollection of the public, and afford the best guarantee of the advantages that the Museum may expect from his appointment. The Archbishop of Canterbury, the Lord Chancellor, and the Speaker of the House of Commons have exercised their powers as Governors of the Museum with an anxious desire to secure the best men for the public service, and this infusion of new blood into an old establishment cannot fail to be of signal advantage.

How much Money is there in the Country?—The *Mechanics' Magazine* publishes a statement of the quantity of gold, silver, copper, and bronze coin at present in circulation throughout the United Kingdom. The number of gold pieces amounts in value to at least £100,000,000. Silver—Crowns, 2,320,027; half-crowns, 37,516,343; florins 10,000,000; shillings, 112,554,106; sixpences, 76,132,578; fourpences, 20,142,034; threepences, 7,572,437. The total current value of the copper coin is £1,250,000, and its weight 6,000 tons. Several hundred tons of bronze coin have also been issued, making the total number of coins in circulation throughout the British isles nearly 900,000,000.

THE THEATRE ROYAL.

At the Theatre Royal the pantomimic star " is still in the ascendant," though a supposition of its brilliancy being somewhat clouded might not in this, " the Ides of March," be unreasonably entertained. It has now been visible to the Dublin public for a period of upwards of two months—an unprecedented run—but affording the best possible proof of its refulgent powers. Having already alluded to it we will not add further than that (divesting metaphor), next to the scenic attraction, the vivacious acting of Mrs. Burkinshaw, a host in herself, justly claims our commendation.

To Correspondents.

C. R., Sligo (Custom of neighbourhood would partly determine; the old general custom, as admitted, was 1 foot superficial of extra labour for every foot lineal of hips and valleys to carpenters' work, and in slaters' same quantity of materials and labour for hips, valleys and under eaves; the only extra *now* admitted is eaves, or rather under eaves, generally 1 foot additional. Measurement of stone work as regards labour does *not* include beds, and was met by an *extra* charge); "Traveller" (Undesirable for insertion); E. W. O'R. (Send tracings early); W. T. M. (Elsewhere replied to); "Draughtsman," Belfast (Your better plan is to advertise when ready); J. H., Bermingham (Expecting, as advised.)

NOTICE.

Post-office Orders and Remittances should be made payable to Mr. Peter Roe, *Printer and Publisher*, 42, Mabbot-street, Dublin.

☞ *NOTICE.—All Communications respecting Advertisements, Subscriptions, &c., should be addressed to "The Publisher of the* Dublin Builder," 42, Mabbot-street. *All other Communications should be addressed to the "Proprietor and Editor,"* 17, Lower Gardiner-street.

TO ENGINEERS & SURVEYORS, ARCHITECTS, ETC.

MAPS, BUILDING PLANS, SPCIFICATIONS, and DRAUGHTING of every description executed at the lowest terms in the best style.

W. F. CONROY,
Office, 10, Fleet-street.

WANTED, a respectable Young LAD, as Apprentice to the above. Respondent must have a slight knowledge of Drawing, and write a fair hand.

MESSRS. ISAAC & W. R. FARRELL,
ARCHITECTS, ETC.,

Beg to inform Builders and others that they have added a MEASURING and VALUATION BRANCH to their Office, for which they have secured efficient Assistants, to enable them henceforth to supply Estimates, Valuations, and Measurement of Artificers' Works, as formerly carried on for many years by Mr. ISAAC FARRELL, of this Firm.

OFFICE—25, LINCOLN-PLACE.

TO CONTRACTORS.

MR. WM. DOOLIN, BUILDING SURVEYOR and MEASURER, is prepared to afford Contractors all information as to prime cost on all material; take out Quantities, and prepare Estimates.—Offices, 27, TALBOT-STREET.

MESSRS. JAMES & EDWD. BARKER,
CONTRACTORS
To Her Majesty's War Department, and the Ecclesiastical Commissioners for Ireland.
All orders executed to satisfaction.
32, UPPER ABBEY-STREET, DUBLIN.

W. MAXWELL,
ARCHITECTURAL ENGINEER AND ARCHITECT,
BALLINASLOE.

MESSRS. TELFORD & TELFORD,
ORGAN BUILDERS.

Several new and second-hand FINGER & BARREL ORGANS, suitable for Church or Chamber, will be sold on very reasonable terms, to make room.

109, STEPHEN'S GREEN, DUBLIN.

GEORGE TICKELL, Wholesale and Retail CABINET MANUFACTURER AND PLATE GLASS FACTOR, 17, 18, 19, and 20, MARY-STREET. FACTORY—29, STAFFORD-STREET, DUBLIN. Importer of Cabinetmakers' Mounting and Upholsterers' Trimmings. G. T. would beg leave to call attention to his Upholsterers' Goods.

Prompt attention paid to written orders.

T SQUARES—W. F. STANLEY'S
IMPROVED.

Recommended in "The Engineer", and "Builder." 42 in., 5s. and 7s. 6d.; 31 in., 3s. 6d. and 5s. 6d.; 23 in., 2s. 6d. and 4s. Improved Architects' Scales, Boxwood, 2s. 6d.; Ivory, 8s.; by post. Improved Architects' Drawing Instruments. List of Prices on application.

MANUFACTORY—3, GREAT TURNSTILE, HOLBORN.
LONDON, W. C.

NOTICE.

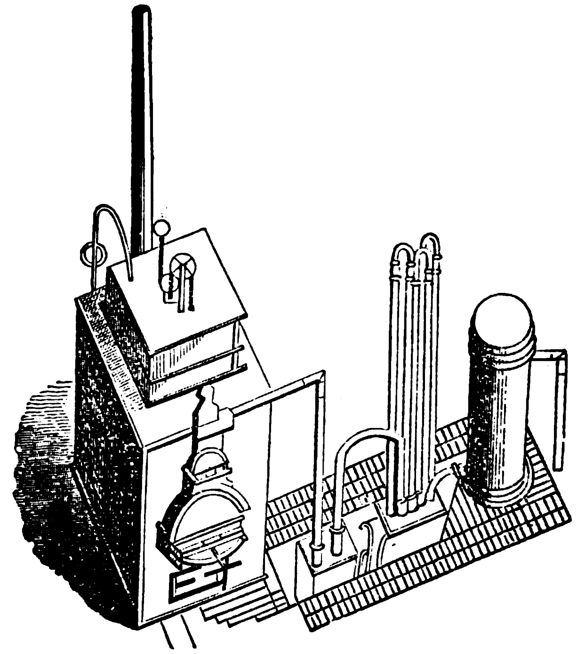
Gentlemen—To correct the impression that my premises and stock at 3, Great Turnstile, were consumed by fire on the 29th of January, as might be inferred from the reports in the London daily papers. I beg to state that three of my workshops only were burned, which were situate 3 houses from my selling shop. I can further assure my customers they will be served as heretofore with instruments of the best possible make, having taken more extensive premises for workshops, to meet my extending trade.

Yours obediently,
WM. F. STANLEY.

SURVEYING, ENGINEERING, ARCHITECTURE, &c. — PRACTICAL INSTRUCTION is given in SURVEYING, Levelling, Civil Engineering, Architecture, Building, Draughting, Mapping, Measuring and Valuing of Land, Timber, Buildings, &c., by Messrs. HYDE, SMITH, and LEWIS, Civil Engineers, Architects, Surveyors, etc., in a short Course of Instruction on moderate terms, including FIELD WORK and the use of the INSTRUMENTS. For Prospectuses, apply at the Offices, 24, Guilford-st, Russell-square.

N.B.—An Architectural, Engineering, and Mechanical Class for Architects, Builders, Engineers' sons, etc., on moderate terms, including instruction in Drawing, Coloring, Taking out Quantities, etc.

It is simple and inexpensive, and can be managed by any labourer or servant; is quite free from all unpleasant smell, and produces more Gas from a Ton of Coal than any other Apparatus.



The Price is regulated according to the size of the Apparatus, and will be found even lower than the old description of Works.
THE LIGHT PRODUCED IS PURE AND BRILLIANT.

PATENT HYDRO-CARBON GAS APPARATUS.

JOSHUA EDMUNDSON & CO. are Manufacturers of the above Apparatus, which is adapted for Lighting Towns, Noblemen's and Gentlemen's Mansions, Colleges, Mills, Manufactories, Railway Stations, Farm Steadings, &c.

Estimates for all parts of the Kingdom given Free of Expense.

All information will be furnished on application to

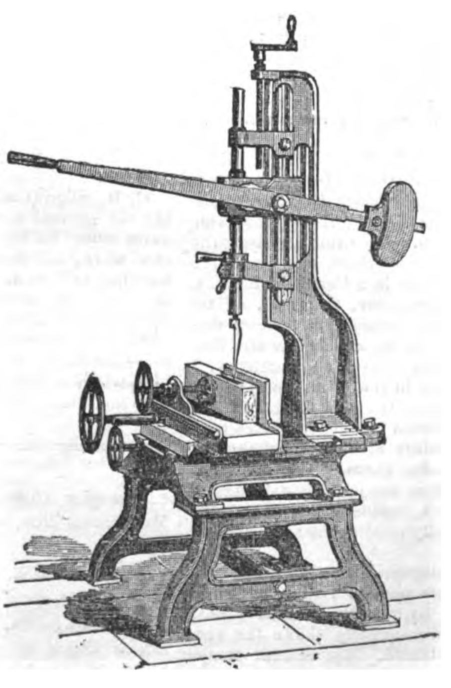
J. EDMUNDSON & CO.,
Brass and Iron Founders, and House Furnishing Ironmongers;

Agents for *Milner's Fire-proof Safes and Boxes*; also for *Goddard's Patent Economical Cooking Apparatus, &c.* Smiths' and General Iron Work, Plumbers' Work, Bell-hanging, &c. on the most approved principles.

34, 35, & 36, CAPEL-STREET, DUBLIN.
MANUFACTORY—49, 50, AND 51, STAFFORD-STREET.

GALLON AND BEAN, LEEDS,

Cut & Wrought Nail Manufacturers, & Hardware Merchants,



RESPECTFULLY request all BUILDERS, CONTRACTORS, CARPENTERS, &c., requiring Mortising Machines, previous to purchasing, to examine and test *their patent combined Crank and Lever Machine*, which will Mortise (Tenon and Bore, if required) both Hard and Soft Wood, and is also adapted for Drilling and Punching Iron.

The superiority of this Machine over *all* others consists *in the substitution of a solid wrought-iron plate Crank or Eccentric, by which greater power is obtained, in place of cast-metal Rack and Pinion Wheel, the Teeth or Cogs in which are so liable to strip or break out*—in the direct and perpendicular action of the Lever and Crank on the Cutting Tool, and consequent diminution of friction—in being *stronger* and *less complicated* in its construction, and more *powerful* in its motion—in the *facility* of its *adaptation* to the various depths of material—and in its *non-liability to break* or get out of working order.

This Machine has now been adopted in preference to *all others* by some of the principal Builders in London, Glasgow, Edinburgh, Dublin, and Belfast, who will bear testimony to its being the most powerful and efficient yet made

For further particulars apply to the Patentees and Makers, GALLON, BEAN, and LUMB, LEEDS.

Extract from the Report of the Royal Dublin Society's Spring Show, 1859:—

"Gallon, Bean, and Lumb, Leeds, exhibited a very useful and complete Mortising Machine, which was highly commended."

N.B.—The Patentees respectfully intimate that this Patent extends to, and comprises Machines for Mortising by Steam and other motive power, as well as by hand; and makers and vendors of, or parties buying or using Mortising Machines, *are cautioned against any infringement*, as the patent right will be strictly maintained.

The Dublin Builder.

VOL. III.—No. 30.

THE VARTRY PROJECT—PATERNITY, CAPACITY, AND COST.

A CLAIMANT for the paternity of the Vartry project, as recommended by the Royal Commissioner, Mr. Hawkshaw, C.E., as the best source for supply of water to the city of Dublin, has appeared in the person of Mr. Hassard, C.E.; and the latter gentleman complains "that although his scheme has been recommended by the Royal Commissioner, and adopted by the Corporation, yet his name does not appear in the commissioner's report as associated with the Vartry project, otherwise than as an appendix, although his name is put forward on the plan accompanying the report in connection with another scheme for taking water from the canals, which he laid before the Pipe Water Committee in 1854." A grave charge from one professional gentleman against another; and although there is an unquestionable *prima facie* evidence of a good foundation therefor, we feel quite assured—judging from the high reputation of the eminent engineer honoured with her Majesty's commission to investigate and report on this question—that the matter complained of was more the result of *oversight* than *design*, and that on representation the *amende honorable* will be cheerfully accorded. However, be that as it may, there is a striking similarity between the *modus operandi* proposed by each of these gentlemen; in fact, excepting some comparatively insignificant modifications, the scheme originally submitted by Mr. Hassard is unquestionably that proposed for adoption by the Royal Commissioner; but as Mr. Mullins, C.E., chairman at the meeting of the Institute of Civil Engineers, on Wednesday evening last appropriately suggested, that "as Mr. Hassard claimed the *paternity* of the design, so also should he be prepared to undertake the responsibility;" we echo the sentiment, and submit that if any weight be attached to the projects of the other eminent professional gentlemen, or to the objections advanced by the opponents of the Vartry as a source of supply, either from its incapacity or its expensiveness in constructing the requisite works, should failure to any degree result, the claimant will require to have the shoulders of Atlas to sustain the weight of public odium sure to follow. Mr. Hassard, however, has made most careful calculations; he has studied the geographical and geological formation of the line between the valley of the Vartry and this metropolis, and is confident both that it is the best source for *quantity* and *quality*, and, moreover, that the expenditure to be incurred need not exceed £250,000. Nay, further, we understood Mr. Hassard to remark, *sotto voce*, that he should wish to have the contract for that amount. Well, this to a certain extent *is* a guarantee afforded by a competent professional engineer; but while attaching all due importance to his competency to form a judgment, we are nevertheless not disposed to regard it as *conclusive*. The *greatest mistakes* have sometimes been made by the *greatest men*. Let us now consider the question of *capacity*. Mr. Hassard maintains, that although "as far as he is aware no rain guages had been kept in the locality," yet, judging from observations made at Ballysmuttan and Dublin, respectively, an average annual rainfall in the Vartry valley will be 29·08 *plus* 11·62 = 40·70 inches, and in a very dry year, such as 1847, 24·04 *plus* 9·61 = 33·65 inches; further, that from this is is to be deducted the loss from evaporation and absorption, varying in similar formations from sixteen inches downwards, sometimes in hill districts falling as low as ten inches. In this instance, however, "as the upper portion of the collecting ground is steep, from which the water would flow off rapidly, and as the quantity of spring water in the lower portion is considerable," he considers that "it may be taken at fourteen inches, leaving 26·70 inches of rain as available in ordinary years, and 19·65 inches in a very dry year, such as 1847. The quantity of water obtainable will be as follows .—

			Gallons.	
At 24 inches of available rain,	..	..	24,823,230	daily
23 "	..	..	23,788,939	"
22 "	..	..	22.754,628	"
21 "	..	..	21.720,327	"
20 "	..	..	20,686,026	"
19 "	..	..	19.651,724	"
18 "	..	..	18,617.421	"
17 "	..	..	17,583,120	"
16 "	..	..	16.548,820	"

being rather more than 1,000,000 gallons daily for each inch of available annual rain-fall."

This is clearly a theoretical calculation, on the ascertained data that at Ballysmuttan—the site for the proposed reservoir—during a certain six months the average rain-fall was greater by 60 or 70 per cent. than that of Dublin, and that consequently, taking the Vartry rain-fall at *two-thirds* less than that of Ballysmuttan, an average of 40 per cent., yielding a minimum supply of 18,000,000 gls. per diem, may reasonably be assumed. How is this theory met by the opponents? Professor Galbraith—who, at least, it must be conceeded is competent to form a common-sense opinion—visited the locality on Tuesday, and states that "no rain fell there on that occasion, but that heavy clouds hung over the Jouce mountain and the adjoining hills. On the next day he went to the neighbourhood of Lough Dan, and was told by the residents that they had *a very heavy fall of rain there* at the very time that the catchment basin of the Vartry *was entirely free* from it." Moreover, the rev. and learned Professor believes that "from the configuration of the catchment basin of the Vartry, the rain-fall is not so great there as on the hills that bound on the western side; and that, the water that falls in that district might be said to be laid out to dry, exposed as it is on a flat surface to the sun and wind, which would cause evaporation to be greater than what Mr. Hassard calculated upon."

Again, Mr. Mallet, C.E., a gentleman of an eminently practical mind and who has devoted himself to the special consideration of the subject, maintains that "*far more water is obtainable from the Vartry than will be required to supply the city*," but is not an advocate for the scheme, believing that paramount objections of a totally different character are presented thereto. We need not here stop to consider *all* that has been urged by the advocates of the scheme on the one hand, and the opponents on the other, having already in our pages allowed every latitude for expression of the opinions of both, but one abstract fact is incontrovertibly apparent, viz., that *as yet there are no means afforded by practical experiment as to the capacity of the Vartry.*

Next, and lastly for the present, as to *the cost.* Mr. Hassard estimates the actual expenditure for works according to his plans to be £250,000, including the necessary reservoirs, conduits, &c., but with other contingent expenses amounting to £300,000! Mr. Mallet urges that "£400,000 will be nearer the mark;" others maintain that either of the above amounts are only about *half* what will be required. A trite though not very classical proverb reminds us that "between two stools one falls to the ground," and indeed unless prompt action one way or the other be brought to bear on the present question, it seems to our mind to be rapidly approaching that finale. "Better bear the ills we know, than fly to others we know not of," and better continue to drink the water at present supplied, than rush recklessly into a responsibility of £300,000 (*query* considerably more), till both the capabilities of the source be ascertained by *practical data*, and *unquestionable security* afforded of the works being constructed within the stipulated amount.

We must not be misunderstood as reflecting on the Vartry project, or questioning the good faith of its promoters; but we should wish to see their professions practically demonstrated before it is too late to retrace steps.

A rather extensive scheme for the establishment of schools of art throughout England is talked of in artistic circles. The want is too palpable.

Mr. Train has a permissive tramways bill before the house for the United Kingdom, while Sir. E. Colebrook has one for Scotland.

THE LAWS OF MOTION.[*]
